Now that the cold season is drawing near, various companies prepare anti-freezing solutions for the use of the automobilists. A different course is being adopted by the Automobile Equipment Company, 225 Jefferson avenue, Detroit, Mich., which sells what is called Natural Mineral water for the radiator. This solution is added to the radiator water as the latter is evaporated and does not freeze above a temperature of 40 degrees below zero.

Gilmer Improved Repair Pliers

G. Walker Gilmer, Jr., 51 North Seventh street, Philadelphia, Pa., has just brought out a new and improved type of his tire repair pliers which come in very handy in the making of speedy cures on tire casings. Since it is necessary for the efficacy of a cement repair on a casing, that the wound be absolutely clean before the cement is applied, lest the fabric rots, the pliers have been so designed that by their use the wound of the casing may be spread sufficiently wide to permit of thorough cleaning of it. The pliers sonsists of a triangular shank which carries at one end the jaw I_1, Fig. 2, while pivoted to it is the shank S_3 which

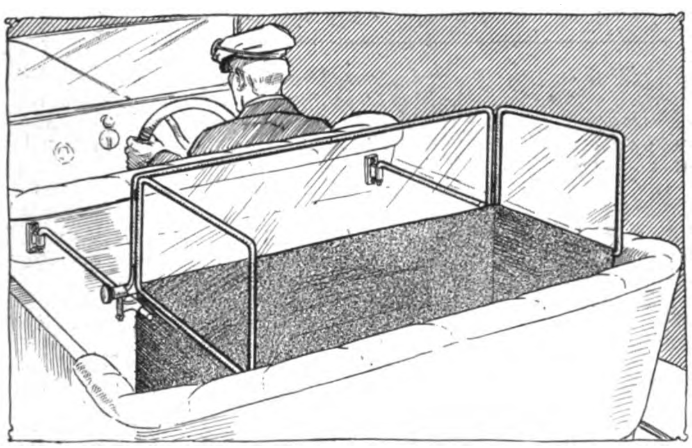

Fig. 4—J. H. tonneau windshield in place on touring car

is formed with a jaw I_2. The triangular shank consists of two side-members S_1 and S_2 which are held together by a rack-shaped connecting piece R, all being made of one piece of metal. A rod pivoted in the under side of S_3 drops into the teeth of the rack, as S_3 is moved in the direction indicated by the arrow, so that two jaws may be held in any relative position within the their limit of movement. To release the hold of the jaws, the button B is pressed toward S_3, whereby the hold of the inner rod of this shank on the rack R is relieved. The shape of the jaws

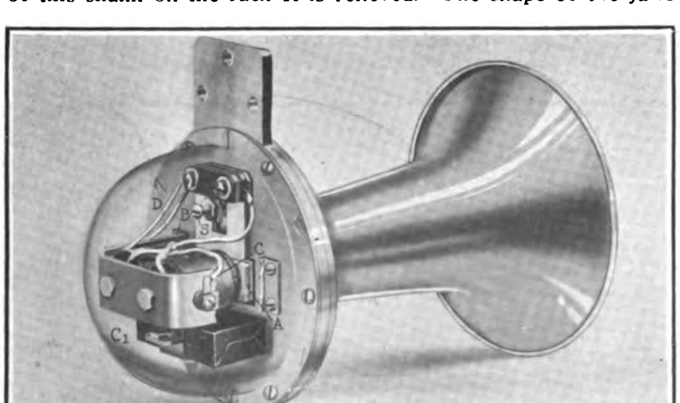

Fig. 5—Ghost view of Holtzer-Cabot automobile horn

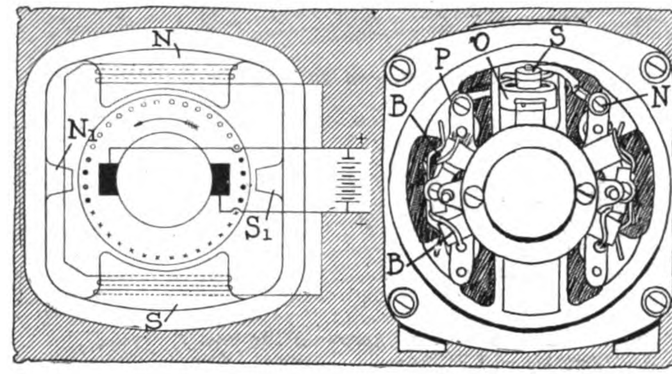
is clearly seen in the illustration, as in the form of the cleaning tool, which serves for the removal of foreign matter out of the wound. The pointed end of the tool serves for this purpose, while the flat end is designed for the pressing of the repair cement into the wound. The entire outfit is nicely finished in nickel.

Holtzer-Cabot Electric Horn

Another electric-vibrator horn has made its appearance on the market of Holtzer-Cabot Electric Company, Brookline, Mass. Fig. 5 shows this product, which operates on the same principle which has been repeatedly described in connection with various



Figs. 6 and 7—Details of Broit car-lighting dynamo

vibrator horns shown in these pages of late. A vibrator coil C and an armature A serve for actuating the acoustic diaphragm D, the vibration of which produces the signaling sound. The coil is mounted on a base B insulated from the other metal parts of the horn, and the armature which has a flat steel-spring part permitting it if reciprocating toward and away from the coil, serves as current breaker between the screw S and the metal casing C, through which the current returns to the battery. A push-button is used for actuating the horn.

Portland Automobile Turntable

Garage owners should find the automobile turntable made by the Portland Garage Company, Portland, Me., of interest. This table, Fig. 8, is distinguished by the cantilever principle applied in its construction, as well as by the ease of installing it in a garage. The table plate is carried by a cylindrical drum, which is concentrically mounted on a center pin, being carried by a baseplate mounted in the same manner, but resting upon the foundation. The table plate, which is of 10.25-inch steel, has a cast-iron center and its periphery runs within an outside ring, a clearance of .25 inch being provided between it and the ring. As the weight of the turntable does not rest on the central pivot itself, the latter permits of easy rotation of the table, and a minimum of friction is insured by the use of case-hardened rollers which run on the base carrying the weight of the table. The table may be installed in either of two ways, depending upon whether it is put on the ground floor or not. If there is a floor below that on which the table is placed, the latter must be set upon I-beams resting on the floor; whereas, when the ground floor is used, a single I-beam is buried and cemented in the ground, and the table placed upon it. This turntable is made in four sizes, having 10, 12, 13.5 and 15 inches diameter respectively, and having a maximum capacity of 106, 132, 151, 171-inch wheelbase cars respectively.

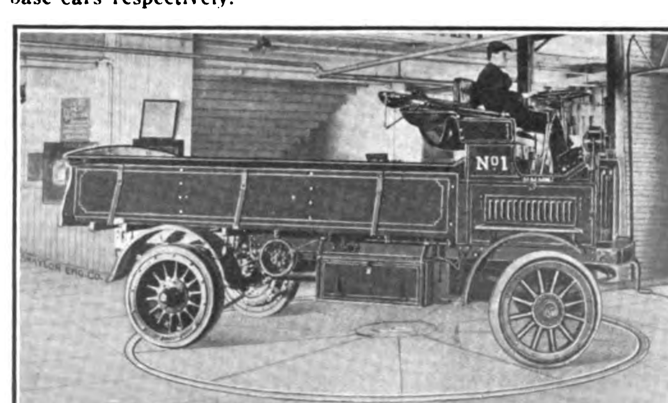


Fig. 8—Portable Garage Company's automobile turntable

AUTOMOBILE MOTOR ATTACHMENT—Comprising a chamber connected to the cylinder head, through which the mixture enters and where it is fired.

This patent has reference to an engine attachment, Fig. 1, which consists of a hollow, elongated body which forms an auxiliary chamber communicating with the combustion space of a motor cylinder through a passage P. The attachment has an enlarged portion E at one end and a reduced one R at the other. In one end of the attachment chamber an inlet vent I is formed which is separate from the interior of that chamber, but which contains a valve V opening into the reduced portion R of the attachment. This valve serves for regulating the admission of fuel mixture to the combustion space of the cylinder, through the attachment; a spark-plug P_1 is mounted in R and in alignment with V, so that it is in a convenient position for exploding the entire charge.

No. 1,043,643—to William H. Tatman, Wann, Okla. Granted November 5, 1912; filed September 16, 1911.

Check Valve for Tire Tube—Which contains a perforated stop for the stem to limit its movement during inflation.

The subject matter of this patent is a tire valve, Fig. 2, comprising a valve stem S to the outside of which a valve casing C is coupled, the latter being provided with a valve seat S_1. A valve V is normally forced against the seat by the air pressure inside the tube. To arrest the movement of the valve stem during inflation a perforated stop is the valve casing is provided; this stop is located some distance away from the valve seat, and a washer is in position between the stop and the end of the valve stem and compressed between them.

No. 1,043,224—to Cyrus A. Haas, St. Louis, Mo. Granted November 5, 1912; filed July 24, 1909.

Resilient Automobile Tire—In which a series of coiled springs inside of arched springs supplant the inflated tube.

Fig. 3 illustrates the tire described in this patent in place on a rim R. This rim has lateral inward side flanges forming a pair of bead-engaging rings on it. The tire consists of a number of separate, resilient units R_1, each of which is composed of an arched spring having inwardly turned ends at its base. A base-plate P composed of two members carried respectively by the inturned base ends of each arched spring is secured to the outer end of the latter. The projecting portions of the base-plate members engage under the rim flanges, their inner ends being rabbeted. By the use of means S a number of the base-plates are secured to the rim, so as to prevent the tire from creeping on it. Resiliency is obtained by a transverse series of coiled springs C, positioned in each arched spring and secured to the same at their outer ends; the outermost spring C seats upon and is fastened to the inturned ends of the arched spring, while the others are fastened to the base-plate members. T is the tread fastened at F.

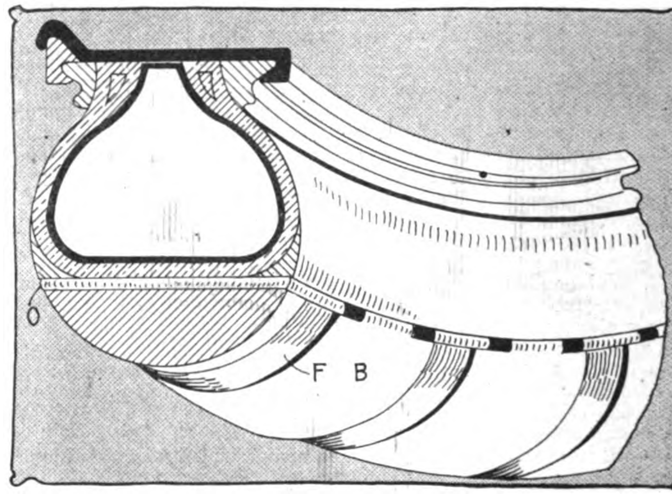

Fig. 5—Dennis pneumatic tire with block-type tread

No. 1,043,642—to Horace A. Stoneham and Carl T. Schwarze, South Orange, N. J. Granted November 5, 1912; filed January 16, 1912.

Demountable Rim Construction—Consisting of three segments which are hinged together in a suitable manner.

The demountable rim described in this patent is seen in Fig. 4. It consists of a pair of main segmental sections M which are connected by a hinge H. A relatively short segmental section S is designed to fit between the ends of M which are not hinged together and is connected to M by means of hinges K. The hinges K include link members which permit of a slight inward movement of the short section, as shown in Fig. 4, when the tire is taken off the rim.

No. 1,043,714—to André Jules Michelin, Paris, France. Granted November 5, 1912; filed May 2, 1911.

Pneumatic Tire Construction—Having a chordlike wall to its casing and a set of tread blocks attached to the same.

This patent relates to a tire having an outer casing O, Fig. 5, formed with a chordlike periphery. A number of blocks B spaced around the circumference of that chordlike part of the tire and individually attached to it form the tread surface. Each block has its surfaces shaped to fit the outer wall O, and to hold the blocks in the proper spaced relation, filling pieces F are in place between adjacent blocks and attached to O.

No. 1,043,407—to Alfred A. Dennis, Grand Rapids, Mich. Granted November 5, 1912; filed February 24, 1912.

VOL. XXVII NEW YORK—THURSDAY, NOVEMBER 21, 1912—CHICAGO NO. 21

The AUTOMOBILE

British Designers Aim at Increased Motor Efficiency

Parts Lightened by Using Better Materials Giving Greater Economy—Carbureters Improved—Cone Clutch Gaining—Worm Drive Falling Off

Engineers Are Giving More Attention to Accessibility, Silence and the Bodily Comforts of the Passenger—Easy Brake, Oil, Carbureter and Fuel Adjustments Featured

LONDON, Nov. 13—*Special to* THE AUTOMOBILE—British tendencies for the 1913 season as brought out at the Olympia show illustrate the fact that design has become more standardized during the past year than ever before. Almost without exception refinements are minor in detail. A close study of the trend shows that with very few exceptions the makers are confining their efforts to one or two models.

Refinements in materials and workmanship have brought the motors up to a high state of economy. Lighter materials are used for the piston and connecting-rods in some of the cheaper motors. The use of two and three-ring pistons has increased. Passing back to the chassis features it will be seen that the cone clutch is gaining in popularity torque members are fitted with better connections, several makers have abandoned worm drive for the carefully made bevel drive. Worm and sector steering holds its supremity, while front-wheel brakes are on the decline, although one prominent firm has interconnected the front and rear brakes.

British Tendencies Revealed at the Olympia Show

1—An increase of small chassis
2—Decrease in the six-cylinder cars
3—Wire wheels holding their own
4—Cone clutch gaining in popularity
5—Four-speed gearsets on 60 per cent. of cars
6—Sleeve-valve motors have not increased
7—Average horsepower remains the same
8—Worm drive abandoned by some makers
9—Splash oiling used in cheaper motors
10—Front-wheel brakes declining
11—Use of silent chain for magneto drive
12—Underslung rear spring in use
13—50 per cent. of cars have thermo-cooling

Although there is probably less change in motor design this year than in any other previous year as is evidenced by the fact that the average horsepower for both four and six-cylinder cars remains practically the same and the Knight and other sleeve-valve motors have made no prominent advance, a study of some of the more prominent types will be of interest.

The Swift Motor Company, Ltd., Coventry, is confining its attention for 1913 to the output of three new four-cylinder types of the popular R. A. C. ratings, 10.5, 12.0, and 20.1 horsepower. In the new 10 horsepower model, the bore and stroke of which are 65 by 100 millimeters, respectively. The cylinders are formed in a single casting, with the valves on one side, actuated by adjustable tappets, and inclosed by an aluminum cover. The ignition is by magneto only, while on the left-hand side of the engine an oil tank is cast integral with the crank chamber, this oil tank being large enough to hold sufficient oil for 400 or 500 miles. Lubrication is by splash, the feed to the crank chamber being automatic without the use of pumps or any other moving devices. As soon as the level in the crank chamber falls below a certain point, oil automatically starts to feed, stopping when the proper level is reached.

There is a commodious dome for conveying the thermo-syphoned water from the cylinder jacket to the radiator. Above the oil is the exhaust manifold. This takes the form of a ribbed casting having a rectangular section passage. Eight studs hold it upon the cylinder casting. The aluminum door enclosing the valve stems, etc., is a flat plate and assists well in silencing the motor.

The 12-horsepower model which the Swift company introduced during the 1912 season has chiefly been altered in regard to chassis dimensions, that is to say, the tread is wider, the wheelbase longer, while the body itself has been made proportionally larger. The engine has a bore and stroke of 75 millimeters by 110 millimeters, R. A. C. rating, 13.9. The cylinders are cast in pairs mounted on an aluminum crank chamber. The valves are on the left side and thoroughly inclosed. Adjustable tappets with hardened steel rollers are actuated by a chain-driven cam-

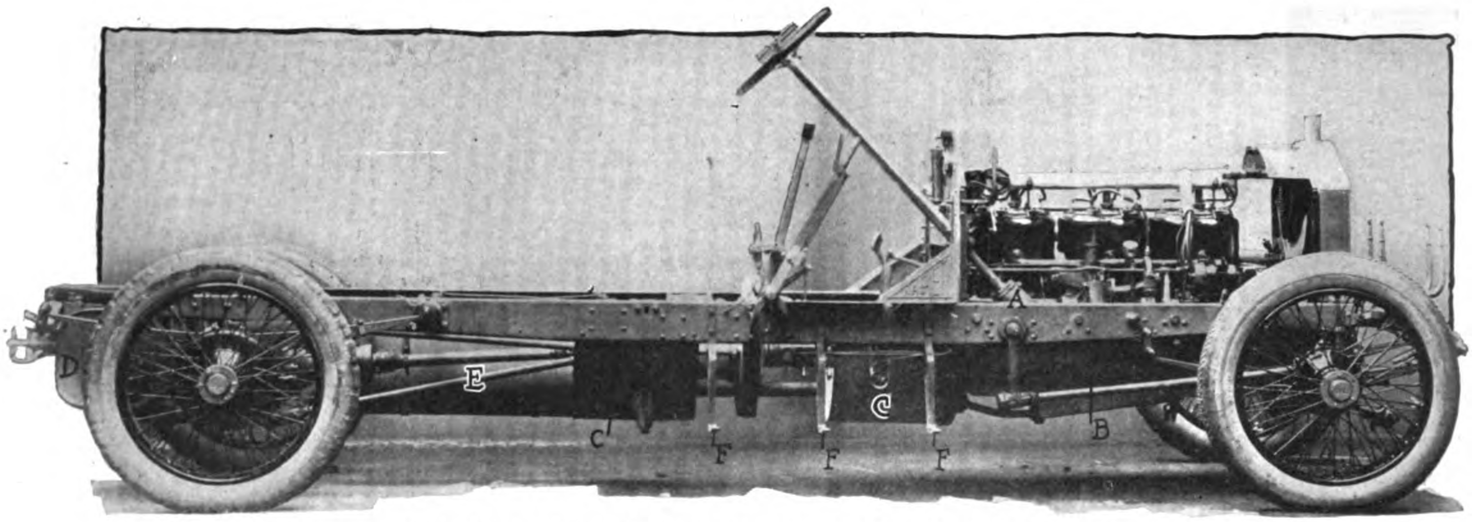

Fig. 1—45-horsepower, six-cylinder Napier chassis. A, steering adjustment; B, reach rod; C, oil pans; F, step hangers; E, torque member

shaft, the chain in question being fitted with a type of adjustment adapted to allow of any back lash being taken up automatically. Ignition is by Bosch high-tension magneto mounted in a very accessible position on the right side of the engine. Cooling is of the thermo-syphon type, the inlet and outlet pipes being of large dimensions and again the cylinders and valve pockets are most generously water-jacketed. Honeycomb type of radiator is supplied, while the fan behind the latter is driven by means of a flat belt off the camshaft.

The means of automatically oiling the engines has been carefully thought out so as to combine reliability with simplicity of detail. The oil is transmitted through the oil sump by means of a centrifugal pump driven vertically from spiral gears off the camshaft and circulated by pressure to the main crankshaft bearings. A by-pass from the delivery pipe is extended to the dashboard where a sight-feed indicates the working of the pump. The oil delivered through the sight-feed above mentioned being then distributed to an oil bath in the timing cover. It should be stated that the timing chain is kept constantly lubricated by running through the oil bath in question. A gauze filter is fitted between the base chamber and sump and an outside pocket is cast to the latter which contains another filter easily detached for cleaning purposes. A gauge cock for indicating the normal level of the oil in crank chamber is supplied.

The Adams Manufacturing Company is confining itself to a single chassis for 1913, the motor of this chassis being of 16-20 horsepower. It has four cylinders 88 millimeters diameter by 120 millimeters stroke, which closely represents average English practice. The cylinders are cast in pairs and the valves are upon one side of the engine. Three bearings only are employed for the crankshaft. The crankpins are 60 millimeters long. A noticeable feature is that no rollers are provided for the tappets, which have, however, a large diameter. The water jackets are very ample providing for the thermo-syphon cooling system. There is a certain amount of water space between the cylinder pairs and the cylinder top ends are spherical and to provide additional strength are ribbed as well. Light detachable doors cover in the valve mechanism.

The oil pump is driven from the same vertical shaft as the air starting distributer. It is placed low and its wheels have wide teeth. Noticeable features are the extra large scoops on the connecting-rods which dip at each crankshaft revolution into the troughs below the cylinders.

Bosch high-tension magneto ignition is in use and the magneto is located at the forward end of the engine close to the air compressor.

The new B. S. A. chassis possesses some points of interest, but confining our attention to the motor, it will be observed that the Daimler-Knight type of engine is employed. The bore is 75 millimeters and the stroke 114 millimeters.

It is of some interest to notice that the cylinders are off-set, a practice that is not very usual with sleeve-valve engines owing to the very low position periodically taken up by the inner sleeve which must consequently be considerably cut away for connecting-rod clearance. In this case it will be noticed that the inner sleeve has a groove to clear the connecting-rod when at extreme angular position, though the cylinders are not more than 12 millimeters out of center.

The pistons which are fairly light have concave tops, which, though perfectly usual in engines of this or similar construction, are objectionable on the grounds of the possible collection of lubricant. The aim of the designer is doubtless to get a spherical or nearly spherical explosive chamber at or shortly after the commencement of the stroke when the temperatures are highest, and there can be no doubt that from a thermal efficiency point of view the aim is a very excellent one.

The trough system of lubrication is in use, the troughs being pivoted

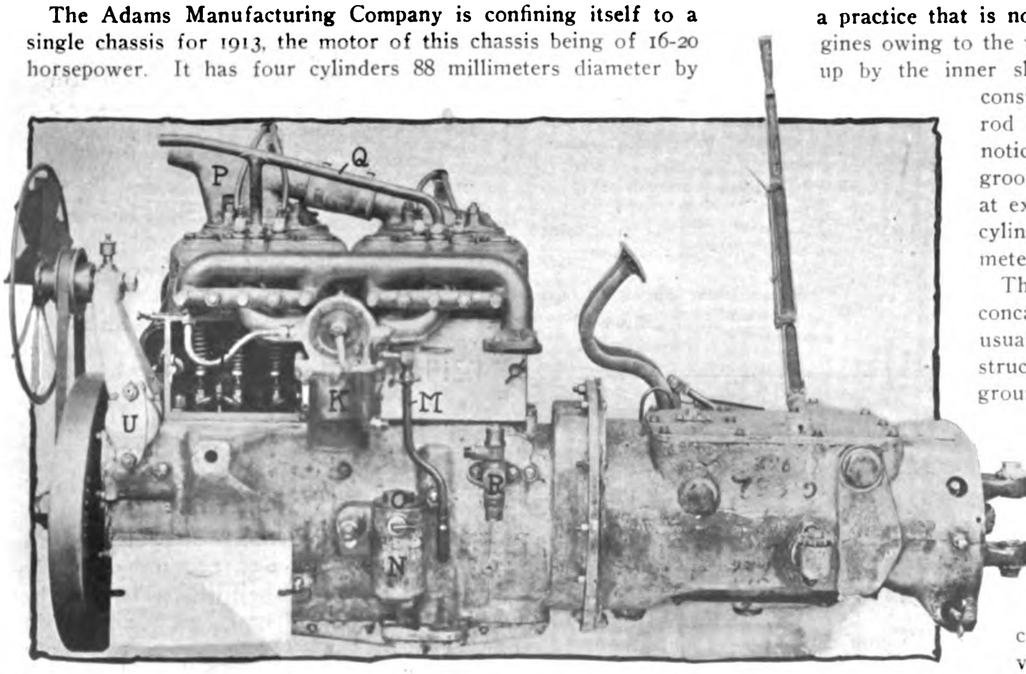

Fig. 2—Napier motor. U, cover plate; K, carbureter; N, O, oil pump; M, oil by-pass; P, Q, water outlets

to the caps of the main bearings and are connected up to the throttle lever so that the oil supply may be in proportion to the work done. A small plunger pump is provided for filling the trough with oil. The plunger has a diameter of 8 millimeters. Immediately behind the pump connecting-rod is a rod which oscillates a small cylindrical valve for mechanically regulating the flow of oil into and out of the pump.

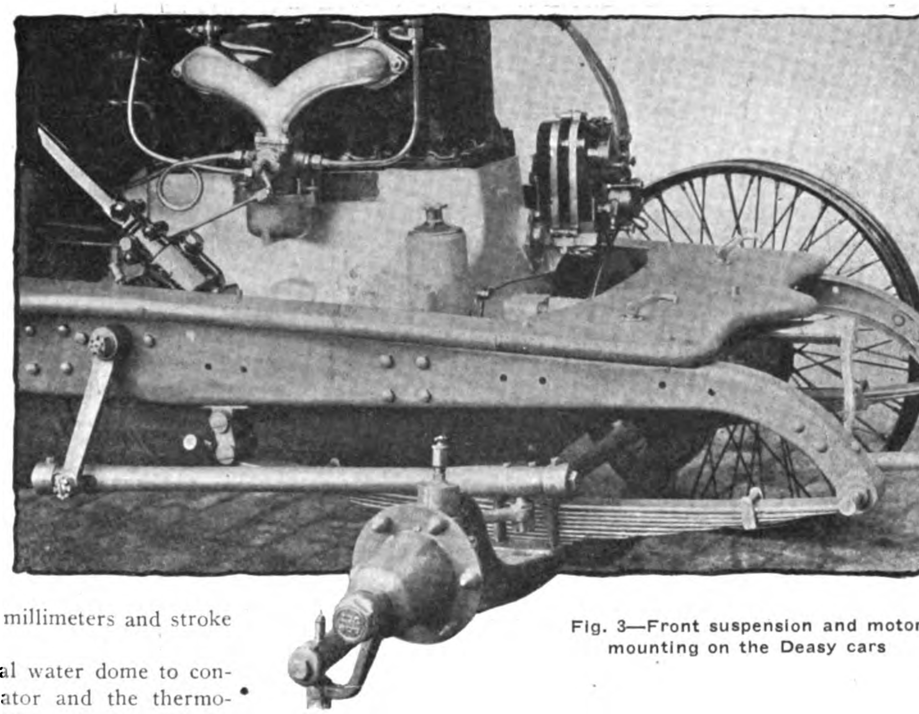

Fig. 3—Front suspension and motor mounting on the Deasy cars

The Belsize 15.9-horsepower motor is an attempt to compete with the American low-priced car. The cylinders are cast en bloc, with ample water jacket between each pair. The casting is, however, very much simplified by the fact that the cylinder heads form another casting which is studded in one piece onto the top of the cylinders. The two castings have their faces machined and copper asbestos washers are interposed. The cylinder dimensions are: diameter 69 millimeters and stroke 130 millimeters.

The cylinder head casting has an integral water dome to conduct the water into the top of the radiator and the thermo-syphon system has been depended upon. The cylinder walls are 6 millimeters thick, and the top of the combustion chamber is 7 millimeters thick and is slightly convex to assist strength.

The pistons are very light and have convex ribbed tops. The length of the piston is 85 millimeters and the lower or skirt part is drilled out to effect a further saving in weight. Two rings only are provided, so that the gudgeon pin can be positioned rather high, and this has the effect of slightly reducing the overall height of the engine. The gudgeon pins have a diameter of 19 millimeters and have 14 millimeter holes drilled through them.

The connecting-rods have a length of 293 millimeters and are very light stampings indeed, the central web being only 3 millimeters thick. The crankshaft journals as well as the crankpins have a diameter of 38 millimeters and the crankpins are 50 millimeters long. The crankshaft journals from the forward end have lengths of 44, 60 and 60 respectively, and the bushes are lined with white metal. The crankwebs have a thickness of 18 and 19 millimeters. Owing to the fact that the cylinders have good water spaces between them and that the crankshaft bearings have a distance between them from bush to bush of only 156 millimeters it has been necessary to overhang the connecting-rod big ends to an extent which is not in accordance with the best practice. The center line of the rod corresponding with the center of thrust pressure is two-sevenths of the crankpin length from one end of the pin—and five-sevenths of course from the other. While a symmetrical bearing is doubtless preferable, it is quite usual to find even twice as much bearing surface on one side of the connecting rod center than the other, but seldom is there so much overhang as that just mentioned. The good length of the connecting rod will to some extent compensate.

Large oil troughs are arranged over the crankshaft bearings, and troughs for the dippers on the connecting rods to draw a supply from. Attention should be drawn to the oil pump; this is of the gear-wheel type and works in a horizontal position at the extreme bottom of the crankcase, and it has a vertical driving shaft which takes its motion from the camshaft. The driving shaft is square at both ends so that the pump can be withdrawn without releasing any coupling bolts or other fastenings. In the center of the tray that supports the connecting rod troughs there is a very commodious filler through which all the oil must pass before it can again enter the pump and be distributed to the troughs. This filler can, moreover, be withdrawn bodily from the bottom of the case or the foul oil may be removed by means of the screw-plug shown. The connecting-rod dippers are large and present a good surface to the oil in

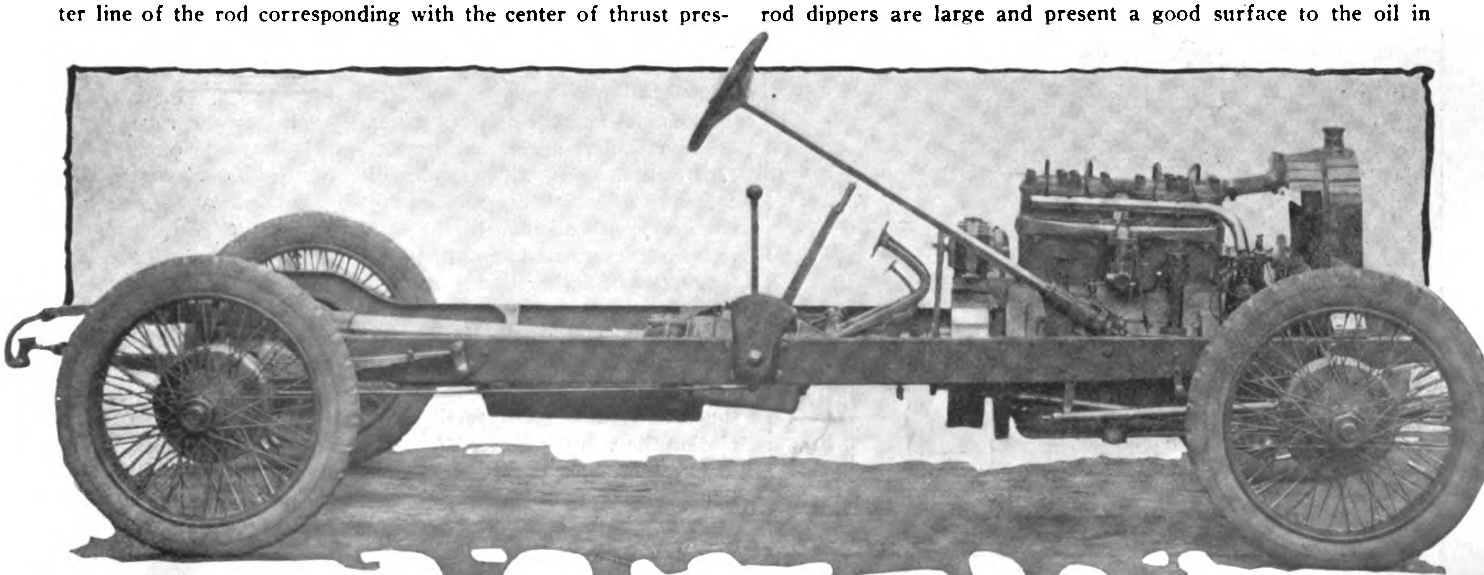

Fig. 4—Chassis of the 25-horsepower Argyle. Note the simple exterior of motor given by sleeve valve construction

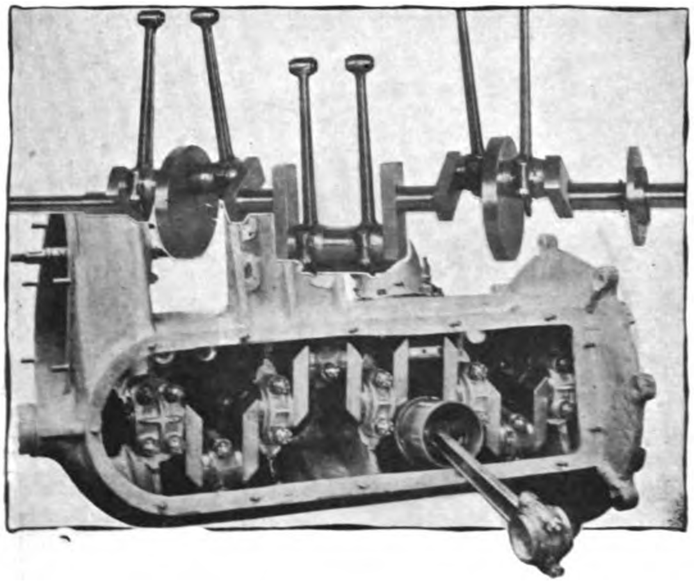

Fig. 5—Six-cylinder crankshaft in use on the Talbot cars and the 15-horsepower Crossley crankcase

the troughs at each revolution, and from the results obtained with the Daimler-Knight adjustable trough system, with its knife-edge dippers, one would expect a great quantity of oil to be thrown up and in view of the fact that the piston skirts are perforated some of this oil may well reach the combustion chamber. It may be for this reason that the ignition plugs are screwed into the valve-caps so that their electrodes lie back in a comparatively deep recess.

The valves, which are all upon one side of the engine, are no more than 28 millimeters in diameter, and this must be considered small at a time when a few good engines have valves with diameters below the seat equal to about half the cylinder diameter. However, there is no doubt that many engines with comparatively small valves do give good power and are capable of running at high speeds. The valve stems have a diameter of 9 millimeters and the guides are long ones.

In discussing the valves the length of the valve springs should be noted. These are, from end to end when in position, nearly, 2.75 inches long. The valve tappets are of very simple construction; there are no rollers, the tappets having merely rounded ends

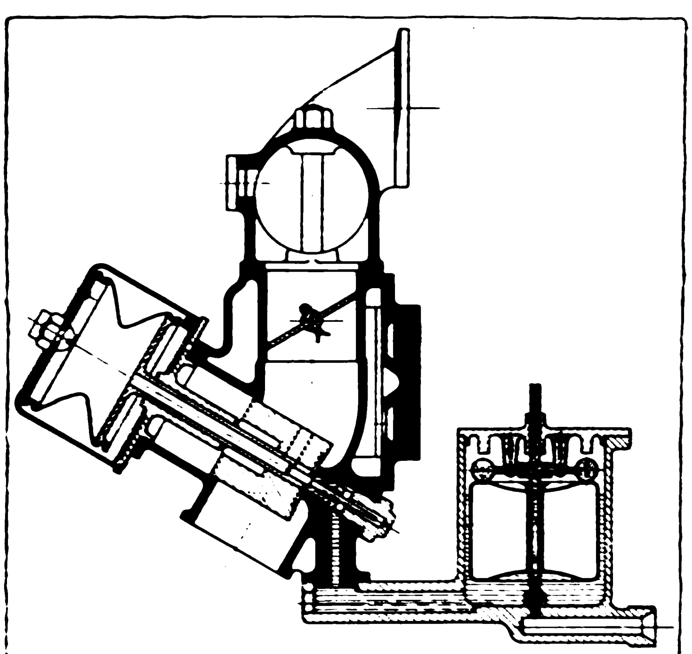

Fig. 6—The C-W. carbureter used on the Wolseley cars. Gasoline connection to the right

and being furnished at the top with hard steel caps. There is perhaps some advantage in the no-roller tappet in that the guide can be brought down very close to the cam—it need, in fact, only just clear the top of the cam—so that there is little bending action on the tappet and a lesser tendency to wear the guide than would otherwise be the case. The length of the tappet guide is 70 millimeters.

The camshaft has a diameter of 19 millimeters and has three bearings, one of which is divided into two, to make place for the chain-drive wheel. The cams are cast solid upon the shaft and have a width of 13 millimeters. It will be gathered from the small width of the chain wheels that they are intended for roller chains in place of the more usual silent pattern chain. The chain wheels are of steel and are solid disks in each case. A small spring-controlled jockey pulley serves to maintain the

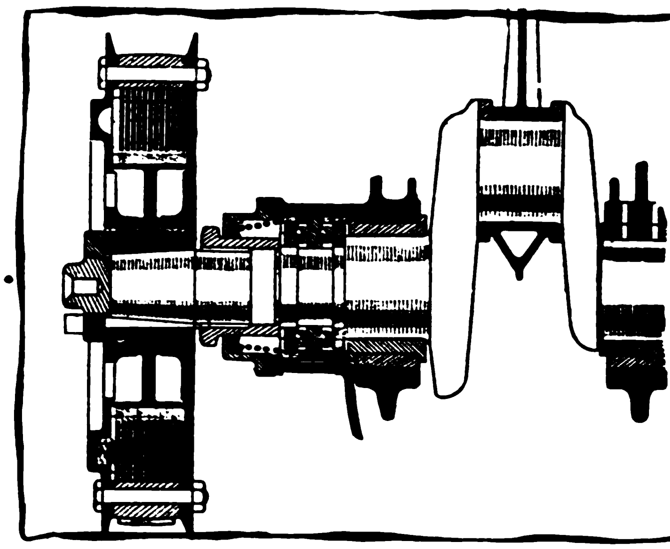

Fig. 7—Lanchester vibration damper to eliminate synchronizing of vibration periods on six-cylinder motors

correct degree of tension. The chain is of course completely enclosed and compares quite favorably with the silent pattern of chain from the point of view of silent running. The valve springs, tappets, etc., are enclosed, light steel metal doors being fitted over them, the doors being held in place by thumb nuts.

The fan runs on ball-journal bearings placed 95 millimeters apart and has a diameter over the blades of 305 millimeters. The exhaust manifold is ribbed and has a jacket to provide warm air from the carbureter.

The carbureter employed is the Claudel-Hobson automatic type, and so economical is the running of the engine with this that 30 miles to the gallon is claimed.

In place of the Darracq 14 horsepower a 16 horsepower has been substituted; the bore and stroke are 85 by 130 millimeters. This model and the 12-horsepower have the rotary valve.

The cylinders are cast monobloc, which is typical of all Darracq constructions, with the exception of the 22 horsepower, the cylinders of which are cast in pairs. The Zenith carbureter is employed with all models, the Darracq company evidently finding it advantageous to fall in with the general system of leaving the matter of carburetion to specialists. The rotary valve (Henriod system) is driven by chain, also the magneto and pump, on the opposite side to the rotary valve.

Probably the point of success in this engine is due to the masking of the valve by the piston. At the top of the stroke the piston entirely covers the port so that at the time of explosion the valve is protected from the effect of combustion. The Darracq firm are evidently quite satisfied with the results obtained during the past year inasmuch as they are applying this valve mechanism to two types. It is claimed that over one hundred parts are discarded by the use of this valve as against the ordinary poppet valve. The rotary distributer is mounted on ball bearings.

Both Humber models have monobloc cylinder castings, and they are very perfect examples of intricate and difficult core work. The inlet and induction pipe are cast together in the form of a cover plate which fastens on to the cylinders with eight studs. These castings also form a water-jacket cover plate.

With the Humber cars careful attention has been paid to lubrication. The pump is situated in the oil sump itself, and is driven by spiral gear from the camshaft, and arranged at the flywheel end of the engine. A conduit is cast in the crankcase from which the oil flows to the main bearings, and the big ends are lubricated through the crankshaft. Instead of the usual pressure gauge an indicator of the plug type is fitted to the dashboard. As long as the plug is projecting from its socket the oil circulation is active.

The Maudslay motor has undergone but little alteration for the coming year. The bore is 90 by 130, and is the only British motor which is fitted with overhead valves. The cylinders are cast in pairs, but united, forming a continuous waterjacket. Both pairs are cast to one pattern. The front end waterjacket coverplate is utilized to carry a bracket within which is formed a bearing for the vertical shaft, and also supports the fan spindle bracket. The vertical shaft is driven from the crankshaft by worm gear which again transmits the motion to the horizontal camshaft over the cylinder by similar gearing.

The camshaft and valve stems are totally enclosed, but free access is obtained to the valves by the cover being hinged, a universal joint applied to the vertical shaft, making it possible to hinge over the cover with the camshaft and its bearings. Between the cover and the valve stems a thrust lever is interposed in which feltpads are so arranged that a film of oil is brought between the cam and the lever. The bearings of the camshaft are provided with ring oilers.

The magneto is driven by means of a chain, and the oil pump is driven from a lower extension of the vertical shaft. The pump is of the rotary type, and forces oil to the main bearings, and thence through the drilled crankshaft.

A feature in connection with the Maudslay engine is that the pistons can be removed through the base chamber, the circular doors being provided for this purpose.

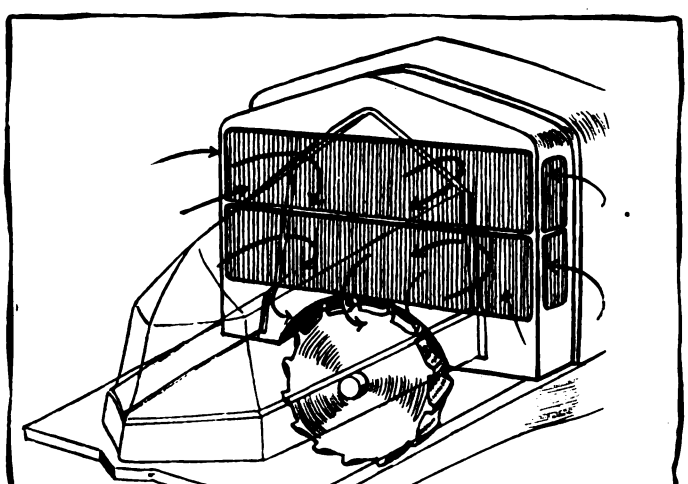

Fig. 9—Diagrammatic view of the cooling system in use on the Deasy cars

The design of the engine readily lends itself to the construction of a six-cylinder, by the addition of another pair bolted to the end flange. The crankshaft has five bearings on the four-cylinder model.

The dimensions of the cylinders on the Bell motor are 3.5625-inch bore by 4.75 stroke. Helical gearing is employed for driving the camshaft, magneto and water pump. All valves are set in line. The crankshaft is set in three bearings, and has a diameter of 1 5-8 inch. The crank bearing at flywheel end is 3.625 inches long, the center bearing 2.625 inches and the starting end 3.125 inches. The pins are 2.125 inches in length.

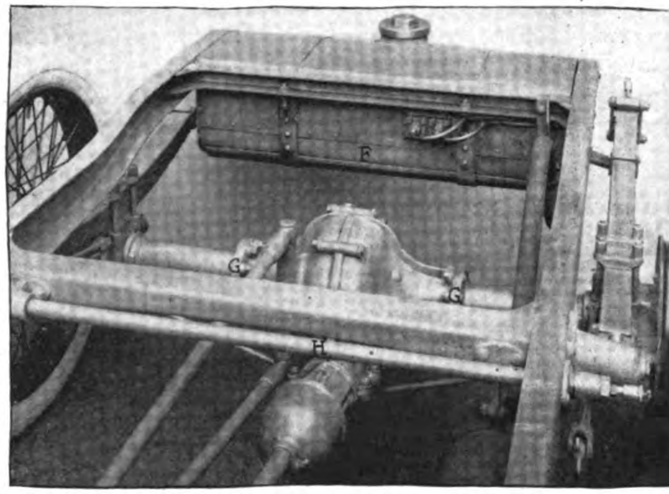

Fig. 8—End view of the Napier 15-horsepower chassis. Note mounting of tank F, crosspiece H and torque connection G

The crankcase is made in three parts. The two main castings are bolted on the center line of the crankshaft, the lower half of the bearing being supported by the lower casting. The third portion of the case forms the bottom and carries the oil troughs and sump.

The lubrication system of the Bell cars is interesting by reason of the arrangement devised for giving a varying amount of oil to the connecting-rods. The rotary oil pump is fixed to the upper half of the base chamber and driven by spiral gear from the camshaft. The oil is first pumped to an indicator on the dashboard, and then feeds the oil continuously to pockets situated over each main bearing, and also to troughs under each connecting-rod. A foot valve is fitted at the end of the suction pipe and a priming fitting to ensure satisfactory working. On the dashboard is fixed a lever working in a quadrant which is coupled to a rod operating a lever coupled to sluice gates fixed to the side of each dripping trough. By operating the lever on the dashboard the sluice gates can be raised or lowered, thus alternating the level of the oil in the troughs. This arrangement is similar to that employed by the Daimler company, except that in the case of the Daimler arrangement the troughs are hinged, and are raised or lowered by a connection to the throttle of the carbureter.

The Vauxhall program comprises two models so far as the main features are concerned, a four-cylinder car having cylinders 90 by 120 millimeters and a six-cylinder car having cylinders of the same dimensions. In the case of the four-cylinder engine the cylinders are cast en bloc. This construction is par-

Equity Rules Hit at Patent Law Abuses

Supreme Court Eliminates Waste of Time in Pleadings and Saves Millions of Dollars to Litigants in Costs by Simplifying Procedure in Chancery so that Comparatively Poor Patentees Can Establish Rights—In Force February 1

PATENT litigation, and in fact recourse to the courts of equity on broader lines, has become so extremely expensive through the cumbersome system in effect that litigants without long purses and the ability to wait have been at a real disadvantage. In fact, the adjudication of many a valuable patent has been abandoned when the patentee learned something of the necessary costs and interminable delays that have been associated with patent litigation. **Therefore, the Supreme Court of the United States has just issued a new set of equity rules that is pronounced by the bar to be the most revolutionary document of the American republic since the Emancipation Proclamation.**

The operation of the new rules will serve to shorten patent litigation fully 50 per cent. on the average and will reduce the costs to a mere fraction of what has been usual. **Under the new rules, according to William A. Redding, chief patent counsel for the Automobile Board of Trade, the great Selden suit could have been disposed of in 6 months instead of 5 years, and that the testimony that filled thirty-six volumes, at a minimum cost of $1 a page for publication alone, could have been contained in one volume.**

The new rules will require more actual ability and much more energy on the part of counsel because of the strict provisions limiting the scope and time for pleadings. Even more important is the rule that requires the bulk of the testimony to be taken in open court under the strict rules of evidence. This rule will eliminate a tremendous amount of irrelevant, incompetent and immaterial testimony.

At the time the final decree in the Dick Mimeograph suit was handed down by the Supreme Court, last summer, THE AUTOMOBILE treated on some of the ideas outlined in the dissenting opinion of Chief Justice White. It was in the form of a symposium specially written by William A. Redding, S. O. Edmonds and John R. Taylor. These gentlemen made certain suggestions about equity procedure in general and specifically pointed at patent practice, and the new rules cover the various points suggested with remarkable accuracy. Of course, they cannot affect procedure in the patent office itself which must be covered by Federal statute, but they do reform court actions along the most radical and progressive lines.

The least fee charged for prosecuting a simple patent suit through the United States District Court is $2,000. From that price the scale runs up to $100,000. As the costs are reckoned with the fee, the saving to litigants under the new rules will be a very material item. The net revenue of counsel will not suffer, for while the attorneys will have to move faster, with the result that they will spend fewer days on a given case, they will have more time to devote to litigation.

Comparatively poor men, owners of valuable patented ideas, will have a better chance to enforce their rights, no matter what the power and wealth of their adversaries.

The new rules are astonishingly brief, numbering eighty-one all told. Patent procedure under them will be reduced, as briefly outlined below. **Upon the actual filing of the bill of complaint, the clerk shall issue the process of subpoena thereon. There is notice contained in the subpoena that the defendant shall file his answer in court, on or before the expiration of 20 days after service. If service is accomplished and the answer is not filed, the complainant is entitled to a decree pro confesso.**

Final decree may be entered at anytime after 30 days subsequent to default.

Save where the existing statutes provide for certain technical forms of pleading, all such technical forms are abolished in equity. As to amendments the rules state that the court, at every stage of the proceedings, must disregard any error or defect in the proceeding which does not affect the substantial rights of the parties.

Exceptions to bills of complaint for scandal, impertinence or redundance are barred but the court upon its own initiative or upon motion may strike out such extraneous matter upon its own terms.

Lack of equity has always been a standard plea where, entirely aside from the facts and law involved, the party advancing that plea wished to be given more time. The usual procedure was to allege that while the opposite party might have an action at law, the facts showed that the suit should have been brought on the law side rather than in equity. The Supreme Court adjusts this difficulty by providing for the peremptory transfer of cases brought in equity that should have been brought in law and orders that only essential changes shall be made in the forms of pleadings and provides that matters ordinarily determinable in law, incident to a suit in equity, shall be determined according to the principles applicable to the case without sending it to the law side of the court.

This might seem to the layman to be an unimportant detail, but the facts of the case are that this rule may prevent delays of as much as a year in a given suit and expenses running into real money.

The form of the bill of complaint is much simplified. The new form will have five sections; the caption; brief statement to give the court jurisdiction; the facts relied upon by the plaintiff, omitting all matters of evidence; exceptions in joinder in the action and a prayer for relief.

Under rule 29, demurrers and pleas are abolished. This means that one of the chief sources of delay in equity is eliminated. All the defenses that are now presented by way of demurrer or plea must be included in the answer instead of being pleaded in succession at intervals of at least 30 days. The effect of the rule will be to make the drafting of bills of complaint much more careful because some technical mistake might lead to the dismissal of the suit by reason of demurrable fault.

The rule provides for hearing of motions to dismiss on the part of the defendant but specifies that if the motion is not successful, answer must be filed in 5 days on pain of a decree pro confesso.

The issue is joined on the defendant's answer, which must be short, omitting matters of evidence. The answer may state as many defenses as are deemed essential, regardless of consistency. General denials must be avoided. Averments except as to value, if not denied shall be deemed confessed.

Matter that heretofore has been used as the basis of cross-bills, must be pleaded in the answer. Unless some counterclaim is set up in the answer, no further pleadings are required. If such counterclaim is alleged, the plaintiff must reply to it within 10 days.

Exceptions for insufficiency of an answer are abolished; thus eliminating another source of delay. Such objections in the future will be handled as part of the suit itself.

The most important change in the rules is the substance of rule 46, which reads:

"In all trials in equity the testimony of witnesses shall be taken orally in open court, except as otherwise provided by statute or these rules. The court shall pass upon the admissibility of all evidence offered as in actions at law. When evidence is offered and excluded, and the party against whom the ruling is made excepts thereto at the time, the court shall take and report so much thereof, or make such statement respecting it, as will clearly show the character of the evidence, the form in which it was offered, the objection made, the ruling and the exception. If the appellate court shall be of the opinion that the evidence should have been admitted, it shall not reverse the decree unless it be clearly of the opinion that material prejudice will result from an affirmance, in which event it shall direct such further steps as justice may require."

Where depositions are allowed in exceptional cases or ordered by statute in patent cases, those of the plaintiff must be filed in 40 days; those of the defense in 20 days more and rebutting depositions within 15 days thereafter. Cross-examinations are ordered to be held in open court where the opposite party desires such a right.

When the time for taking depositions has expired the case goes on the calendar automatically. Postponement of the hearing may be had on application of counsel, but the adjournment of the hearing may not go beyond the end of the trial term.

Save in matters of accounting, reference to masters in chancery shall be the exception and not the rule.

The form of decrees is much shortened and simplified, the Supreme Court ruling that the pleadings, reports of masters and other prior proceedings shall not be recited.

On appeal to the United States Circuit Court of Appeals, the rules require brevity and relevance on pain of having the costs of irrelevant and redundant matter taxed against the party at fault in order to discourage such practice. The rule places the attorneys within its scope and the court is ordered to issue rules against offending members of the bar even when their clients are not held to be amenable.

The old rules of equity are abrogated and the new set effective as of February 1, 1913.

The rule as to the taking of testimony in open court, the omission of printing voluminous records and the simplification of appeal procedure will undoubtedly save millions of dollars a year to litigants.

Under the new rules, the owner of a patent enters suit against an alleged infringer. He files his bill; subpoena issues and service is had. This may occupy a day or a week, rarely the latter. When 20 days have expired the defendant must answer and the suit will be at issue. In patent cases the plaintiff has 40 days to file depositions; the defendant 20 days to answer with another contingent delay of 15 days where rebutting depositions are required. The case is then ready for trial and may be heard within 30 days after the time for filing depositions has expired. **The operation of the new rules would seem to limit a patent action wherein there are no unusual features to 125 days from the time of filing until the trial. In many instances it would appear that cases might be finally heard in 50 days and that 6 months would be about the maximum limit unless something exceptional developed.**

Under the present rules, the answer may be reached in 80 days after the filing of suit, but it may be delayed almost indefinitely by the interposition of dilatory pleas, demurrers and other pleadings upon which issue of the merits of the case can not be joined. The taking of testimony may occupy almost any reasonable amount of time and the rebuttal testimony may still further delay the hearing. The witness to be examined gives his testimony before a master, who has no discretion as to its admissibility. He must transcribe it for the court's use and it becomes a part of the record. As such it is printed at high cost.

The testimony put up to the trial judge is generally an appalling mass. If he is to do his full duty he is obliged to wade through reams of inconsequential stuff. When he has heard the arguments, he must take the briefs of opposing counsel and the testimony of both sides and mull them over until the equity involved becomes clear to his mind.

For that reason alone many cases are reversed in the upper court. There are so many irrelevant documents imposed upon the court and such a terrific mass of conflicting data is developed at the ordinary trial of even the simplest patent litigation that the chance of disordered proportion is always present.

It is almost axiomatic that skillful counsel can delay action in a patent case almost indefinitely, but such will not be the case under the new rules. The limits are clearly defined and in future it will be a remarkable patent case indeed that will linger in the courts pending a hearing for so much as 1 year.

Of course, the new equity rules will not affect the operation of the Patent Office. That must be done by Federal statute. The Oldfield revision of the patent laws died an unmourned death when the late session of Congress adjourned. The measure may be revived next fall, but those nearest to the project are least optimistic.

Unless consideration of it is included in the call that may be issued for an extra session of Congress after President Wilson is inaugurated, it is not likely that the measure will come up until the regular session convenes, if then.

In fact, future action on the subject of revising the patent laws is in the hands of the President's Commission on Economy and Efficiency.

This commission has issued forms containing twenty-four pertinent questions as to prospective changes in the law and all over the country members of the leading associations of lawyers are considering the queries. The New York County Lawyers' Association, which includes many of the leading patent attorneys of the country; the American Bar Association and the aggregations of patent lawyers here and elsewhere have been busy with research work which will probably form the basis of revision when it actually takes place.

Such revolutionary measures as the Oldfield bill are not favored by the majority of the associations. They state that they favor unanimously the enactment of patent laws that will make for speed, certainty and efficiency. The methods by which these three elements shall be joined are the subjects under discussion.

The whole subject of patent law making is extremely technical and patent rights are so firmly founded upon the Constitution that a radical law might have the effect of raising the basic constitutional question every time a patent suit is presented. The careful consideration of proposed laws by the bar associations will probably result in the elimination of a lot of waste, so far as the time of legislators is concerned.

The question of competent examiners; of one or two appeals within the Patent Office itself; of the limitation of the life of a patent to 19 years from the time of filing application; of the whole subject of interferences; of the Constitutional provision awarding exclusive rights to the patentee and the limitation of those rights; the use of unpatented materials and the resale price feature are all subjects of deep interest—too deep, in fact, to run the chance of hasty action by partisan law makers.

U.S. Motor Sale Date Set

Court Orders Property To Be Sold January 8 and Reorganization Plans Have Progressed to Final Form

Grabowsky Power Wagon Company in Receivers' Hands, But No Order of Adjudication Has Been Entered

UNDER decree of the United States District Court, the United States Motor Company will be sold January 8 in New York. Judge Charles M. Hough signed an order to that effect on Monday when the final form of the decree of sale was submitted to him. This form was not substantially different from what was outlined in these columns last week, the changes being of a trifling character.

Under the decree, formal bids for any one or more of the six parcels into which the assets have been divided may be submitted, accompanied by an earnest of good faith in the shape of cash or certified check. The bids thus submitted may be revised upward at the option of the bidder at any time before the closing of the sale at 3 o'clock of the day set.

The action of the creditors appears to be practically unanimous as to the acceptance of the proposed plan of reorganization. On Monday, November 18, 94 per cent. of the claims, based upon the total amount, had been filed with the official depositary, the Central Trust Company. It was announced that at least 4 per cent. more would probably be filed by December 9, which day has been set as a limit for deposit.

This means that of a total of over $11,000,000 of claims, the reorganization committee now has all but $660,000, and has prospects of getting the co-operation of about $450,000 before the expiration of the deposit period.

The Flanders project is reported to be progressing favorably, although no official word of its consummation has been given out. The contract has not been signed but there is a thorough understanding between the parties. This agreement is substantially the contract outlined in these columns last week. The precise details have not been disclosed but it may be said with certainty that the deal is conditioned upon the acceptance of the presidency of the prospective company by Walter E. Flanders as well as the merger of the Flanders company.

It is likely that the situation will be sufficiently developed within 3 weeks to make the official announcement, despite the fact that the date of sale is still 7 weeks in the future.

The deposits of stock are now estimated at over 47 per cent. and according to the prevailing opinion, the total percentage that will come in on the assessement plan will be somewhat more than a majority, considering both issues as a whole.

Oliver Reorganization Consummated

DETROIT, MICH., Nov. 18—All the property of the defunct Oliver Motor Car Company has been purchased from the receiver by a recently organized company known as the Oliver Motor Truck Company. G. A. Meyer is president: F. J. Meyer is treasurer; and R. F. Beach will have charge of the sales. It is the intention of the new company to manufacture the Oliver 1,500-pound light delivery car and the 3,000-pound type, with a few changes made for the betterment of these machines.

Receiver Named for Grabowsky

DETROIT, MICH., Nov. 19—Despite any statements to the contrary the Grabowsky Power Wagon Company has not yet been adjudicated a bankrupt, although a petition recently filed by several of the creditors of the concern in the Federal Court in Detroit will probably result in such action. Judge Tuttle appointed the Federal Trust Company receiver.

It is the intention of the receiver to conduct the business temporarily and in the event the court orders a sale it is hoped that it can be made as a going business. This order may be given the latter part of this week.

Several concerns have shown an interest in the matter and are preparing to make a bid on the business. Rumor has it that the Alco people have an eye on the proposition and in other quarters it is stated that the General Motors Company is also looking it over. It is impossible to verify these reports.

Federal Truck Had a Good Year

DETROIT, MICH., Nov. 16—The Federal Motor Truck Company passed a stock dividend of $100,000 and declared a cash dividend of 10 per cent. on November 14. This company was incorporated 3 years ago for $100,000, and has enjoyed a prosperous business since that time. Its output has increased from fifty trucks during its first year to 135 the second, and 750 for 1912. For the coming season, it is expected that about 1,500 will be sold. The officers of the company are: T. E. Reeder, president; Edwin Denby, vice-president; Garvin Denby, treasurer, and M. L. Pulcher, general manager.

Body Company in Receiver's Hands

LAPORTE, IND., Nov. 18—John C. Richter has been appointed receiver of the Laporte Carriage Company, of this city, giving bond of $10,000. The receiver was appointed in the federal

Automobile Securities Quotations

AUTOMOBILE securities were strong during the past week. Sales were not large because buyers declined to advance bids sufficiently to bring out the stock in material quantities. United States Motor issues were quoted regularly for the first time since the reorganization plan was formulated, although the issues have been dealt in irregularly for some time. The bids were 8 for the common; 32 for the second preferred and 65 for the first preferred. The trading was not brisk. Goodyear was again the spectacular feature of the trading, advancing 12 points on a few bids and making a new high record of 412. Chalmers broke 20 points on two small trades. This stock is very closely held, little of it being on the market, and consequently the usual supporting orders are not present. The table:

court by Judge Albert B. Anderson at Indianapolis. The receivership was created on the application of the Lackawanna Leather Company, of Chicago; the Hackettstown National Bank, of New Jersey, and M. M. Kates, of Chicago.

In addition to the application for a receiver a petition was filed asking that the carriage company be declared a bankrupt. The company manufactures automobile bodies and buggies. According to the complaint the company became embarrassed by losing a large contract it had with the Mitchell Motor Company. It was pointed out in court that the company's profits in 1910 aggregated $28,000, but in 1911 it lost $15,000 and up to the present time in 1912 its losses have been $35,000.

—

Henry Hess Sells to D. W. F. Company

Announcement has just been made that the D. W. F. Ball Bearing Company, of Germany, has purchased the interests of Henry Hess in the Hess-Bright Company, of Philadelphia. Mr. Bright will continue with the company and will direct its policy. He has been elected president. The new secretary of the concern will be A. T. Bruegel and the treasurer, C. L. McCalla.

The Hess-Bright Company has been the American representative of the D. W. F. concern for a long time, importing the German bearings and manufacturing a number of domestic products.

The sale indicates still closer relations with the American trade by the German manufacturers, but is in nowise a revolutionary move. The interests have been closely allied in the past. The domestic manufacturing program has not been announced.

Market Changes for the Week

THE past week saw quite a few changes. The chief topic in the crude rubber trade on Tuesday was the auction sale of plantation rubber in London. This went off at higher prices, fine up-river Para closing at $1.07 per pound, a gain of $.03. The market for linseed oil was easy owing to the decline of late in seed at Duluth, where prices again weakened on Tuesday, closing at $.52, a loss of $.06. Lard oil increased $.06; petroleum, Pennsylvania, crude, rose $.10, while cottonseed oil also rose $.16. Tin lost $.02, owing to poor trade, and lead also experienced a decline, closing at $4.60 for a loss of $.15. Antimony remained at $.09 1-4 until Tuesday, when it dropped $.00 1-4. Beams and channels, Bessemer steel and open-hearth steel remained constant throughout the week.

Nash G. M. President

Buick Executive Succeeds Thomas Neal as Head of Giant Company—Latter To Be Chief of the Board of Finance

Neal's Administration Remarkably Successful in Rehabilitating Property and Establishing Firm Footing

DETROIT, MICH., Nov. 19—Thomas Neal, who for the past 2 years has been president of the General Motors Company, has relinquished that office and will become chairman of the board of directors. C. W. Nash, manager of the Buick plant and one of the vice-presidents of the company, will succeed Mr. Neal as president. Mr. Neal's retirement is in accordance with an understanding at the time he took office.

In the fall of 1910, according to a statement given out by the company today, when the concern was re-financed and the executive offices moved from New York to Detroit, the financial interests supporting the company realized the necessity of securing as president a man of very broad business experience, capable not only of exercising the abilities of an organizer and the judgment of an experienced manufacturer, but also of inspiring confidence among investors and financiers. Mr. Neal was urged to take the office and accepted with some hesitancy. Although he was attracted by the great possibilities offered to one interested in large business enterprises, his acceptance necessitated close application to executive work at a time when he was desirous of being rid of such burdens.

Mr. Neal took the office with the understanding that he would be permitted to retire as soon as the business was re-established on a satisfactory basis. The financial report of the company recently issued to stockholders shows that this time is ripe and that the business is in splendid financial condition with a net earning of 17 per cent. on the common stock during the last year.

—

At the meeting of the stockholders of the General Motors Company held Tuesday in Jersey City all the old directors were re-elected, save in the case of J. N. Wallace, who retired and was succeeded by Charles W. Nash. The annual report as already published in these columns was presented. The board will meet again to choose officers for the coming year.

The directorate consists of the following: Joseph Boyer, Anthony N. Brady, Emery W. Clark, W. C. Durant, Andrew H. Green, Jr., J. H. McClement, Edwin D. Metcalf, M. J. Murphy, C. W. Nash, Thomas Neal, James J. Storrow, Albert Strauss, Nicholas L. Tilney and Jacob Wertheim.

The board contains the same representatives of the financial interests that took hold of the company after 1910.

Charles W. Nash was elected president of the corporation at the subsequent meeting of the directors.

Mr. Nash succeeded W. C. Durant as general manager of the Buick after the reorganization and will continue in that special capacity. Thomas Neal, retiring president, will remain on the board and will continue as head of the finance committee.

The various changes signify that the affairs of General Motors are progressing regularly and that the pressing need for a financial and industrial specialist at its head has abated. Mr. Neal made a wonderful success of his administration. Mr. Nash is a manufacturer of pre-eminent rank and is highly regarded as an executive.

W. C. Durant, who was re-elected to the board was not present at the meeting as he had been called to Detroit on business connected with his new manufacturing project. The attendance at the meeting of the stockholders was small in numbers but represented practically all of the capital stock issues.

Ward Heads King Co.

Buyer of Plant Is Chosen President—Bayerline, Bollinger, Chase and Day Are Members of His Staff

Freight Car Shortage Situation Improves as Peak of the Load Approaches—Only 1200 Increase

DETROIT, MICH., Nov. 16—Following the visit of Artemus Ward to this city to look over his new property, the King Motor Car Company, which he purchased for $40,000, it is announced that the reorganized concern will be a close corporation, all of its stock to be held by Mr. Ward and those actively engaged with him in the enterprise.

Artemus Ward, Jr., son of the new owner of the King company, will spend much of his time here. His father is to be president of the company. The personnel of the concern in addition to Mr. Ward is: J. G. Bayerline, manager; T. A. Bollinger, factory manager; T. P. Chase, engineer; J. B. Siegfried, purchasing agent; W. L. Daly, sales manager; J. Mohardt, superintendent; F. A. Vollbrecht, chief accountant and Geo. Gurney, manager service department.

The present line of four-cylinder cars will be continued, in addition to which another model will soon be placed on the market to sell at a figure close to $1,200. This latter machine is really the one which Mr. Bayerline, who was formerly connected with the Warren Motor Car Company, built last summer. It was designed by Mr. Chase under direction of Mr. Bayerline.

The new King company has shipped forty-three cars since it was taken over 5 weeks ago by Mr. Ward. A production of about three cars a day is now being maintained. A show room will be opened at the factory on Jefferson avenue within a short time.

Frontier Company's Annual Report

BUFFALO, N. Y., Nov. 18—At the annual meeting held here Friday of the stockholders of the Frontier Tire & Rubber Company, officers were elected for the ensuing year. Orson E. Yeager being chosen president, while Frank V. E. Bardel and John W. Gibbs were chosen first and second vice-presidents respectively. George T. Roberts was elected treasurer, while M. F. Dirnberger, Jr., was elected secretary with A. R. Robertson as assistant secretary and treasurer. W. R. Price was selected as general manager for the coming year. During the past 6 months the business of the Frontier Tire & Rubber Company was reported to have increased 140 per cent. About $600,000 worth of business already has been closed up for next year according to the report.

Freight Car Shortage Less Severe

Net shortage of automobile freight cars only increased about 1,200 during the fortnightly period just reported by the American Railway Association which ended November 7. The total net shortage at that time was 51,259. Compared with what was predicted, this is a smaller shortage than expected by at least 8,000 cars and indicates that the peak of the load is being passed right now. The next report covering the period ending November 21 is expected to show a decrease to about 40,000 cars net shortage and by the first report in December the traffic men believe that there will be demand for only about 20,000 more cars than can be supplied. By the second report in December the operating departments of the roads will probably have a few idle cars over and above the full quota in use.

The reduction of the shortage in coal cars represents most of the improvement in the situation so far as the grain from the Northwest is moving in still larger volume than heretofore. It has been shown that fully 100,000,000 bushels of grain in excess of the shipments of 1911 up to this time has been moved to primary markets. The visible supply of wheat alone is placed at 22,000,000 bushels, a record that will stand for a few days anyway. Reckoning 1,000 bushels to the car, the extra grain shipments so far this year have been 100,000 cars. As a matter of fact, the average car will not carry 1,000 bushels, so the actual excess total is even larger.

There has been little congestion, considering the immense volume of freight handled, as the weather has been good for shipping all over the land.

Compared with last year, when there was a net surplus of freight cars totalling 26,514, present conditions indicate an increase of freight for shipment of about 79,000 cars.

Among the railroads that placed rush orders for cars last week were the Northwestern, Omaha, Lackawanna and Ontario and Western. The orders amount to 3,000 cars. The total number of cars ordered during the week is estimated at 13,400, while about 30,000 are included in inquiries made by the Pennsylvania. New York Central lines and smaller systems, orders for which have not been placed as yet.

The grain movement of the past week was about double that of last year for the corresponding period.

Warren Creditors Extend Notes

DETROIT, MICH., Nov. 20—(*Special Telegram*)—At the request of the directors of the Warren Motor Car Company, creditors and officers of the company held a joint conference at the Pontchartrain hotel on November 19, at which it was decided to extend all notes and other obligations until about June 1. The creditors were unanimous in their opinion that the Warren company is in healthy enough condition to continue business. On November 12 another joint meeting was held at which the exact condition of the company's affairs was gone over.

The liquid assets are about $375,000, under the new arrangements, while liabilities total $350,000, of which $50,000 is a stationary liability against the plant, leaving sufficient margin for conducting business.

Although the plant has not been operated at its full capacity of late, it is expected that within 2 weeks it will be turning out its maximum output again.

Cars to take care of 2 months' business are ready for shipment at once, while the entire 1913 output of 1,500 machines have been sold, which will take care of the business up to July 1 of next year. The various models will be continued as planned.

At yesterday's meeting six were added to the directorate from among the creditors, which number added to the present officers will bring the board up to nine. The enlarged board is made up as follows: Harry Bassett, Weston Mott Company; H. J. Mallory, Weston Mott Company; F. H. Lewis, Lewis Spring and Axle Company; M. R. Jencks, Port Huron Engine Company; J. W. Mowe, Firthstone Tire & Rubber Company; G. Jahn, Bosch Magneto Company; Homer Warren, C. R. Wilson and C. H. Wilson.

On Thursday afternoon, November 21, a meeting of the directors will be held at which the resignation of several of the present officers will be accepted and new ones elected.

Postmaster Prepares for Parcels Post

Postmaster Morgan, of New York, is preparing his department for the prospective rush of mail matter under the new parcels post law which goes into effect January 1. The parcels business is handled at present by the express companies and with the transference of this business to the postoffice vast additions to the present transportation facilities of the departments will be required.

Just how much it will amount to is a matter of guesswork and the department will probably await the event itself before entering into hard and fast contracts for transportation. The package mail during the holidays is always large even at the present high rates of postage, and Mr. Morgan intends to try out the parcels system beforehand by handling the Christmas parcels. The method to be used will be to hire automobile trucks and horse-drawn wagons for the occasion.

The aggregate mail under the parcels post law probably will not be much larger than it was last year, during the first few weeks of the law's operation, but any increase will be felt almost instantly in New York and the department figures that an accurate gauge of the situation can be had from noting local conditions.

The general department has not yet contracted for automobile trucks to be used in the outlying sections where it is expected that the new law will make rural deliveries much more laborious than they have been in the past.

The bids asked by the government to furnish certain types of automobile trucks specified several sizes that would be useful for this purpose, but, on the surface at least, the specifications were not aimed at mail delivery cars.

Finger Prints on Drivers' Licenses

BUFFALO, N. Y., Nov. 18—Superintendent of Police, Regan, of Buffalo, is heartily in favor of the plan recently outlined by State Secretary Lazansky, of recording finger prints of all chauffeurs and automobile owners to prevent gangsters and gunmen from securing licenses. "Of course, many owners might object to giving their finger prints," said Chief Regan, "but after the advantage of the plan is shown I believe the majority would be willing." There are no two finger prints alike while many faces look so similar that identification is difficult.

Bathtub Case as Limit to Patents

WASHINGTON, D. C., Nov. 18—A decision of the Supreme Court of the United States which marks an epoch in connection with efforts to violate the Sherman anti-trust law by concealing the violation behind the patent laws of the country, handed down on Monday, in the "Bathtub" case from the United States District Court of Maryland, was a victory for the government throughout. The opinion, which was delivered by Justice McKenna, was unanimous. The government, in originating the case, attacked the enameled ware manufacturers on the grounds that the fifty defendants named had entered into a combination to restrain interstate trade in sanitary enameled ironware, and had attempted to monopolize that trade. The prosecution was based on an agreement between the defendants and Edwin L. Wayman, who had patented a dredger, a tool employed to sprinkle enamel over the red hot iron ware, which agreement, it was alleged, constituted an illegal agreement.

The lower court held that the agreement destroyed competition and fixed prices in violation of the Sherman law, and, furthermore, that the patent on the dredger did not make the agreements lawful. Justice McKenna said the combination of the manufacturers became effective through Wayman's plan to grant license on his patent. The agreements clearly therefore he continued, "transcended what was necessary to protect the use of the patent or the monopoly which the law conferred upon it. They passed to the purpose and accomplished a restraint of trade condemned by the Sherman law. The added element of the patent in the case at bar cannot confer immunity."

Justice McKenna said there was nothing in the "mimeograph case" of last year which contravened the views he was expressing. He said:

"Rights conferred by patents are indeed very definite and extensive, but they do not give any more than other rights to universal license against positive prohibitions. The Sherman law is a limitation of rights which may be pushed to evil consequences and therefore restrained."

A. C. A. Must Pay Debt

U. S. Supreme Court Holds That Unregistered-Corporation Defense Is Not Valid in Lupton Suit

Opinion Gives Jurisdiction to Federal Courts Even Where It Is Specifically Denied Under Statute

THE status of the foreign corporation which fails to register under the laws of the State of New York has been further outlined by the recent decision of the United States Supreme Court in the suit of D. Lupton Sons & Company against the Automobile Club of America for damages under a contract by the former to funish a large bill of goods and labor to the club. This consisted of metal window frames and other merchandise and the labor necessary to install the material.

The matter was tried in the United States District Court before a master, who decided that the complaint was not duly founded because the Lupton company was a Pennsylvania corporation which had not complied with the New York statute providing for registration with the Secretary of State.

The matter was then taken to the United States Supreme Court on revision, and that court reversed the finding of the master, sending the cause back to the district court with a mandate to enter a judgment in favor of the complainant for about $3,000.

The constitutionality of the whole statute was not covered by the opinion, but the rule was sufficiently outlined so that it has been established that while the statute is valid and in effect within the jurisdiction of the state courts it has no force in the Federal tribunals. While it is optional with a foreign corporation whether it shall prosecute a suit in the state of Federal courts, the rules of Federal procedure provide that the United States courts shall not take jurisdiction of any matter in which lass than $2,000 is involved. Thus, if the foreign corporation, unregistered in New York, wishes to enforce a claim of less than $2,000 it is powerless to do so. If it is over $2,000 it may do so in the Federal courts. Of course, if the corporation is registered it can proceed under the jurisdiction of the state courts. Scott, Upton & Newcomb argued the matter for the Luptons.

Court Again Defines Joy-Riding

MILWAUKEE, WIS., Nov. 18—A point of law was established in a case tried at Milwaukee last week which will make it possible to collect damages from the persons or person responsible for taking a car without the owner's consent for joy-riding or other purposes. The W. E. Allen Company, state agent for the McFarlan and Marathon, brought suit against Robert Leonard and five others for damages due to the misuse of a car. Leonard was employed in the Allen garage and took out a touring car, a demonstrator, and invited five friends to go riding, and in the early hours of the morning landed the car against a pole.

Allen's attorneys proceeded against both driver and passengers on the ground that concerted use was made of the car and that all were guilty of conversion. Not only was claim made for repair cost, but for depreciation of the car's value brought about by such repairs.

The court decided that the driver alone could be held liable, excusing the four defendants who were passengers. However, the fifth passenger, who did not appear at the trial and was not represented by counsel, was held jointly responsible for this error of omission, with the driver. Judgment was rendered against both. Had the fifth defendant appeared he would have been excused from liability.

Atlanta's Show Opens

Prospects Promise Well with Cotton High and Plentiful and Finances of South in Fine Shape

Machine Tools To Be a Feature of the New York Automobile Show—Boston Electric Club Reorganized

ATLANTA, GA., Nov. 16—The Atlanta show, third in the Gate City of the South, and the second under dealers' auspices, was opened tonight. Thirty-two branches and agencies are exhibiting cars and accessories. The exhibit was divided as follows: gasoline pleasure cars, seventy-eight; electrics, seven; commercial cars, six; polished chassis, four; accessory exhibits, eight; oil exhibits, one and motorcycles, five.

Considerably more space was available than last year 30,000 square feet as against 18,080. This increase of space in the local Auditorium-Armory was accomplished by raising the floor to the level of the stage, by tearing out the wings of the stage and by utilizing to the fullest extent the space under the seat banks.

The showing of automobiles is comprehensive and representative. Fifteen of the most important automobile manufacturers in America are represented in Atlanta with branches and as many more are represented by agents, with the result that the Atlanta show each year usually offers a good assortment of standard cars.

The cars are better displayed than usual this year. The tendency to overcrowding has been avoided and the display is excellent.

Atlanta's position in the South is shown by the number of factory representatives who are here for the show. Included in the list are the following notables: H. O. Smith, president Premier Motor Manufacturing Company; C. P. Henderson, president Henderson Motor Company; Jas. G. Haislet, chief engineer, Studebaker Corporation; Leo A. Peil, general sales manager, Mitchell Motor Car Company; E. W. Morse, sales manager Hudson Company; J. H. Newmark, advertising manager, Oakland Company; Guy Monahan, advertising manager, Premier Motor Manufacturing Company; W. C. Leslie, general manager Firestone-Columbus; Henry Haven, assistant sales manager, Flanders Electric; R. W. Chapman, assistant sales manager, National Motor Vehicle Company; H. C. Beavers, assistant to the president, Stevens-Duryea; R. H. Collins, general sales manager, Buick Motor Company; James T. Roach, sales manager, Locomobile Company, of America; W. J. Slater, assistant sales manager, Michigan; in addition to practically every southern division manager in the field.

Little can be told of the volume of business which will be transacted during the show, but there is every reason why it should be large. The South is most prosperous this fall—and in that respect a different Dixie from last fall, when pauper prices for cotton put the entire section to the bad. This year cotton is plentiful, the price is vastly higher than a year ago and in every respect there is ample reason why Southerners should have money. Unless the opinion of the show optimists is wrong, more cars will be sold this year at the show than at both previous shows put together.

Machine Tools at National Show

Machine tools will be featured at the coming national automobile show in New York, special emphasis being laid on commercial vehicle week, when the intense crowding of pleasure car week has passed. The Automobile Board of Trade conferred last week with the National Machine Tool Builders' Association and an agreement was reached.

The Society of Automobile Engineers favors the addition of machine tools to the big show and according to the plans now being formed the examination of the prospective exhibits by members of that organization will be one of the attractions of the annual meeting's program.

Secretary M. L. Downs is now in Cleveland arranging some of the essentials of the added attraction. According to tentative plans the machine tool exhibit will be housed in the Palace and efforts are being made to have it as complete as possible, considering the comparatively short time that remains between now and show time.

The show will be the first ever given by this section of the industry and as the national show always brings together the cream of the mechanical staffs of the various automobile factories, its importance to the manufacturers is great.

Without giving out any definite data it has been announced that the total exhibits already signed up for the New York show during both weeks is 9 per cent. greater by number than actually showed in both buildings last year.

Boston Electric Club Reorganized

BOSTON, MASS., Nov. 18—Boston electric automobile dealers and allied interests changed the name of their organization from the Electric Vehicle Club of Boston to the Electric Motor Car Club, of Boston, at a meeting held at the Hotel Marliave, November 14. The committee on reorganizing through its chairman, F. J. Stone, reported a new constitution and by-laws which were adopted after discussion.

The principal feature of the new constitution is the division of membership into three classes, namely:

Those who derive an income resulting from the sale of electric automobiles and accessories.

Private owners and operators and their representatives.

Representatives of the trade or daily journals.

The constitution also provides a financial basis for making the club self-supporting. Provision is made for the appointment of standing and working committees to advance the interests of the organization.

Following the evening's business, John A. Voodry delivered an address on "Salesmanship" in which he outlined his opinions of the cardinal points in selling electric cars. F. D. Stidham spoke of the need of a complete list of charging stations for the Boston territory.

The advisory committee of the club was directed to confer with representatives of the Bay State A. A., Massachusetts A. C. and other bodies of motorists relative to the present stringent enforcement of the ordinances regarding the leaving of cars on public streets. It was suggested that a petition of motor car owners be prepared for presentation to the proper authorities to protest against these regulations.

The officers of the reorganized club are as follows: President, Day Baker; vice-president, E. S. Mansfield; secretary, H. F. Thomson; treasurer, J. S. Codman.

Savannah Negotiating for Races

With regard to the reports originating in Savannah, Ga., that application will be made for the 1913 running of the Vanderbilt Cup and Grand Prize road races, William K. Vanderbilt, Jr., of the Motor Cups Holding Company, has announced that nothing definite has been decided about the running of the races.

The terms proposed by the Savannah Automobile Club contemplates full entry lists for both events as a condition precedent to accepting them. Under the tentative plan suggested, the club asks for half the net proceeds, the rest going to the military organizations that guard the course.

RICHMOND, VA., Nov. 16—The Richmond Automobile Club has completed arrangements for 2 days' racing meet to be held at the State Fair Grounds on November 29-30, following the Virginia-Carolina football game on Thanksgiving Day.

Foreign Cloth In Discard

American Makers of Trimmings and Upholstery Coverings Now Rival Product of French and German Factories

Minor Details of Workmanship Still To Be Perfected at Home Before Supremacy Is Established

THE American car buyer has every reason to feel gratified that he is now able to obtain direct from manufacturers in this country quite what he desires of medium priced upholstery goods for his car. And should the manufacture of automobile cloth and laces continue to progress during the next few years as it has unmistakably progressed during the past 5 years **there will be scarcely any class of upholstery fabrics which cannot be obtained from the American manufacturer, except perhaps the trimming designed for an exclusive line of limousines.**

Not a few domestic manufacturers are now supplying the market with automobile upholstery fabrics of a particularly varied line which in tastefulness and real elegance of effect fairly rival the most popular French designs.

American cloth manufacturers and lace producers are working in cordial co-operation in an effort to equal, if not to surpass, the product of the foreign manufacturer. These home manufacturers expect to show—indeed, they are even now showing—samples of cloth and lace harmonious and luxurious in design and effect. In this matter, up to a comparatively recent period, the foreign manufacturer has been clearly in the lead of his American competitor. **No longer need we to look to the French and German cloth and lace makers' products for those seemingly matchless cloth and lace effects.** The manufacturers of our own country are now producing cloths and laces which in design and quality, and in those other fine points of distinction, are nothing short of what the European manufacturer is able to bring forth.

What the American car, when upholstered, chiefly fails in is the proper proportion of upholstery design, in those infinite minor details of workmanship, and in the variety, extent and quality of the essential furnishings.

The Paris samples of upholstery workmanship bear the stamp of an artistic touch combined with a thorough appreciation of all the little niceties, both of workmanship and material, which enter into the finished car. In this respect, and only in this respect, do the Frenchmen excel the artificers and designers on this side of the Atlantic. Practically every French craftsman is a master in arranging and providing for the pleasure and comfort of the car occupants in the matter of interior conveniences ordinarily overlooked by the American artisan. This is a part of automobile construction and finish that the craftsmen in this country must be permitted by their employers to learn fully.

But, after all, these are minor issues compared with the supreme one of providing a car interior furnished with cloth and laces, and a style and design of upholstering, sufficient to meet the demands of the most fastidious traveler.

The French cloth and lace makers were first to introduce the practice of matching laces with standard colors of cloth. This method of making fabrics enabled the carriage and automobile manufacturer to decide upon any color of cloth and feel assured that he could easily obtain a lace to harmonize with it. Upon this side of the water no such method of manufacture prevailed, and as a result the vehicle manufacturer was put to great disadvantage.

The French manufacturer, moreover, was the first to introduce the sample book system as it is known today.

At one time the impression prevailed that the superiority of the French manufacturer's products was due to the fact that Australian long fiber wool was principally employed in the making of cloth and lace fabrics, whereas in this country only the short fibered wool was used, and, as a matter of fact, continues to be used. However, experience has taught a different lesson and today both the long and the short fibered fleece are being used with equal success.

We now have in this country manufacturing plants devoted to cloth and lace making of much larger and more imposing proportions than any to be found abroad. The American car manufacturer and owner have cause for satisfaction in this condition of a great industry inasmuch as it provides a fine selection of fabrics to choose from at a cost less than what one might expect to pay for the same grade of goods with a foreign label attached.

At the approaching Madison Square Garden Automobile Show, as perhaps never before, the public will have an opportunity to judge of the variety and magnificence of upholstery fabrics as made up in a great display of cars of both medium and high-priced design. And it may be suggested that the prospective buyer go over the cloths and laces made up into beautiful works of art, and study at close hand, and for himself, what creations of luxury they afford.

Paint and finish and upholstering are both selling and buying factors, and they are at the present time figuring more largely in the sales department than ever before. Sales are known to rise and fall by these issues alone.

Among the novelties in finish applied to automobile body work for exhibition at the Madison Square Garden Show is **the cane or basket-work effect brought up under a very high state of finish.** This basket-work imitation comes in the form of paper with a muslin back, the cane or basket-work imitation being stamped out on this. The material is imported, coming in rolls 20 inches by 80 inches. The fabric is cut to fit the panels, these panels being painted in any desired shade or color. The material is pasted securely to the surface and over it is then placed the high finish.

At the coming New York shows novelties in lake pigments will be displayed to an extent hitherto quite unknown. An automobile body with two or three shades of lake graduated from light to dark constitutes a daring exhibition of color work, and when well done never fails to elicit admiration. For example, in the treatment of scarlet lake, starting at the top of the panel with the deepest shade, the color is then graduated in gently softened tones until the light shade is reached, with the result that when the blending is artistically executed the effect is something splendid to see.

All the lakes running along through from rose lake, crimson lake, carmine lake, Munich lake, English scarlet lake, and purple lake, to chatemuc lake, are susceptible to the magic of brush work to an extent perhaps greater than any other colors, and this doubtless explains their increasing popularity in automobile work. On the wide and flowing fields of the big cars these pigments of rare beauty and brilliancy are made to display their real magnificence and serve the pleasure of delighted car owners the world over.

Lakes Call for High-Class Process

Generally speaking, it doesn't pay to cheapen the process of developing the lake or transpartnet color finish. A purple or crimson lake that costs $6 a pound should be brought to the surface by a strictly high-class process, or not at all. To use expensive lake pigments over cheap, inadequate grounds, by cheap methods, is only an ill devised method of throing money away. For cheap, inexpensive methods stick to the solid colors.—From *The Carriage Monthly* for November.

Principal Types of Thermometers and Pyrometers Briefly Explained with Reference to Their Best Ranges of Temperature and Their Value in the Manufacture of Automobiles and Accessories—New Tendency in Meter Implements

THERMOMETERS and Optical Pyrometers—Rapid and accurate determination of temperatures plays such an important part in the manufacture of automobiles that the measuring instruments used for this purpose more and more crave the attention of manufacturers wherever quality of the output and economy in production are considered equally indispensable. In the quenching bath of water or oil the desirable temperatures range from 0 to 200 degrees C., according to circumstances. For the drying room, the color-baking ovens and for the temper colors the required heats range up to 400 degrees; in the annealing ovens from 300 to 690; at the forge and in gas or oil furnaces from about 600 to 1100 degrees C.; and for electric or oxy-acetylene welding much higher. In all cases the exact temperature is of greater or lesser importance for obtaining the best possible results. The steel industry, the electric furnace and the automobile are probably the factors in modern industrial life which are most directly responsible for the rapid progress which has been made of late years in developing practical measuring instruments from scientific laboratory apparatus. One of the most important of all the advance steps, however, has been evolved, in the form of optical pyrometers, by a scientific combination of the common blacksmith's method of judging heat by colors with the no less common practice of judging colors by matching them.

The development which has taken place has gone in several directions. Old-style thermometers have been perfected so as to give readings from minus 200 deg. C. to plus 750 degrees and to record the readings. Electric-resistance thermometers cover the range from minus 200 degrees to plus 900 degrees, while of especial industrial convenience from 300 to 600 degrees. Thermo-electric thermometers, which are frequently termed pyrometers, are especially useful from 700 to 1000 degrees. By combining the electric-resistance and the thermo-electric types, readings from minus 100 to plus 1,000 degrees may be reliably recorded. The optical or sight pyrometers are particularly adapted for measuring temperatures above 1,000 degrees and up to 7,000 degrees, although special constructions in this class of instruments cover a more limited range. It is by means of the optical pyrometer that the temperature of the sun, as seen through a clear atmosphere, has been recorded as about 6,000 degrees.

During all this progress the means for establishing and correcting a heat scale has nevertheless remained unchanged. The old gas thermometer, which is described in nearly every textbook on physics, is still the highest authority by reference to which the dials of all other instruments are verified. In its first form it was based on the expansion of air, but now hydrogen is the gas used for measuring temperatures from minus 200 degrees up to plus 1,000 degrees, and the receptacle which is exposed to heat or cold is of platinum. At higher temperatures hydrogen shows an inconvenient tendency to pass through a large number of substances, platinum included, and nitrogen is used instead. The bulb or receptacle for the gas which until lately was made of refractory procelain is now blown from molten quartz. Richard *Frères* and Wiborgh have turned out thermometers of this type intended for industrial uses, but they have not found wide application.

IMPROVEMENTS IN OLD TYPES

Glass thermometers depending upon the expansion of a liquid, such as mercury, alcohol, toluene, spirit of gasoline or pentane, have been limited to small ranges of temperature by the freezing and boiling points of the fluids and by the softening of glass under a relatively moderate heat. By replacing the air over a mercury column by nitrogen or carbonic gas and using Iena glass, in which borates are added to the silicates, the range can be raised to 550 degrees C., but there is still the need of guarding against sudden changes and mechanical shock. Siebert & Kühn, of Cassel, have lately made thermometers of quartz which can be used up to 700 deg. C. and, being provided with a scale traced on a strip of quartz, these instruments are reliable even with prolonged exposure to the heat and they are completely indifferent, mechanically, to sudden changes. But at 700 degrees the inert gas over the mercury column reaches a pressure of 60 atmospheres, and the mechanical fragility remains an undesirable feature.

More robust thermometers depending upon the expansion of a fluid are made by Richard *Frères*, Steinle & Hartung, C. J. Eckardt and others. The type is shown digrammatically in Fig. 1. The steel bulb *a* is connected by a capillary tube *b*, whose outside diameter is 5 millimeters and inside diameter 0.5 millimeter, to a hollow and flat spring *c* whose cross-section is shown at *d*. The air is driven out (presumably by mercury vapor), and the apparatus is filled with mercury through a small hole afterwards closed with solder. Now, when bulb *a* is heated, mercury is driven into the hollow spring *c* which is thereby extended, so as to assume a shape giving more room for the mercury, and its free end is made to move the hand *e* over the graduated scale *f*. These thermometers are used for locomotives, being in that case equipped with a compensating device which is practically a duplicate hollow spring in which the mercury is actuated from the same bulb and acts upon the same dial axis, thereby quieting the hand and obviating the disturbing effects of wind, speed and vibrations. Similar thermometers are provided with electric sound signals indicating desired maximum and minimum temperatures.

The recording of temperatures is usually accomplished by a stylus tracing a curve on a roll of paper which turns around once in 24 hours and may be set to turn at different speeds if desired. The Eckardt system for this purpose is indicated in Fig. 2. A flat disk may be used instead of a roll, and photographic methods of recording have also been employed.

To transmit the readings at a distance—the office of a technical manager, for example—electric connections are established operating a second indicator hand at the distant place of observation, either continuously or intermittently; or, if it is only desired that the temperature may be ascertained at any chosen time, a press-button system is arranged. These devices are expensive, however, and are disappearing because the transmission of readings at a distance, wherever it is essential, justifies the installation of electric-resistance or thermo-electric thermometers by means of which it may be accomplished much more conveniently, since the electric or thermo-electric current is with them the direct means for measuring the heat variations.

INDISPENSABLE FOR ANNEALING WORK

The electric-resistance method is used especially in England, where it was first perfected through the research work of Callendar. Between the limits of minus 200 deg. C. and plus 700 deg. C. the thermometer of this type seems to be more sensitive than the Le Chatelier thermo-electric pyrometer, while the latter excels above 700 degrees. For temperatures between 300 and 600 degrees it is in practice an indispensable guide, as this range is not covered well by other types. It is based on the fact that the electric resistance of a metallic conductor grows about 4/1,000 for each degree of increased heat, in the case of pure metals. Once introduced in industrial form upon the European continent by William Siemens, several models of this type have been manufactured. The latest are those made by Hartmann & Braun, of Frankfurt, and by Heraeus, of Hanau. The active part is a platinum wire coiled upon a quartz core 3 to 4 millimeters in diameter and 60 millimeters long. The coil is inserted in the slightly larger bore of a very thin quartz tube. The air is then expelled while the external tube is softened in an oxy-hydric flame until the platinum wire becomes completely imbedded in quartz. By a somewhat elaborate method, too long to describe, the resistance of the platinum wire is made exactly 50 ohms at 0 deg. C., and this feature is alike for all thermometers of this kind. The element produced in this manner corresponds to the mercury bulb of an ordinary thermometer, and in continuation of it there is a quartz sheath containing the transmission wires which are of silver, gold or platinum. The whole of this is then enclosed in a steel tube for protection against mechanical and chemical actions. As electric source, either a storage battery or a light current with a suitable auto-converter may be used.

In order to measure the variable resistance, which gives the temperature, there is used a post comprising a Wheatstone bridge and an Arsonval galvanometer (as made by Siemens & Halske) with a graduated scale. The resistance of the three branches I, II and III of the bridge (Fig. 3) is equal to that of the thermometer at zero of the thermometric scale; at this temperature it passes no current. If the temperature varies, and thereby the resistance, the hand of the galvanometer is deflected. A simple reading gives at once the temperature. The essential condition for getting an exact measurement is that the resistance of the bridge remains constant. To control and, if need be, regulate this factor, a variable resistance A is used which may be modified at will. By switching in the control resistance P by means of commutator C the hand should at a certain temperature take a certain position marked in red on the dial. If the hand covers this mark the apparatus is in order. Otherwise the variable resistance A is changed until this result is obtained.

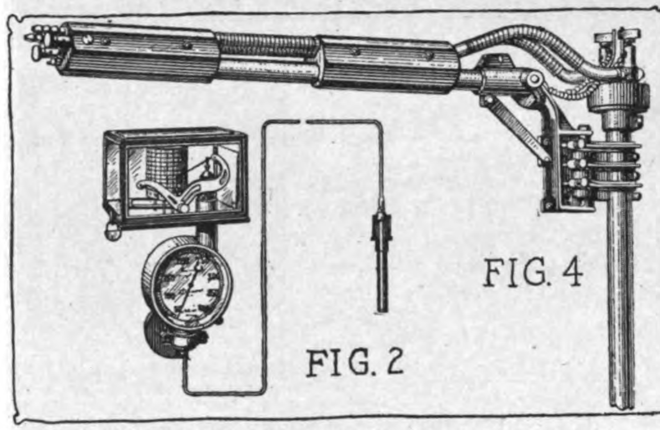

FIG. 4

FIG. 2

Fig. 2—Recording with steel bulb mercury thermometers
Fig. 4—Thermo-electric pyrometer with water-cooled terminals

The control may also be effected by switching in a voltmeter between the two conduits connecting the battery and the Wheatstone bridge, and afterwards the resistance A. By the control resistance P, which is equal to that of the thermometer at a certain temperature, the tension of the current is verified, as before, and it is corrected, if necessary, by varying A. A simple reading of the galvanometer then gives the temperature. This method is especially advisable where many thermometers are controlled and read by means of a single galvanometer.

WIDELY PREFERRED FOR HEAT TREATMENT OF STEEL

Becquerel first conceived the thermo-electric instrument, and the industrial form given it by Le Chatelier is widely known. Though its price is high—about $80 in France—the Heraeus firm alone has made and sold 2,000 of its kind. The thermo-electric element comprises a platinum wire, 1 1-2 meters long and 0.6 millimeter in diameter, fused by an oxy-hydric flame to another wire of the same dimensions but composed of 90 parts of platinum and 10 parts of rhodium. Insulation is provided by porcelain tubes, and the whole is placed inside of a steel tube, if the temperatures to be determined range below 1,000 deg. C.; otherwise in a sheath of quartz glass or fire clay.

The tension of the thermo-electric current which is produced when the element is placed in the fire is a function of the difference in temperature at and around the element and at the terminals of the apparatus. The current is transmitted to a galvanometer with two scales, one giving the electromotive force in millivolts and the other the temperature. The calibration is done by comparison with a gas thermometer. The means for registering the readings at a distance are well known and simple, consisting in mechanical provisions for causing an indicator point to travel over an inked or smoked paper roll or disk. By means of different-colored inks the readings from 6 pyrometers may be recorded on one roll.

For temperatures lower than 800 deg. C. and with a view to reducing the cost of the thermo-electric element, Keiser & Schmidt, of Berlin, and Hartmann & Braun, of Frankfurt, use iron and copper-nickel or silver and copper-nickel instead of platinum and platinum-rhodium, and the indications furnished by these instruments are sufficiently accurate for ordinary purposes, while their lower price permits the installation of more thermometers at any one plant.

It is a drawback to thermo-electric thermometers that they must be exposed somewhat long to the heat which is to be measured before reaching an equilibrium of temperature. The time can be shortened by baring the element to the heat, but

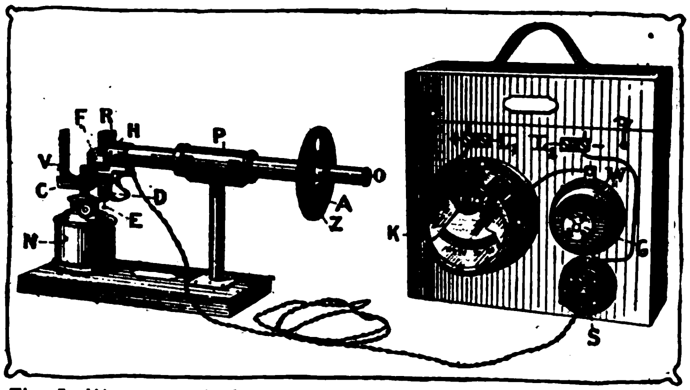

Fig. 5—Wanner optical pyrometer arranged with auxiliary lamp N for verifying or correcting its readings

when this is done the platinum easily becomes brittle. As the thermo-electric apparatus measure only the difference of temperature between the element and the terminals and are calibrated for a certain temperature of these terminals—usually 20 deg. C.—it is necessary for accuracy to keep the terminals cool by a water circulation, as in the Le Chatelier pyrometer shown in Fig. 4, or else to displace the graduate scale of the galvanometer by means of an adjustment screw to compensate for the discrepancy between 20 degrees and the actual temperature of the terminals. Some instrument makers who use an iron and copper-nickel element, notably Keiser & Schmidt, add a compensating device, which is practically a prolongation of the element and renders it unnecessary to make any correction of the terminal temperature. With this construction it is also practicable to use the instrument for the middle range of temperatures, such as, for example, for telling the heat of superheated steam.

INSTRUMENTS DEPENDING ON HEAT RADIATION OR LIGHT RAYS

Féry's pyrometric telescope was the first industrial application of Stefan's scientific experiments of 1880, subsequently confirmed by Boltzman and others. Féry's instrument is based on the law that: The amount of heat radiated by a black body (as defined by Kirchhoff) or from an opening in a furnace at high temperature is proportional to the fourth power of the absolute temperature of the black body or of the furnace.

The heat radiations from the heated piece act on an iron and copper-nickel element, and the current produced is measured by a galvanometer. The recording may be done as with a Le Chatelier instrument. The advantage of the pyrometric telescope, as of the optical pyrometers which are replacing it in industrial practice, is that it permits the determination of heat at a distance without necessity for exposing either the instrument or the observer to its ordinary effects.

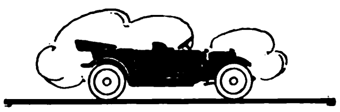
Optical pyrometers are distinguished from the Féry instrument by being based on the measurement of light and not on that of radiated heat. They therefore serve for the measure of temperature only when this is so high that light is emitted. As visible light rays from metals begin at 500 deg. C., the optical pyrometer method becomes practicable only from 600 degrees up and preferably should not be used until 900 degrees is reached. The principle of all optical pyrometers is to match the light emitted from the object whose temperature is sought with another light whose temperature value is known. The best-known pyrometers of this type are the Le Chatelier pyrometric telescope, the Mesuri & Noel, the Holborn & Kurlbaum, the Moise and the Féry & Millochau. To calibrate these instruments it is necessary to know the law of relations between the intensity of light emitted by the heated material and its temperature. These laws have been studied by Paschen, Wanner, Lummer and Pringsheim and have been mathematically established by Wien and Planck. It is on the basis of the work of these men that Mr. Wanner has constructed an optical pyrometer—manufactured by B. Hase at Hannover—which certainly at the present moment is the one most extensively used in Germany and which now begins to be employed in France also.

The Wanner pyrometer is a telescope of about 0.30 meter in length which in its interior contains a spectroscope combined with a photometer. By means of two slits situated in a vertical plane, within the telescope, two bundles of light rays are directed. One comes from the incandescent body whose temperature is to be determined; the other from a little incandescent lamp which serves as a means for comparison. The rays first pass through a prism where they are decomposed by refraction, then through a Nicol polarizer of Iceland spar and, before reaching the ocular, through a Nicol analyzer.

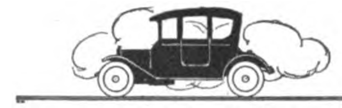
The instrument is so constructed that the observer receives only the red light corresponding to a wave length of 656 millimeters (the red line C in the spectrum of hydrogene). What he sees is two red spots of different light value. The lower one corresponds to the temperature to be measured and the upper one to that of the electric control lamp. The Nicol analyzer is now turned until the two spots are equally luminous. A wheel, Z in Fig. 5, with a graduated scale A measures the angle which the analyzer must be turned in order to produce this result, and Messrs. Wien and Planck have established the law by which the temperature is obtained as a function of the sine of this angle. It is important that the light source is of constant intensity, and as the source actually is a storage battery it is necessary to determine the resistance to be placed between it and the electric bulb—whose location is inferiorly at H in Fig. 5. This is done by means of a lamp burning acetate of amylic alcohol giving a fixed intensity of light to which the electric bulb light is made to correspond. Fig. 5 shows the apparatus as arranged for making this control. L_1, L_2 are the terminals of the battery, W the resistance rheostat adjustable by the button G. K is the galvanometer indicating the constancy of the light current, S the contacts, P the pyrometric telescope, N the control lamp in position for comparing the two lights, VFR the visor for placing this lamp correctly, EDC the contacts for the electric lamp, O the ocular. When all the precautions are taken, the results from this pyrometer are satisfactory, but its price is high, running from $150 to $200 in Germany. Though apparatus of this order date back only to 1902 nearly a thousand of these instruments have been sold, mostly to steel producers. They are made in several models, for heats ranging from 840 deg. C. to respectively 2,000, 4,000 and 7,000 degrees, and in some of the models the temperature may be read directly from a scale while with others one or more tabulations must be consulted. Recently a model has been made which measures heats as low as 600 degrees, and in this all the luminous rays—not only the red ones—can be gathered into the luminous spots which are compared.—From article by Eugène Grandmougin, Professor of Chemistry at Mulhouse, in *Le Génie Civil*, September 7 and 14. [Popular "pyroscopes" have also appeared in the German market in which the heat colors of steel are reproduced by a kerosene flame and differently colored films. These are turned into view until the heat color of the work is matched, and a scale then shows the temperature.—Ed.]

MOTOR Implements—It is noticed from accounts of public tests of motor-powered agricultural machinery recently held in France that the blades and wire tools used for cutting and loosening the soil in the machines made by the *Motoculture Française* company are not now so thin and resilient as first planned by Mr. de Meyenburg, who is identified with this company and was the first to conceive and realize the need for elastic soil cutters and the abandonment of the traditional ploughshare. In the new machines the cutting tools have some resiliency, but most of their ability to avoid breakage and violent shocks to the whole mechanism of the machine, when stones or other obstructions in the soil are encountered, is obtained by mounting them on springs which permit the cutting tool in its entirety to be deflected from the obstruction.—From illustrations in foreign exchanges.

Two Closed Bodies for Overland 59-R



Coupé Design and Special Collapsible Top Adapted for Runabout Chassis



By George G. Mercer

A SUITABLE car to which a closed body can be adapted is the Overland 1912 model 59-R. Two designs are presented here for this purpose, one a new body of coupé form and the other a combination body or roustabout.

Of the two alternatives the coupé body would cost approximately $800, no alteration being necessary on the chassis, while the second design, which is really an addition to the body, and one, moreover, that easily permits of a return to the original runabout form, requires an outlay of only $300.

The stock Overland 59-R runabout is shown in Fig. 4 and the general appearance of the coupé and roustabout adaptations is given in Figs. 5 and 7.

The coupé body is a light-weight design suitable for the small chassis of this car, the wheelbase of which is 106 inches, the tires being 32 by 3.5 inches; the springs, 1.75 inches, and the four-cylinder motor 4 by 4.5 inches. It is installed in exactly the same space lengthwise as that occupied by its predecessor and the increase in weight over the runabout body will not exceed 400 pounds.

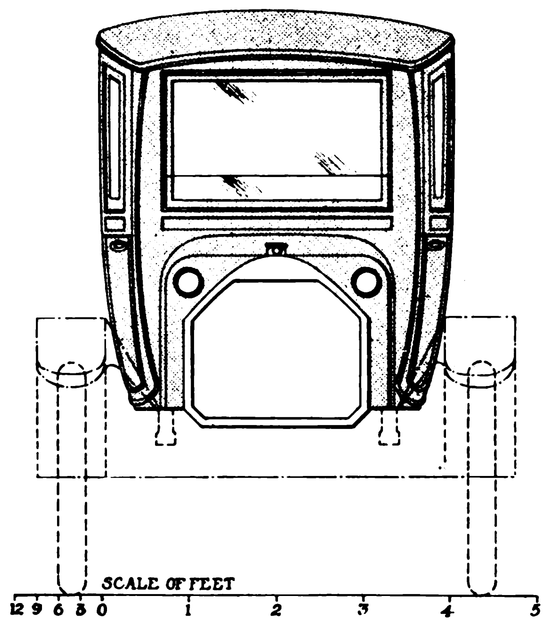


Fig. 1—Front view of Overland coupé design

No new parts, such as mud guards, etc., are required, with the single exception of the dash lamps, and these are included in the body specifications. The rear tire carriers remain on the tool box as with the runabout design.

Though the suggested body is small in its plan dimensions, the height over the cushion to the roof is of standard measurement, and the size of the cushion being the same as that of the runabout there is ample accommodation for two people. The size of the door opening and length and width of the body are given in Figs. 2, 3 and 5. As overloading the chassis is a point of some importance in small cars of the type in question, the construction work is of light design, the greatest saving of weight being effected by forming the upper rear quarter and the back panel of cloth instead of the usual wood or metal paneling.

The cloth used is heavy enameled duck, finished with a surface that imitates the grain of leather. This material is capable of withstanding hard wear and when used in the manner shown is impervious to water. A single piece is used, extending from the hinge pillar on one side to the corresponding pillar on the opposite side. It is fastened under small metal mouldings at the front and along the bottom edge, and at the top it is fastened under the wood drip moulding. The framing inside to support the roof and to form the openings for the windows is of very light construction. An oval window is inserted in each side and two smaller windows of circular form at the rear. All are finished with metal mouldings that serve to fasten the cloth and also to form a flange to hold the glass.

Although the sides of the body are made of flexible material, the roof does not fold down, but is a permanent structure of .25-inch pine sheathing. Over this is stretched the same material as that used for the panels, but of lighter weight, and the edges are nailed under the drip moulding also.

Ordinary practice is followed throughout the remainder of the body construction. The lower panels and the cowl are

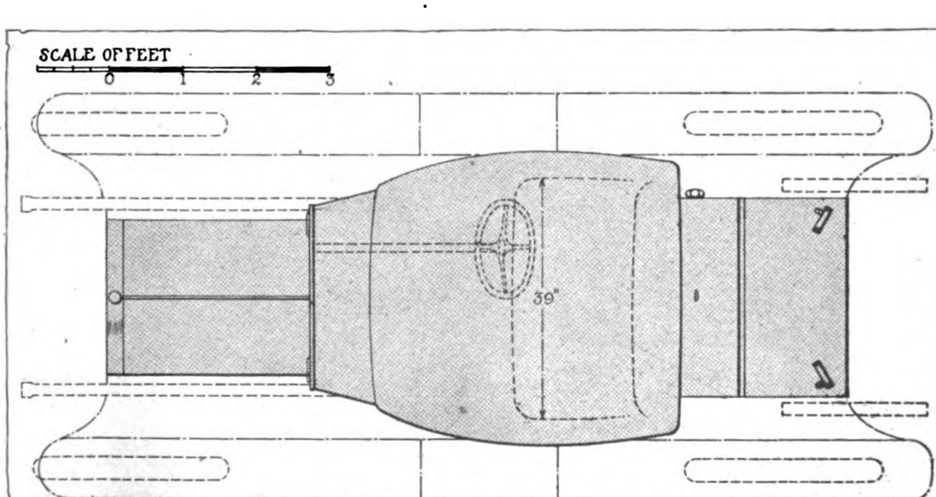

Fig. 2—Plan of suggested Overland coupé

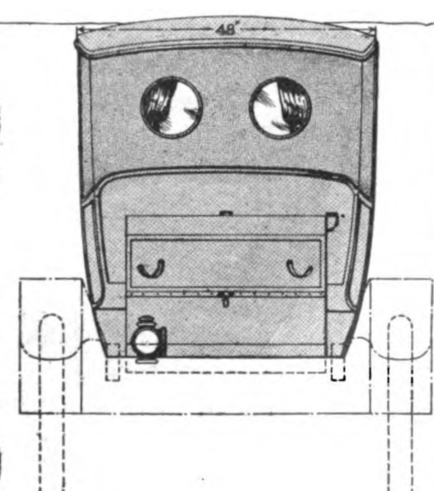

Fig. 3—Rear view of Overland coupé

.0625-inch aluminum, with aluminum mouldings; the door handles and locks are of the regular pattern, and outside butt hinges are used on the doors to save weight in the framing.

Mahogany frames are used for the door windows and these are made to drop their full length. The frames of the front windshield are of the same wood and the cut in the shield for the visor is shown in Figs. 1 and 5. The oval side panes and the circular rear lights are stationary, and all glass used is plain crystal plate.

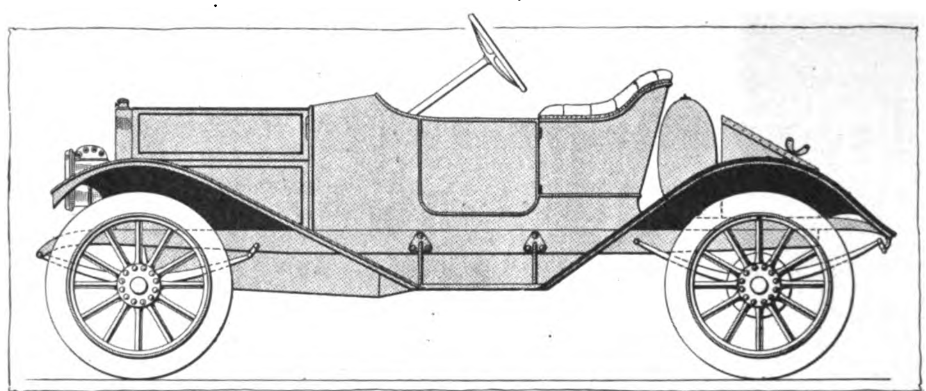

Fig. 4—Side view of standard Overland 1912 model 59-R

Suitable colors for painting the body would be the standard blue used on Overland cars for the cowl and body panels below the belt line, with black mouldings. This will agree with the chassis color. Above the belt line all framing and mouldings could be black to correspond with the black enameled cloth used for the side and back panels and the roof. The name panel on the doors to be blue and the metal mouldings around the quarter and rear lights for fastening the cloth on the edges to be black, also the door hinges.

The finish on the door handles, supports for the front windshield, exposed rim of the dash lamp and both the tail and headlights to be either silver or nickel.

For the trimming a suggestion that would harmonize well with the design would be blue broadcloth of a lighter shade than the body color, with lace of the same ground color and having a fleck of red woven into the pattern. The light touch of red will give warmth to the interior appearance and this can be further advanced by having the carpet similarly marked. The trimming of the body will be the same as if the exterior panels were of metal or wood. The blue silk curtains on the doors run on spring rollers, while those on the quarter and rear windows are draped.

Suitable appointments for the interior would be one card case and one ash tray with blue morocco finish fastened to the doors; an electric roof dome light, and possibly some form of corded hat rack. These and a few pockets suitably distributed will be all that are required.

The dash lamps are let into the dash with only the rim and the glass visible. The horn is located on the right side and is preferably of the electric type. The steering wheel is located on the right side and the change gear and brake levers in the center of the car, allowing easy access from either side. This construction also makes possible the use of a narrower body than usual. Cloth panel material will lessen considerably the cost of the article, and the body as designed, finished according to the description given above and mounted on the chassis will represent an outlay of approximately $800.

This design is very compact and for the purpose for which it is intended it will be found well adapted to meet all requirements.

To turn now to the roustabout design, Fig. 7 shows the same standard body as illustrated in Fig. 4, but with the addition of a closed-in top of waterproof cloth on rather novel lines. This top is provided with two large glass windows on each side, one on each door and another in each quarter back of the door. It is light and flexible and affords ample protection when raised with the glass frames in position. When lowered, as indicated in Fig. 6, it affords all the advantages of an open car. The windshield is stationary and is of the V-type, that is, it consists of two planes receding at a slight angle from a center pillar on the cowl. By this construction the wind-resisting surface is lessened, as the slanting sides deflect the air pressure instead of fronting it as is the case with the ordinary flat windshield. This form of construction also has the merit of imparting considerable strength and rigidity to the forward structure.

The top as a whole is quickly and easily manufactured and is designed so that it can be removed in the spring and the body

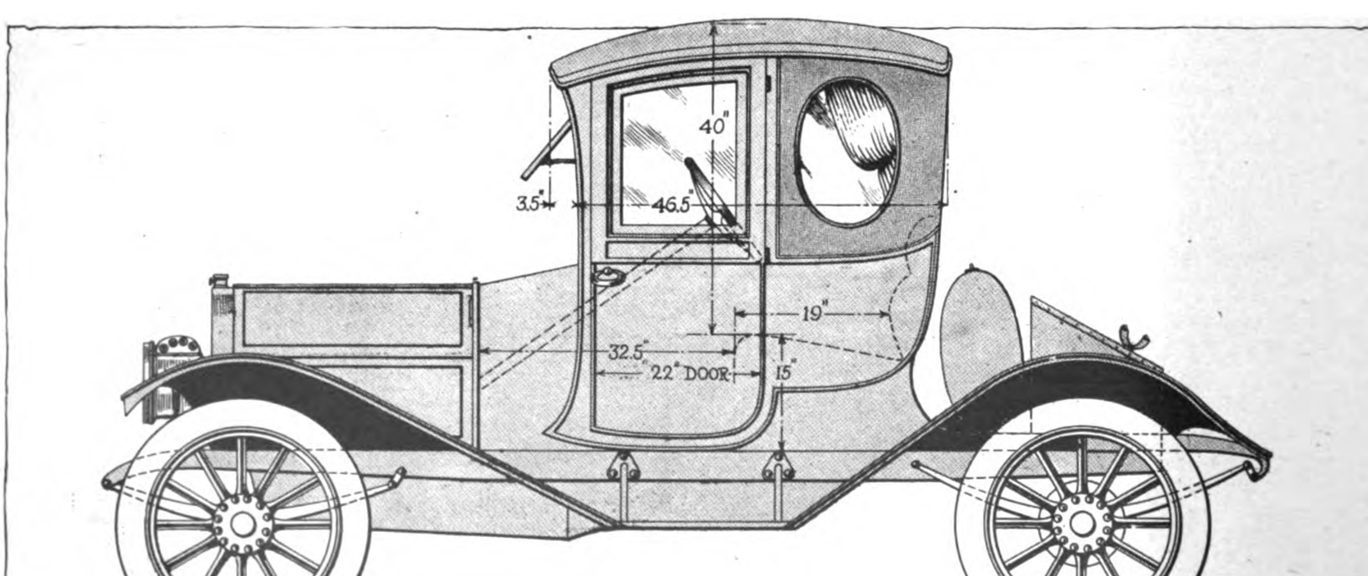

Fig. 5—Side view to scale of suggested coupé design for 1912 Overland model 59-R

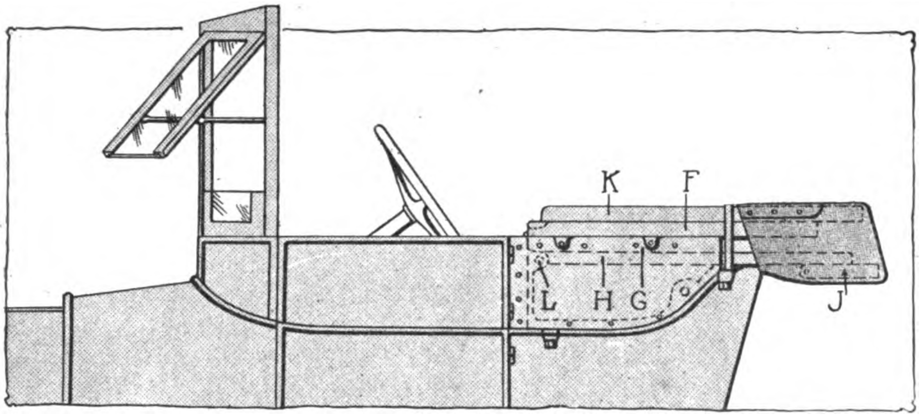

Fig. 6—View of roustabout design for Overland showing top down

For the quarter glass frames, the same provisions are made with flanges on the posts at the back and front of the frame. These frames are made to lift out when the top is lowered and can be stowed under the seat. When assembling in position with the top raised, these frames are put in from the outside, the top of the frame fitting into a pocket on each pillar. Two machine screws made specially for the purpose are then passed through lugs at the bottom, attached to the glass frame and made fast in plates inserted in the framing G, thereby securely locking the frame in position. To keep the frames from rattling and shaking loose and to insure against leakage of rain at points around the joints, all the edges of the door and quarter frames are bound with rubber channel.

returned to its original condition as an open car, as shown in Fig. 4.

Taking up the construction from the front, the windshield is made with solid panel and framing below line C, Fig. 7. The post A is connected by framing at the top to B at each side of the body and the glass is cut at D to form the visor.

The frames of the glass are of mahogany and the panel below C is formed of aluminum panel and molding.

Practically the only necessary alteration is that of a new door, which, as shown in Fig. 7, is made considerably higher than the original design.

The molding that bordered the top of the old door is shown across panel. One new door hinge is added above this molding line and the new lock is also placed above it. Conditions are allowed to remain as in the original car as much as possible to facilitate replacing the old parts, thereby permitting of the change being made without any great expense.

The door window frames are made to swing on hinges on line C and to turn down and lie flat against the inside of the door. Dotted lines E, Fig. 7, indicate the glass frame when in this position. These glass frames are of mahogany and the lower part of the frame is made extra thick to give a stable bearing when the frame is in the upright position. Spring catches, one at each side, are the means used to hold the frame erect. The posts B and F have metal flanges .0625-inch thick projecting 5 inches into the doorway, against which the door glass frame abuts when the door is closed. These flanges also form a wind break around the glass.

The large quarter glass used in connection with a collapsible top of the type illustrated is one of the distinctive features of this design and requires special construction to provide for same. The framing around the window is formed by the post or bow F at the front, the post or bow H at the rear and the horizontal framing G at the bottom. At the top between the bows F and H no framing is required, but a joint I is used to keep the bows properly separated. The joint I is also connected with the short bow J by a separate arm which is used to throw the bow into proper position when the top is folded down.

The other member to complete the folding top is the bow K. This horizontal bow engages in the bow F, as illustrated in Fig. 7, and when folded down it also engages with the same bow, and at the point where the latter breaks, as illustrated in Fig. 6.

A good quality of heavy-weight mohair or burbank of a dark color will be the most suitable material for the top cover and curtains. The top cover is fastened to the bows in such a manner as will allow folding properly. The curtains are made in five pieces; the back curtain and the quarter stays detach at the bottom and roll up, and the small curtain below the framing piece G is loosened when the top is folded and then replaced when the top is down.

A great deal of comfortable service can be obtained from a car thus equipped and the cost of changing the car from Fig. 4 to Fig. 7 will approximate an outlay of $300.

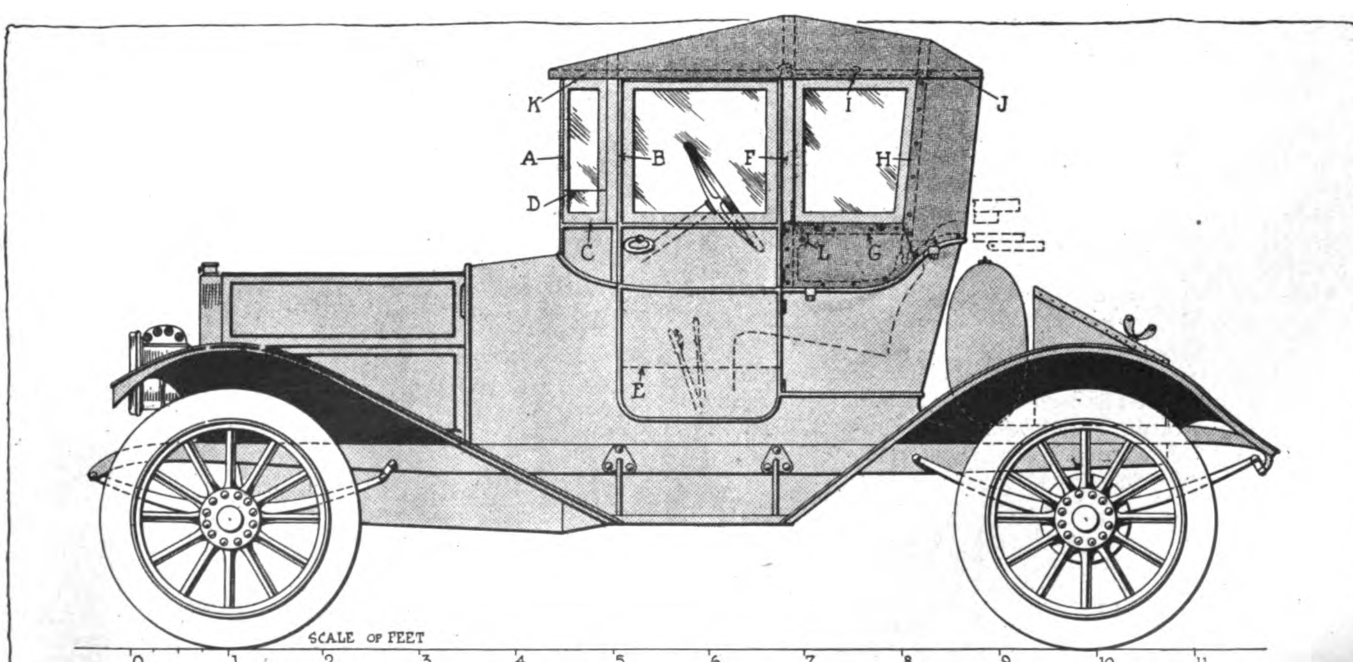

Fig. 7—Suggested collapsible hood design for Overland 1912 model 59-R

Among the New Books

Works Which Have Recently Appeared That Should Appeal to Automobilists as Well as to Those in the Industry

LABORATORY MANUAL FOR TESTING MATERIALS OF CONSTRUCTION, by L. A. Waterbury, C. E., Professor of Civil Engineering, University of Arizona, Member of the American Society for Testing Materials. Published by John Wiley & Sons, New York City. 270 pages, 5 by 7 inches, with sixty-eight illustrations. Cloth, $1.50.

While primarily intended as a manual for a school laboratory, this work is also of interest to the practical engineer wishing to brush up on certain details of material testing. The work is divided into nine chapters. The first chapter contains such information regarding the use of the different testing machines and methods of marking and conducting the tests as well as detailed instructions as to how to prepare a report. The various tools, instruments and measuring devices are taken up in the next chapter, while each of the remaining chapters deals with a specific material, including cement, concrete, iron and steel, wood, brick, sand, gravel, stone, asphalt, etc. In the appendix are several papers on subjects relating to the testing of materials.

MOTOR BODIES AND CHASSIS. By H. J. Butler, Technical Editor of *The Automobile and Carriage Builders' Journal;* Foreword by the Rt. Hon. The Lord Montagu, of Beaulieu, Editor of *The Car Illustrated*. Published by the D. Van Nostrand Company, New York City. 328 5 1-4 by 8 1-2-inch pages with numerous explanatory illustrations. Cloth, $2.50.

Up-to-date we have few complete books of this length which put into intelligible form the details of construction of the whole car from upholstery to spark-plugs. This book tells how the automobile is built. It gives specific information on every point and does not deal with the mere surface of the subject but goes to the heart of the matter. As a work which not only describes the different parts of a car but tells how each is built and gives the measurements required, it is unique. At every point it bears the mark of completeness and attention to detail.

THE MODERN GASOLINE AUTOMOBILE, ITS DESIGN, CONSTRUCTION, OPERATION AND REPAIR, by Victor W. Page, M. E., Consulting Engineer, formerly technical editor *Automobile Journal*. Published by the Norman W. Henley Publishing Company, New York City. 700 pages, 6 by 9 inches, with 500 original illustrations and ten folding plates. Cloth, $2.50.

There have been two distinct periods in American literature on the automobile. This mode of conveyance, which has probably created more interest than any other topic during the past 10 years, was the subject of many detailed writings when it first began to make itself known as a prominent factor in the world's progress. After that time there came a pause and we are now in the second period. All of this will explain why this work is modern and free from the elementary ties that bound the early authors. The book is a complete study of the automobile from fuel to upholstery. The trend in modern practice is outlined in the early chapters and step by step every portion of the motor, chassis and body are taken up and discussed. The illustrations are new and original. The Knight sliding sleeve valve and several of the later developments in rotary valves are explained. Of special value is the chapter on upkeep of the car.

MODERN MACHINE SHOP CONSTRUCTION, EQUIPMENT AND MANAGEMENT, by Oscar E. Perrigo, M. E., Member of the American Society of Mechanical Engineers. Published by the Norman W. Henley Publishing Company, New York City. 343 pages, 7 by 10 inches, with more than 200 illustrations. Cloth, $5.

In view of the interest which is just at present felt in factory efficiency a work of this kind should attract universal attention. The laying out of a plant has so much to do with the quality of the work that is turned out as well as with the cost of turning it out that too much cannot be said on the subject. In the first part of the book the author goes into details regarding the construction of the plant. He points out the various methods in use for different parts of the factory and gives elaborate directions regarding the use of specific materials for salient points in the construction work. The illustrations in this part of the work show how the actual building of some of the most modern factories is carried out, telling how certain puzzling problems have been met and solved. In the second part of the work the equipment and its arrangement have been touched upon, as has also the proper space to be allotted to each department and where they should be placed. The third part of the work takes up the actual system of management and paying of the men, the well-being of the employees and the authority to be vested in each of the foremen. The question of the superintendent's office and its work is given special attention.

GAS AND OIL ENGINES, by Alfred Kirschke, translated from the German and adapted to English practice by Charles Salter. Published by Scott, Greenwood and Son. Sold in the United States through D. Van Nostrand Company, New York. 158 pages, 4 1-4 by 7 1-2 inches, with 55 illustrations. Cloth $1.25.

This is a description of the principles of the more important developments in the gas engine field since 1860. It is a work more for the man interested in the larger gas engines than for one who is chiefly concerned with the smaller types. An especially good chapter on the Diesel motor and the principles of its operation lends considerable value to the work. The author, who is chiefly known through his efforts as lecturer at the State and Municipal School of Handicrafts, Halle, England, has touched upon the salient features of the best recognized types of motor and has contrasted these and compared them with a view of presenting a broad view of the entire situation.

PRIMER OF SCIENTIFIC MANAGEMENT. By Frank B. Gilbreth, member American Society of Mechanical Engineers. Introduction by Louis D. Brandeis. Published by D. Van Nostrand Company, New York City. 103 5 by 8-inch pages. Cloth. $1.00.

What is Scientific Management as an art? What is the Taylor system? How can I introduce the principles of cost saving into my business without destroying it? All these questions and many others are answered in this book which does not pretend to be a complete discourse on Scientific Management, but merely as the title states—a primer.

TOUR BOOK OF THE CALIFORNIA STATE AUTOMOBILE ASSOCIATION.. Published by the association. 630 pages, with maps Cloth, $2.50. Paper, $1.50.

Several hundred tours throughout the States on the West coast are mapped and outlined and the work contains all the valuable information that a book having routed tours generally has for the automobilist. Some unique and good features are incorporated in the way the book is laid out among them may be mentioned the large type used in numbering the pages and the complete index.

THE DRAFTING OF CAMS, by Louis Rouillion. Published by the Norman W. Henley Publishing Company, New York City. Twenty-four pages, pamphlet form, with sixteen explanatory figures. Price, 25 cents.

One of a series of practical papers issued by the same concern. This deals with the laying out of cams for al purposes and gives drafting-room directions on the method of drawing each.

PRIMARY BATTERY IGNITION, by C. Wadsworth, Jr. Published by the D. Van Nostrand Company. Seventy-seven pages, with twenty-eight illustrations. Boards, $1.50.

A little work on battery ignition that serves a worthy purpose in that it explains some of the simpler instruments and at the same time gives an insight into the workings of a battery ignition system. The high-tension coil is taken up in detail and practical information is given as to its adjustment. It is printed clearly on good paper and is written in such a way that no one should have difficulty in following the author.

Recording Work of Automobile Salesmen

New York Selling Organizations Use a Number of Blanks for Keeping Track of Salesmen's Arrangements

Elimination of Chance Work, the One-Man Idea and of Inefficiency Are the Aims of This System

SALESMEN, like other mortals, must do their work in a systematic way to accomplish things. The advantage of system, as in other fields of endeavor, is increased capability of the salesman to help himself and the firm, and the abolition, at least to a certain extent, of the one-man principle which is considered a detriment to modern business. Control of their activities may not look an attractive thing to the vanity of some salesmen, but the good ones among them generally recognize their own advantage in a progressive policy. Since a general staff officer in the army submits to a discipline and system, there is no reason why a salesman should not.

The A. Elliott Ranney Company, New York City, representatives of the Hudson Company, takes the sensible view that whatever means go to increase the efficiency of the salesroom and men are desirable, has developed a system on the ground of this principle. The fundamental scheme is the inducement of the salesmen to do as much work as is in their power and to give each man the credit which is due to him. This system has been the reason, to a considerable degree, that the company just mentioned has developed a splendid business during the past few years.

The system by means of which the salesmen's work is recorded includes a number of forms. On these forms daily, and in some cases weekly, records are entered, by which the salesmen inform the company of the calls made by them and the sales which they have closed; whereas in the communications from the firm to the sales staff the latter is informed of the standing of each man. Following are the forms used in the Hudson salesmen system of the Metropolitan branch:

1. Daily report of each individual salesman, giving the total of the work done by the writer and the various items constituting it.
2. Master card, giving the name of every prospect owner, which is made out and filed on the day when the first call is made.
3. Sales record made out by the salesman as soon as a transaction is closed.
4. Weekly sales statement given out by the firm to the salesmen.
5. A more detailed weekly statement which is kept in the office, giving the amounts paid to the company during the week, and during the selling season, being, thus, a sales statement.

Another form which is not in use by the Hudson branch in New York, but which should prove very useful if introduced, would be—

6. Layout of salesman's work for the next day, giving the appointments made, the arrangements made with the demonstrator, etc.; in short, all that is arranged beforehand and cannot be ignored without the possibility of complications arising therefrom.

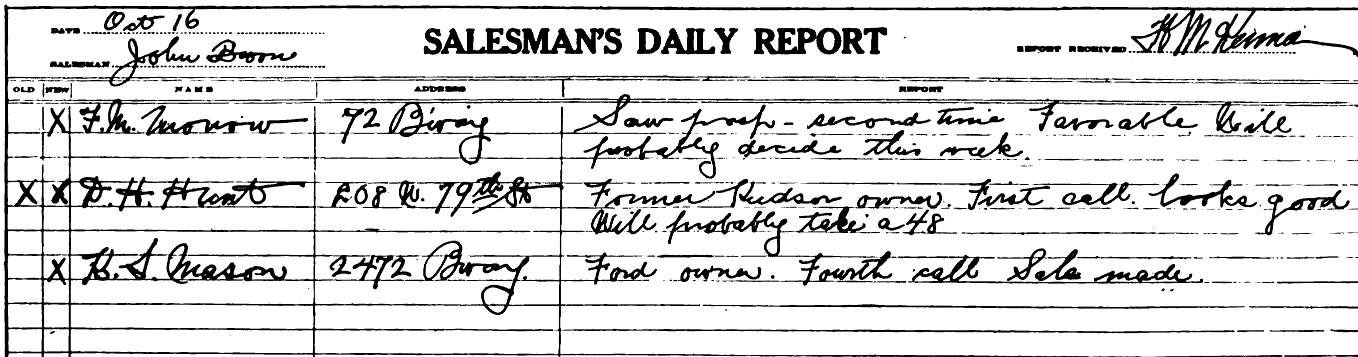
Fig. 1 shows the daily salesman's report, which is made out on a white blank, 14 inches wide and 7 inches deep, lined and printed in black. The blanks are kept in pads, and every salesman upon returning to the store at the close of the day fills out one blank, in the manner indicated in Fig. 1. He enters his name and the date on the form, and then reports every call he made. This is done with considerable detail, as shown by the three cases appearing in Fig. 1. Besides name and address of every party called upon, the circumstances worthy of being recorded are noted. Furthermore, in the case of each prospect owner it is stated whether he has owned Hudson cars before or not.

Upon the basis of the information afforded by the daily salesmen's reports the master cards are filled out, one being shown in Fig. 2. This form is 8 inches wide and 5 inches deep, and lined red and blue, with black printing. Spaces are provided for name and address of the prospect owner, under whose name the card is filed. All master cards are numbered in rotation as they are filled out. The name of the salesman and the dates of his first visit and of his demonstration also find their place at the head of the form. All the space below the heavy black line is given to details which appear on the daily report cards of John Brown, and the card is large enough to permit of entering details of a dozen calls, using both sides of the form.

The sales record, Fig. 3, is made out by a salesman when he closes a transaction. This form mentions whether the purchaser is a former Hudson owner or not, as the company keeps exact records of the nature of its business. Of course, a salesman keeps a record of the sale in his own notebook, but this is outside of the scope of the company's system.

One of the purposes of this system is to breed confidence in the firm, and when a salesman has been assigned a prospect and has properly followed him up he is entitled to the percentage on the sale, even if the transaction should be closed on the floor while he is not in the store. By this condition salesmen are induced to spend only a minimum of their time on the floor; that is, when they take their turn in salesroom service. They in turn spend a day in the salesroom to take care of the parties who come in from the street.

At the end of every week a statement, Fig. 4, is made out by the firm and a copy is given to every salesman or agent mentioned on the form. This gives the salesmen a chance of comparing their achievements, and calls their attention to an error, if such should occur in the crediting of sales to the men. The weekly sales report covering the work of the salesmen for the week and season until the end of the week is typewritten for the office records of the firm, being made out as follows:



SALESMAN'S DAILY REPORT

Date Oct 16

Salesman John Brown

Report received K M Hemma

Old	New	Name	Address	Report
	X	F. M. Morrow	72 B'way	Saw prosp - second time Favorable Will probably decide this week.
X	X	D. H. Hunt	208 W. 79th St	Former Hudson owner. First call. Looks good Will probably take a 48
	X	R. S. Mason	2472 B'way.	Ford owner. Fourth call Sale made.

SALES LETTER RECORD

Oct. 3—Address by Mr. George M. Bell, 145 East 55th street. First call on prospect. Seems doubtful. Owns Ford, is in favor of buying another one this year. Will, however, have 37 demonstrated to him next week.

Oct. 8—Saw prospect at 2:30 p.m. Showed car, gave demonstration; 10 miles on Long Island. Liked car, but will wait for some other demonstrations and decide in a week.

Oct. 13—Called again, third time. Promised to decide on the 16th.

Oct. 16—Fourth call. Sale made. Full equipment. To be delivered, if possible, on Nov. 7.

Fig. 2—Master card of Hudson sales company, which is made out for every prospect owner

WEEKLY SALES REPORT OF A. ELLIOTT RANNEY COMPANY, NEW YORK, ITS BRANCHES AND AGENTS, FOR THE WEEK ENDING SATURDAY, OCTOBER 26, 1912.

New owners	37 per cent.
Other makes	17 per cent.
Total	100 per cent.

Comparative Weekly Statement of Sales Made During the 1912 and 1913 Seasons

	1912 Season	1913 Season
Number of cars sold by salesmen during 15 weeks	29	35
Number of cars sold by agents during 15 weeks	17	11
	46	46

This statement shows not only the number of cars sold by the various selling individuals and companies, but also the influx of cash during the week and the selling season so far progressed. It also shows the proportion of old Hudson owners among the buyers of new cars, thereby giving the company, and through it the factory, a chance of feeling the public pulse. This is one of the great points of this system. The weekly office record affords also a comparison of the business done during the present season with that of the previous one.

A system which is similar to that of the Ranney company in many ways and which has also been worked out with great care, is that of the New York branch of the American Locomotive Company. The forms used by this company are shown in the cut appearing on page 1057. Besides a sales blank is used.

The daily report and the master card are very similar to those used by the Hudson representatives, except for the provision of additional detail on the master card. The latter is 8 by 5 inches, and the daily report 11 by 8.25 inches, with blue lines and black letter printing. The daily out report is a sheet somewhat larger than the salesman's daily report and which is always kept on a desk in the salesroom. On this sheet each salesman, as he goes out, enters the time of his leaving and when he expects to return, as well as the parties whom he goes to see, in their proper order.

In this connection the system by means of which track is kept of the salesmen's appointments, as they come into effect, is worthy of mention. The salesmen when making appointments enter them on their daily report sheets, and when the stenographer at the office goes over these sheets and transfers their contents to the master cards, she also fills out appointment cards, Fig. 9, which are filed in order of the critical dates. As the dates of these engagements come up, the girl makes out a yellow slip for each appointment, and hands it to the salesman on the morning of the right day. In this way, part of the salesman's work for a day is outlined for him when getting to the salesroom in the morning. As to new prospects, these are assigned to him by the sales manager, who first receives all inquiries which come in. The manager distributes the work fairly equally among the salesmen, except where cases call for special skill with particular classes of prospects. Certain salesmen are used to follow up interested brokers, and others interested private prospects, and so forth. Likewise, different men cope with the pleasure car and truck situation, respectively. To assign a new prospect to a salesman, the manager fills out the card, Fig. 8, held by a perforation to Fig. 10. The former is filed in the office and the latter given to the salesman.

In the Alco Company's store a salesman must follow up a prospect to such an extent that a resulting order gives him a moral right to the commission on the deal. If a salesman calls upon a prospect only once or twice and the latter drops in after a month to buy a car, this is hardly considered the result of the man's work. If, on the other hand, a salesman calls on a prospect half a dozen times, and a car is finally sold to him in the store, while the salesman is not there, he is credited, in the case of either organization, with the sale. The Alco Company has a rule that when two men work on one prospect, credit goes to the salesman who did five-eighths of the work of getting him. To give an idea of this work, the average time necessary to bring about a sale in the Alco line is from ten to twelve calls for a pleasure car of the $6,000 type, and about twenty times for a truck.

Sales for Week ending.....October 26th, 1912

Salesman	Model 56	37	Total
Brown	1	1	16
Allen	0	1	9
Smith	1	1	5
Jones	2	1	5
Buckeye Auto. Co	1	1	7
Common Sense Auto Co	0	1	4
	5	6	46 to date

Fig. 4—Weekly sales statement given to Hudson salesmen

One form which is suggested above under (6), is not used by either the Hudson or Alco companies. This is a layout, made by the salesman, which covers the work he expects to do during the day. This form would take the combined place of the appointment and daily out blanks, and be kept on the salesman's desk. It would be even more exact and true to the situation than the layout formed by the duplicates of the appointment slips, Fig. 9. Another point on which improvement is possible, is the matter of regular communication between salesman and office. The salesman who makes it a point to call up headquarters at regular hours, say at 10.30 and 3 o'clock, will save himself time in many cases, and will be sure that no important matter relating to his trade is delayed in the office or salesroom.

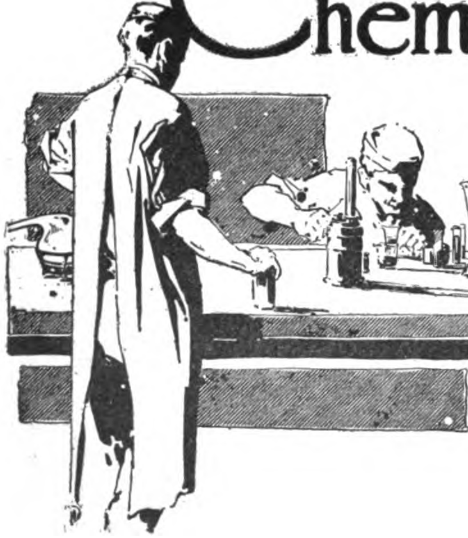
The Chemistry of Cylinder Oils



Considerable Variation in Gravity and Viscosity Found to Exist in Same Grade of Different Brands

Part IV

Being the fourth of a series of articles on cylinder oils which will appear from week to week. Discussions are invited and the columns of THE AUTOMOBILE *are open to pertinent criticisms.*

By W. Jones

IN Table B we give the analyses of forty samples of oil, all of which were obtained in New York City. The different brands are represented by letters, and the different grades of each brand are shown by numbers. These letters and numbers will be carried through all analyses to represent the brand and grade.

This table of analyses is given to show what the various brands of oils are, at the present time in the city of New York, and for comparison with the same brands to be obtained in other cities. While this is the primary object of these analyses, the table may also be of much use in comparing the different brands, one with the other, being, of course, careful to always compare the same grades, in the different brands. These different grades are, as above stated, marked by figures and are so arranged that the same figure in each brand shows the same grade, and where there is only one grade it has been marked so as to correspond to a similar grade in the other brands.

We have in brand A eight different grades. No. 1-a and No. 2-a, are water-white oils. No. 1-a is marked light and No. 2-a is marked medium. The two oils are, however, almost of the same gravity, and there is not much difference in the viscosity, and notwithstanding they are so near alike, No. 2-a, which is marked medium, is, in fact, a lighter oil than No. 1-a. These two oils may be compared with brand M, which is also a water-white oil. These three are the only white oils in the list, and we have added the letter to the number to indicate them.

There are some very interesting points to be observed about these three oils:

First, the gravity is almost the same in all three, although they are quite different oils and come from different sources. They are the only oils we so far have **with a gravity as low** as .8686, and there is only one other oil **which has a carbon** figure as low as these.

Second, while the gravity is almost t**he same, the viscosity** at 80 degrees Fahrenheit is very differ**ent. In brand M we** have the viscosity 1.7647, and in brand **A, No. 1-a and No.** 2-a, we have 4.2857 and 4.128, this alon**e showing the oils to** be quite different, but at the temperat**ure of 350, all three** oils are very much alike.

The flash and fire points are of cours**e quite a little higher** for the thicker oils.

We may also go a step further and s**how the total sulphur** in brand A. No. 1-a is the lowest we **have so far found in** any of these oils, being only 0.046 per **cent., while that in** brand M is 0.049.

We have also determined the heat of **combustion of these two oils, and find them very nearly the same, for brand A No. 1-a, we have 19,798 B.t.u. and for brand M we have 19,708 B.t.u. This is the highest heat of combustion we have yet found, and the only other one we have at these figures is brand H No. 1, where we have 19,761 B.t.u., and it is also curious to note that the sulphur in this oil is also low, being only 0.049 per cent. and the carbon is the only low carbon we have, being 0.34 per cent. As brand H is not a white oil, it is quite obvious that we need not select a white oil as giving the best results.**

The other oils in this list are of all shades of color, from light to dark, and as a rule the thicker they are the darker they are. All the grades marked No. 1 come labeled light; those marked No. 2, as medium; those marked No. 3 as heavy. These three grades seem to be the most in use and these numbers in the different brands should be compared together. Of the other numbers, Nos. 4 and 5 are special oils, and No. 6 is extra heavy. I will call attention here to brand I No. 3, which is a very thick oil; however the oils in this brand are marked light, medium and heavy.

In comparing the Nos. 1, 2 and 3 of each brand we find the gravity to vary considerably:

In	No. 1	from	.8705	in brand	F	to	.9153	in brand	J
"	" 2	"	.8756	" "	E	"	.9108	" "	J
"	" 3	"	.8801	" "	E	"	.8955	" "	H

In the viscosities at 80 degrees Fahrenheit we find a variation as follows:

In	No. 1	from	2.2500	in brand	C	to	7.500	in brand	J
"	" 2	"	3.5714	" "	F	"	9.2857	" "	I
"	" 3	"	4.6071	" "	C	"	54.6428	" "	I

This would show at once the uselessness of purchasing oil by the brand and grade or by name only, without knowing just what the oil represented really is.

Going back again to the viscosities, we find that in the three grades in all the brands we have a variation in the viscosity at 80 degrees Fahrenheit from 3.2353, in brand A to 54.6428; in brand I a variation of 51.4075, yet at a temperature of 212 degrees Fahrenheit we have a variation of only 2.7500; while still further at 350 degrees Fahrenheit we find only a difference of 0.1428, and this is including brand I No. 3, which has a viscosity at 80 degrees Fahrenheit of 54.6428.

We think there could be very little advantage in using the thick oil, while there certainly would be a great disadvantage in the amount of carbon it would give. Selecting an oil from this table, from the carbon figures, we would pick out brand H No. 1, which has a carbon figure of 0.34, and about the last we would take would be brand I No. 3, with a carbon figure of 2.33 per cent., or nearly 2 per cent. more. This would certainly overcome any slight increase in the lubricating properties of the thick oil, due to its higher viscosity.

In brand B we have two oils of the same grade, but we notice they are quite different oils. In brand C we find Nos. 1, 2 and 3 in duplicate, and here again we see a large difference not only in the viscosity, but also in the carbon.

It is very possible that this is as close as oils can be prepared on a commercial basis, but this is a point we would like to find out. If they are liable to differ as much as these do in this brand C, it would seem advisable for large users to purchase their oils on specification.

(To be continued.)

Weak Spots in Our Lubricating Systems

THE greatest difficulty found in lubricating a motor is to supply the oil in proportion to the speed at which the bearing surfaces are moving over each other. When two metal plane surfaces are in moving contact the movement is resisted by a variable amount of friction. Sliding contact produces a higher friction than does rolling contact because the area over which the force of friction is exerted is great in the first instance while in the rolling contact the area is practically nil, being merely a point or a line. **As the speed increases, the resistance per unit of time, or, in other words, the power of the resistance is augmented.**

The power that is used in overcoming frictional resistance is transformed to a large degree into heat. **Hence, when the coefficient of friction rises, the heat increases and along with the rise in heat come a consequent rise in the coefficient of friction.** This continues until the resistance becomes so high that the power exerted by the friction is greater than the power utilized in driving the moving parts and the bearing binds and the result is what is known as a seized or frozen bearing.

In a bearing there are two factors which could increase the coefficient of friction where a given amount of oil is supplied. The first is a rise in the temperature of the metal and the second is a poor condition of the bearing itself.

With the above conditions in mind a study of how the oil reaches the cylinder wall is of particular interest. **In the average form of splash system there is a marked tendency towards feeding too much oil at low speeds in order that there will be enough at high speeds. It is a matter of doubt that the amount of oil splashed up by the scoops on the connecting rods increases with the speed.** When the connecting rod is whirled around at high speed it would seem that it would sweep every vestige of oil out of the narrow trough which is generally made to hold it. With such high speed, when the motor is turning over say 1800 revolutions a minute, with the connecting rod passing through the trough every 1-30 part of a second, is it possible to renew the oil in the trough as thoroughly as when the connecting rod is moving at half that speed? Hence, it may well be asked if in the splash system the oil is fed to the cylinders in an increasing ratio with the increase in speed. **If we design the lubricating system for average touring speed we are getting insufficient oil at high speeds and our motor smokes at low speeds.** Can this be overcome by any modification of design such as troughs interconnected with the throttle, being raised and lowered by its motion; or by replenishing the oil supply to the troughs by pumps having a greatly increased delivery at high motor speeds? A small fraction of a second is a short time, and the tendency towards other systems is perhaps the explanation.

(To be continued.)

The Engineers' Forum

3-Point vs. 4-Point

Discussion of Relative Merits of These Systems for Motor and Gearbox Support Continued from Last Week

Dunham Favors Four-Point System and Cites Many Advantages—Souther Leans to Three-Point

Part II

Henry Souther Expresses His Views

George W. Dunham Emphatic for Four-Point

J. G. Perrin States Four-Point Merits

Chester S. Ricker Talks for Three-Point

Stewart McDonald Believes in Four-Point System

HARTFORD, CONN.—Editor THE AUTOMOBILE:—Regarding three-point as compared with four-point suspension for motors and gearsets, my inclination as an engineer has always been for the former, and I have assisted in the design of cars using it and have used cars myself so constructed. I know that it is a good thing only if properly applied.

The principle, I have felt, is right, because it is impossible to make a rigid frame and not very practical to make a motorbase or a gearbox strong enough to prevent the frame or its supports from yielding and bending.

I have seen many four-point suspension engine legs and gearbox legs broken by the flexing of the frame and because the application of the four-point support was not good.

Four-point suspension can be applied so as to permit enough motion to relieve all strains from engine base of gearbox; in fact, that is done by several cars of well-known construction. At the same time, I believe the three-point suspension is the easier to construct and therefore, all other things being equal, the better.—HENRY SOUTHER, Consulting Engineer.

Finds Four-Point System Best

DETROIT, MICH.—Editor THE AUTOMOBILE:—Just a few words in plain English, eliminating technical expressions: On the face of it, it would appear that three-point suspension is the only construction worthy of consideration. Theoretically, anything but three-point suspension is unmechanical, but actual experience demonstrates that four-joint suspension is undoubtedly the most all-around satisfactory.

Examination of the automobile as it is built today shows that four-point suspension is the best accepted practice. This suspension, four-joint, is undoubtedly possible, only on account of the extreme flexibility of an automobile chassis, and while it would seem that a motor bolted down to the frame at four points is bound to be sprung out of shape, on account of the giving of the frame, in actual service just the reverse is true—the frame supplying the flexibility and the motor holding practically rigid.

There are so many advantages connected with the four-point method that it would seem the three-point suspension must have originated from one of three causes: First, theorizing; second, lack of rigidity in motor design and construction, and, third, desire of the engineers to construct the car theoretically correct in every detail, rather than obtaining the results by the most direct means.

There are a number of cars with so-called three-point suspension, but, in fact, there are very few embodying this construction. I have in mind a motor supported at one end by means of feet extending out onto the frame rails, and at the other end there is a rigid cross-member, to which the motor is securely bolted by two bolts in close proximity. This would seem to be three-point suspension, but if one stops to consider the securing of the end with two bolts close together makes a rigid suspension and is practically the same as four-point insofar as all practical results are concerned.

In argument for and against the two methods, I merely wish to call attention to the fact that in machine construction, often those which appear unmechanical are the best, and where there is but little difference one way or the other, the simplest and the shortest cut to the result is undoubtedly the most advisable method.

I believe that in the contest work during the entire history of the automobile, in practically every case where a large number of events were entered and a large percentage of these events won, the suspension was four-point.

To sum up the situation in a practical way, and that is the way in which the average automobile buyer looks at it, the following are a few points, the consideration of which should give one a fair idea of motor suspension:

First—A big majority of successful racing contest cars have four-point suspension.

Second—A big majority of the best cars built today have four-point suspension.

Third—The motor with four points of suspension is more stable and less inclined to rock under heavy loads under varying conditions.

Fourth—The three-point suspension is undoubtedly theoretically correct, just as much as the sliding gearset, which is universally used, is absolutely unmechanical and opposed to all theory.

Would not careful consideration of the above lead one to choose the four-point construction?—GEORGE W. DUNHAM, Chalmers Motor Company.

Disapproves of Flexible Mounting

DETROIT, MICH.—Editor THE AUTOMOBILE:—My experience with three-point suspensions has not been very favorable either with engines or unit power plants, where the point of the triangle is on the front cross member.

With the fore-door type bodies and enclosed jobs, I have obtained much greater satisfaction with a good, rigid frame, the motor and gear-box being fastened thereto very rigidly, than where schemes for flexible mounting have been used.

Of course, with a rigid frame having power unit and body fastened to same more or less rigidly throughout, a very easy spring suspension is advisable, and, in fact, almost a necessity.

On light cars, of course, things can be done in the way of flexible suspensions which would not work out so well on larger and heavier cars. We found in racing, and especially in 24-hour races, that we got much better results where the engine was fastened to the frame at four points than where we tried to arrange for a flexible mounting of engine.

I do not imagine a more severe test can be made to show up faulty construction of power plant and frame and axle than during the latter half of a 24-hour race when track at corners especially is only a little better than a plowed field.

I might qualify the above description of our engine mounting as regards the power plant being rigidly fastened to frame by stating that the two front engine arms are hung on brackets of sheet metal which are more or less flexible and the engine arms are not therefore directly attached to side members of frame.—J. G. Perrin, Lozier Motor Company.

—

Illustrates Three-Point's Advantages

Indianapolis, Ind.—Editor The Automobile:—It has been utterly impossible for me to give you any story on three-point suspension, but I instructed a photographer to get some photographs which I feel will explain more than anything I could say regarding the advantages of three-point suspension.

You will note from the front view of the car, Fig. 1, how much the car has been distorted in order to show the effect of exceedingly rough going on the motor car chassis. The diagonally opposite wheels in this case have been raised 10 inches in order to obtain the effect shown. As a measure of the distortion, you can notice the position of the center of the starting-crank shaft. This normally is at the center of the slot in the front cross-member. In the photographs this actually touches the side of the slot. That means that the motor has been twisted over to one side very nearly 1 inch, yet I readily cranked the motor, proving that none of the bearings was in the least pinched by this distortion. This is a proof that the three-point suspension is certainly worth while.

The second photograph, Fig. 2, shows the method of supporting the motor and the trunnion at the front of the motor is shown through the fan. In this photograph you can gain some idea of the construction, some of the points of which I will enumerate below.

The rear supporting member for the motor is only held in place by two bolts, one of which is shown at the rear end of the crankcase. The weight of the motor is carried, however, on the long rectangular projection milled on the rear end of the crankcase. This projection is horizontal and extends the full width of the aluminum case.

The steel cross-member which fastens on this is slotted so as to receive the projection on the crankcase. As a result the motor support has a bearing 1.5 inch wide and about 14 inches long, thus relieving the bolts from any shearing strains.—Chester S. Ricker, Henderson Motor Car Company.

—

Four-Point on Four-Cylinder Cars

St. Louis, Mo.—Editor The Automobile:—There are a number of conditions present in the four-cylinder motor which call for greater rigidity than with the six-cylinder, and hence a stronger, more rigid form of support is considered essential by us.

With the four-cylinder motor there is more vibration due to the unbalanced relation of the connecting-rods at the upper and lower dead points, because of their angularity.

This vibration is best cared for, we think, by providing four-point support for the engine when it is a four-cylinder.

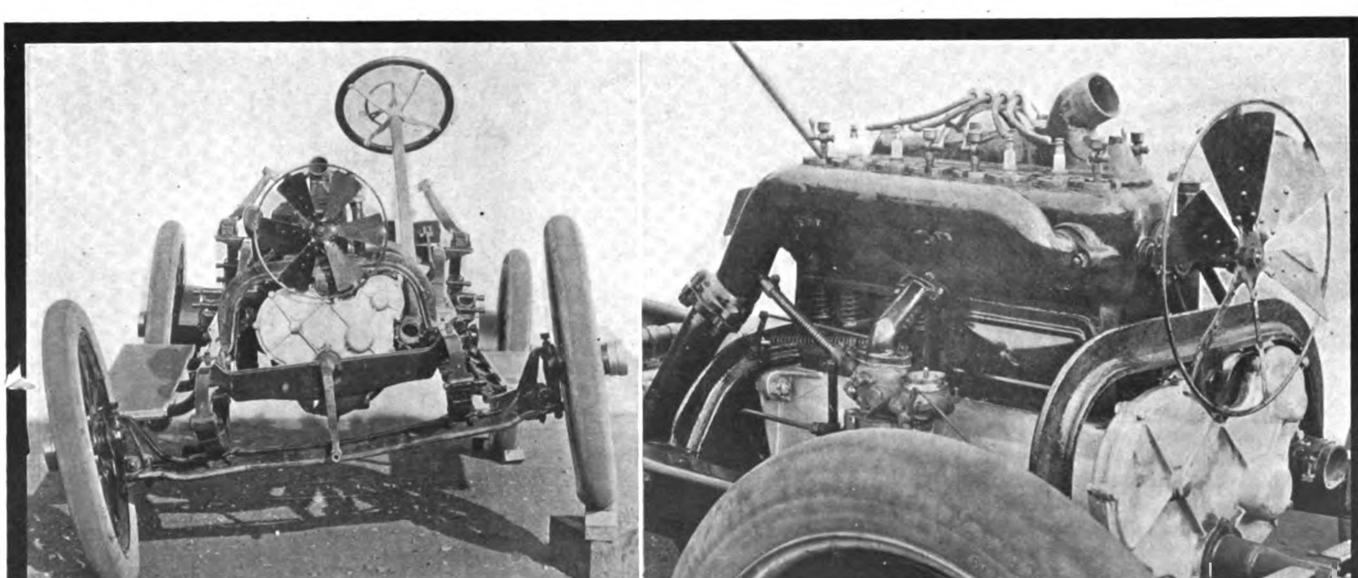
Then, too, the distortion of the frame due to uneven roads does not seriously affect a four-cylinder motor because the cranks are 180 degrees apart.

With the six-cylinder motor the vibration is more effectively eliminated both with respect to unbalanced forces and unbalanced couples, and hence three-point suspension affords ample support and vibrational resistance.

Furthermore, the cranks of the six-cylinder engine being only 120 degrees apart, the frame distortions due to road unevenness are more serious in their effects.

For these reasons we utilized four-point suspension on our four-cylinder motors and three-point suspension on our six-cylinder motors.

Another element to be considered, of course, is the increase in the frame distortion effect upon a motor which measures longer—the effect upon a four-cylinder being much less than upon a six-cylinder of the same stroke and bore.—Stewart McDonald, Moon Motor Car Company.



Importance of Proper Weight Distribution; Priming Device for Acetylene; Cannot Start His Motor; Ether as a Priming Agent; Shellacked Hose Hard to Remove; Removing Carbon from Opposed Cylinders; Toe-In Explained

Weight Distribution Important

EDITOR THE AUTOMOBILE:—Mr. MacNutt does some designs of cars an injustice when he says that it is necessary to use chains to get traction. It is all a matter of proper weight distribution. If the larger portion of the weight is on the rear and the engine nearly able to wind the front end up into the air as it tries to turn the rear axle then a condition is produced where practically all the weight is on the drivers and they will take that rig anywhere. I do not know when the buying public will learn this simple fact, but I live in hope that they will some day. They talk quite learnedly about four-wheel drives, but what is the use of a four-wheel drive when it is possible to carry practically all the weight in the driving wheels and get nearly the same result anyhow?

I must disagree with him as to the effect of chains on the tires. I submit that a road made of chains will wear out the tires much faster than a smooth road, and I fail to see any difference if the wheel carries the chain instead of the road carrying it. That a chain fixed across the tire will quickly wear it out, no one denies. That a loose chain does not hit twice in the same place and so does not make its damage apparent so soon is also true, but that the wear caused by chains "is inappreciable" I do not believe. Weight on the driving wheels is the right answer. If Mr. N. will inject a teaspoonful of sulphuric ether and gasoline in equal parts into his cylinders he will get results on cold mornings.

Saginaw, Mich. CHARLES E. DURYEA.

—Distribution of the weight is important, but it would seem that for traction the co-efficient of friction between the vehicle and the road would be even more important.

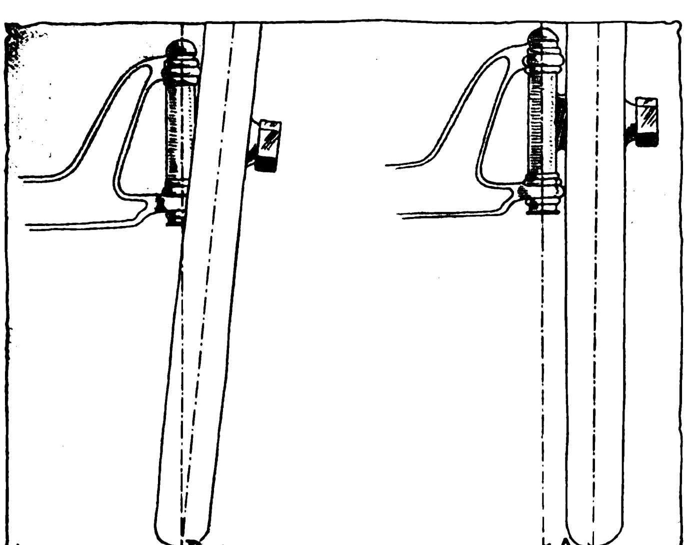


Fig. 1—Diagrammatic view of two conditions of front wheels

Reader Suggests Priming Device

Editor THE AUTOMOBILE:—Kindly advise me through Letters Answered and Discussed is there a priming valve made which accomplishes the action I describe and partly illustrate in accompanying sketch. I mean a valve, such as in Fig. 2, which will allow acetylene gas to flow into the inlet manifold, thereby filling the cylinders with gas, if it is pressed just previous to switching off the current on stopping the motor. That should leave the cylinders filled with gas and ready to explode when battery current is applied to the plugs. At the same time the button on the dash should be pressed, giving engine a good start. Should the car stand long in a cold garage, as in my case, and gas escape from the cylinders one could pull up on the starting handle and the same time pull a little wire hook in front of the radiator which would release the valve and allow entrance of gas into the cylinder, thereby making starting easy. I have been using a device, Fig. 3, which was described in THE AUTOMOBILE about a year ago and which has saved me many an hour of back-breaking work in trying to start the motor on cold mornings, but I wish to improve on that.

New York City. R. H. PANKOW.

—There are many devices on the market such as you have described, most of them being used in connection with starters. With such a device it would not often be necessary to crank as the gas would enter the cylinder if the valves were opened just before the motor stopped after the spark was turned off and would remain there at atmospheric pressure for a long time. It would be merely necessary to start on the spark in probably 75 per cent. of the cases in which the motor was warm. In cold weather the addition of such a priming device would be valuable. The device you mention as having tried with success is merely another application of the same principle and has been used with success by many motorists.

Motor Will Not Start

Editor THE AUTOMOBILE:—Would you kindly tell me how to remedy the following trouble:

The engine of my car cannot be started. Priming does no good, the engine does not give a single explosion. Carbureter has been opened and closed, but it does not seem to have any effect.

The plugs are in A1 condition. I am using a Holly carbureter on a four-cylinder Wood car.

Plainfield, N. J. READER.

—There are but two conditions necessary for securing an explosion in the cylinder of a motor. The first is that you have an explosive charge within the cylinder and the second is that you have a spark to explode it. To secure continuous explosions is another matter, as this brings in all the functions of the motor. To secure the first condition, however, requires but the two necessities mentioned. Since you are unable to get any explosion at all your problem is one in which these two factors are to be considered.

An explosive charge may be introduced into the cylinder through the priming cup. The addition of four or five drops of ether to each cylinder will also tend to make this charge more explosive. If this is done on each cylinder and you find that on turning the motor over you get no explosion, you may attribute the trouble to the fact that the ignition system fails within the cylinder in spite of the fact that the spark-plugs are evidently in the best of condition. Remove the plugs from the cylinders and lay them upon the tops of the cylinders so that the metal on the outside of the plugs is in contact with the cylinders. Turn the motor over slowly by hand and see if there is a spark at the gaps on all four cylinders. Note the sparks carefully and see if they are bright, live flashes. This can be done better in the dark. If they are not good on either the battery or magneto, the points are too far apart and should be moved more closely together. Examine all the wiring connections and see if they are tightly and carefully made. Much current can be lost through a poor connection.

If you are using battery ignition, see if it measures up to the required strength of 6 volts. Then follow along the wiring to the coil. Note if the ground connection is good. This is often a source of weakness. See if the vibrator points are adjusted correctly. When the switch is on, a steady hum like the buzzing of a bee should emanate from the coil box. If not, dress platinum points flat by filing lightly and turning the adjustment screw until the hum is of the correct pitch. If coil is not right send it to the maker for repair, as the chances are decidedly against your improving it by attempting to disassemble it.

If, after putting the ignition system in good order and introducing an explosive charge into the cylinder, the motor does not fire regularly all the symptoms and notes possible should be made and forwarded to this department for a further explanation.

Believes in Use of Ether

Editor THE AUTOMOBILE:—I notice in the issue of November 7 a discussion regarding the use of ether in gasoline to offset the effect of bad gasoline. I beg to advise that my experience had been that 10 to 12 ounces of ether, added to 10 gallons of gasoline, makes the gasoline operate about as well as the highest-grade gasoline that can be bought. I have introduced this amount into mine and 10-cent gasoline. Commercial ether is very cheap, costing only about 18 to 20 cents a pound.

There is practically no water in commercial ether and its affinity for water is so great that it will saturate and practically eat up any small amount of water which there is in the gasoline. I have been able to run an automobile engine experimentally in 60 per cent. water and 40 per cent. ether.

Milwaukee, Wis. P. C. AVERY.

—In view of the general prediction of a rigid winter and also taking cognizance of the growing desire of the automobilist to use his car in the winter as well as the summer, the opinions of those who have had experience with ether both as a priming agent and as a factor in increasing the value of low-grade fuel, become distinctly valuable. THE AUTOMOBILE would welcome any ideas on this subject, as they would assuredly be of value to a large body of automobilists who refuse to put their cars in dead storage in spite of the vigorous onslaughts of Jack Frost.

Removing Shellacked Hose

Editor THE AUTOMOBILE:—If you know of anything that will remove a hose that has been fastened on with shellac will you kindly publish it in THE AUTOMOBILE.

Niagara Falls, N. Y. R. N. PATTISON.

—If you have an old hose the best advice would be to cut it off and put a new one on, because you will find that even after you have got it loose it will crack when you attempt to slip it off the metal connections. On the other hand, if you have a hose connection that is fairly new, take an old hacksaw blade and run it along an emery wheel to take off the teeth and then thin it down a little more at one end. This will be very flexible and by its aid and with the assistance of what alcohol you can work beneath the rubber with the hacksaw blade you can probably work it loose. If you once get it started the rest will come easily.

Cleaning Buick Cylinders

Editor THE AUTOMOBILE:—Could you tell me through the columns of THE AUTOMOBILE how to clean the cylinders of my model 14 Buick? Also how to fix it up for the winter.

Birdell, Pa. J. NORVIN HATFIELD.

—The Buick two-cylinder opposed motor is of the horizontal type and would seemingly present problems that would render it difficult to clean. This is not the case, however, as it can very well be scraped through the valve cover plates in the same manner as would be pursued with a vertical motor. The plates are taken off and scrapers of various shapes used until every point has been reached. To do a thorough job, however, with any motor the best way is to take it down and remove the cylinders. When this is done there will be no difficulty in reaching every point. If you are not going to run the car during the winter it will require but little attention. It would be a good plan to enamel the motor if the old enamel is worn off and to apply a coat of cylinder oil to all the exposed bright parts. Some oil should be injected into the cylinder and the motor turned over by hand once or twice to keep the cylinder in good condition during the winter.

If you are going to use the motor during the winter the compression should be tested by noting the resistance to turning the motor over by hand or by trying the car on various hills to see if the climbing powers are what they should be. If not, the cleaning of the cylinder and the grinding of the valves will be enough to restore the power in most cases. Clean out the old oil from the reservoir and replenish with new. Clean the spark-plug points. Tighten all the loose nuts throughout. Look at all water and other connections to see if there are any leaks. If there are, remove them by replacing gaskets. Try the ignition system after the plugs are clean and the wiring has been inspected, taking careful note that the batteries are of the proper strength. If any trouble develops it will probably be in the connections. These are a few points which must be noted. Others will occur in looking over the car for in a model as old as this there are sure to be some parts that are worn and which will have to be replaced.

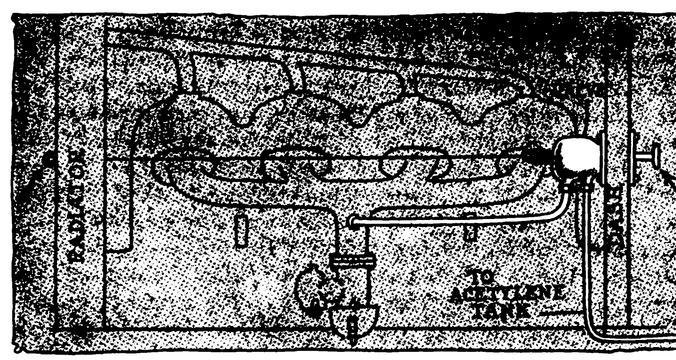

Fig. 2—Priming device for use with acetylene suggested by reader

Mounting of Front Wheels

Editor THE AUTOMOBILE:—Would you please give me the following information in regard to front wheels?

1. When one is standing looking at the automobile from the front what is the angle or degree at which the wheels are tipped, approximately?

2. Why is this done and what good is it?

3. Looking forward are the front wheels pointed straight ahead, and why?

4. Looking forward are the front wheels toed in a little toward the center, and what for?

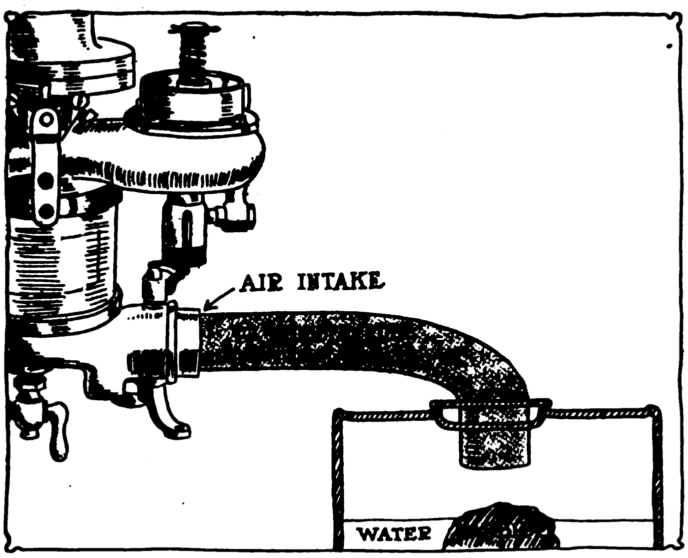

Fig. 3—Easy starting device which has been used with success in many garages

5. This last question is per the sketch, Fig. 1, as though the wheels pointed to a point away off in the distance.

Hartford, Conn. HARRY ALLEN.

—1. At about 3 degrees to the vertical.

2. This is done to minimize the shocks that are carried up to the hand steering wheel. As may be seen in Fig. 1, there are two ways shown in which the front wheels may be mounted. In the right view the line through the center of the steering knuckle is parallel to the line through the center of the wheel. In the left view the line through the wheel meets the line through the steering knuckle at P. the point at which t he wheel has contact with the ground. The difference in the two mountings will be apparent from a minute's study. Where the two lines do not intersect there is a small arm A representing the distance between the two parallel lines. Any impact between the wheel and an obstacle produces a turning moment about the steering knuckle which will be equal to the product of the force multiplied by the arm. Where this arm is zero, as it is when the two lines intersect at the point of contact between the tire and the ground, there can be no moment and hence no shock transmitted to the steering wheel from a straight-on contact with any object.

3. They are pointed straight ahead. That is the distance between the front ends of the two wheels is the same as the distance between the rear. If it were not so the tires would be rapidly worn away as they would be pusheed over the road and would not roll perfectly.

4 and 5 are answered under question 3.

Automobile Axle Conditions

Editor THE AUTOMOBILE:—Few owners of automobiles realize the important part that the rear system plays. In fact, most owners think that it is only a minor part of the car and that so long as the engine runs smoothly they are running their car under ideal conditions. This is largely due to the fact that most parts of the engine are reciprocating, while those of the axle are rotating. The former causing knocks; the latter causing almost any kind of a noise from a rattle to a groan.

How many buyers of cars today realize the importance of the rear housing? Few at least are ever posted as to their weak-

2—We must consider the brakes, which should always be powerful enough to hold the car and at the same time not powerful enough to grab or slide the wheels. I am inclined to think that most brakes are too powerful and consequently increase the tire cost. In the selection of any axle the greatest of care should be exercised to get away from the grabbing spoken of before and also the rattle which sooner or later will occur. A heavy lining should be used on all contracting brakes to protect the brake shoe from excessive heat, thereby causing the paint to crack off.

Internal expanding brakes are not advisable in that they are not accessible should the lining wear and begin to roll, neither can they be gotten to easily enough to insure proper lubrication on the operating bars.

The bearings should be of such a type that they can be easily taken up. This not only applies to the wheel, but also to the differential and pinion-shaft bearing. All bearing retainers and carriers should have a ground fit so that they are forced about .001 or .002 of an inch, according to the load they are to carry.

If the bearings are of the radial or cup-and-cone type they should by all means have line contact, of course. They should have a load factor of something like 300 per cent. in order to insure them against certain sudden shocks which occur from time to time.

If the buyers of cars will consider the above carefully they may save many hours of trouble and perhaps many dollars.

Wyoming, O. J. E. BRANSON.

Correct Way to Adjust Schebler

Editor THE AUTOMOBILE:—In THE AUTOMOBILE for October 24, and also in an issue of some months ago, you gave instructions for adjusting model L Schebler carbureter. Your instructions for adjusting low speed were to turn needle valve to the right until closed. Then to turn to the left about a turn and a half.

After having failed to adjust a new model L by these instructions, I got from the Schebler company a copy of their instructions. Their instructions for adjusting low speed were—after closing needle valve—to turn to the left from four to five turns. I tried this method of adjusting and found that it worked satisfactory on my carbureter.

Little's Mills, N. C. J. P. LITTLE, JR.

The Best Non-Freezing Solution

Editor THE AUTOMOBILE:—Would you please tell me the solutions that are commonly used in preventing the water from freezing in the radiator.

Detroit, Mich. CARL SCHNEIDER.

—In the issue of October 24, the question of non-freezing solutions was fully taken up and the merits of all the solutions was explained. A digest of the remarks in that issue follows:

—There are three well-known anti-freezing compounds which have been used extensively and which have proved themselves to be valuable for this work. They are alcohol, glycerine and calcium chloride. Besides these there are many others that are good, but they nearly all have some drawbacks that prevent them from being as useful as would otherwise be the case.

About the most popular of all the solutions to use in the motor is the alcohol. Wood alcohol or denatured may be used. The cost is small; denatured alcohol may be purchased for 60 cents per gallon and the price of wood alcohol is about the same. The advantages of alcohol are that it is very easily handled and that there is no action on the metallic parts of the circulating system.

When using denatured alcohol the freezing point will be different. In tabular form for temperatures between 5 above and 20 below zero Fahrenheit, the denatured alcohol solutions will be as follows:

Freezing Point	Denatured Alcohol	Water
+ 5 degrees Fahrenheit	24 per cent.	76 per cent.
0 " "	29 " "	71 " "
— 5 " "	32 " "	68 " "
—10 " "	34 " "	66 " "
—15 " "	37 " "	63 " "
—20 " "	40 " "	60 " "

Glycerine possesses many characteristics which would seem to stamp it as the ideal non-freezing agent. The boiling point is high and, as will be seen in the diagram Fig. 7, does not change the boiling point of the mixture regardless of the percentage added to the cooling water. Glycerine reduces the freezing temperature materially when added to the water, but does not do so as rapidly as wood or denatured alcohol.

When reducing the freezing temperature to such an extent that the water will not freeze in a cold climate it is necessary to add so much that the water tends to become gelatinous and for this reason it has been mixed very often with wood or denatured alcohol in a very successful attempt to combine the merits of the two. When glycerine alone is used the mixtures that are required for different temperatures will be found in the following table:

Freezing Point	Glycerine	Water
+28 degrees Fahrenheit	10 per cent.	90 per cent.
+15 " "	30 " "	70 " "
+ 5 " "	40 " "	60 " "
0 " "	48 " "	52 " "
— 5 " "	54 " "	46 " "
—10 " "	58 " "	42 " "

When the glycerine and alcohol are used together they are used in equal quantities. This mixture, which is purely mechanical, has not as great a tendency to rot the hose connections as a pure glycerine solution would have. It has more water in it than would the latter and is thus more free to pass through the radiator and other parts of the circulating system without doing harm. On the other hand, there will be less alcohol in this solution than there was in the pure alcohol solution and the result of this is that there will not be so much evaporation and necessary replacement of the cooling fluid after the motor has been run for a time. The glycerine and the alcohol are stirred up together and added to the water in the following proportions:

Freezing Point	Mixture	Water
+20 degrees Fahrenheit	15 per cent.	85 per cent.
+15 " "	20 " "	80 " "
+10 " "	24 " "	76 " "
+ 5 " "	27 " "	73 " "
0 " "	29 " "	71 " "
— 5 " "	30 " "	70 " "
—15 " "	32 " "	68 " "

We now come to calcium chloride, $CaCl_2$, and water. This compound has been recommended by many and is very good, although it has its dangers in the difficulty of securing the chemically pure article. In buying the calcium chloride for use in the cooling system of an automobile the crude article costing about 10 cents a pound should not be purchased. The chemically pure article costs about 25 cents a pound and is very satisfactory. The objections to the use of the material is its tendency to set up an acidic action in the radiator. Chloride of lime, which should be kept out of the radiator, is often a constituent of the commercial calcium chloride and care must be used in getting the chemical from a reliable concern who will guarantee the purity of their products. With the calcium chloride solution the percentages are given by weight instead of volumes as are the other tables:

Freezing Point	Calcium Chloride by Weight	Water by Weight
+10 degrees Fahrenheit	15 per cent.	85 per cent.
+ 5 " "	17 " "	83 " "
0 " "	19 " "	81 " "
— 5 " "	21 " "	79 " "
—10 " "	22 " "	78 " "
—15 " "	23 " "	77 " "
—20 " "	25 " "	75 " "

His Alcohol Evaporated

Editor THE AUTOMOBILE:—The writer has read your articles on Experience of the Automobilist in Cold Weather.

The latter part of December, 1911, I filled the radiator with 1-3 alcohol and 2-3 water, and thinking I was absolutely safe in not having my radiator frozen, I left the car out frequently.

For a week or so I had no trouble with my radiator freezing, but one very cold evening about the first of January I left the car in front of my house as usual, and when I came out and started the engine, I found the pump and radiator frozen solid.

I made a test of the solution that was left in the radiator, and found about 5 per cent. of the alcohol left in the water, this, of course explains why it was frozen.

New York City. D. L. MOORE.

—This is a natural experience and one which is to be expected when using any of the alcohols. It is really necessary to use a hydrometer with an alcohol solution in order to note the changes in specific gravity on account of the evaporation. The specific gravity of the mixture when the alcohol is first added should be noted and then at frequent intervals samples may be drawn off and should any change be noticed alcohol should be added until the solution is restored to its former condition.

In THE AUTOMOBILE for October 24 this problem was taken up along with many other considerations of the cooling problem in winter months. An instrument which was particularly adapted for telling the freezing point of a mixture was described. It may be stated that this was simply a hydrometer that was scaled off to read in freezing points instead of specific gravities.

Self-Starter for Ford Car

Editor THE AUTOMOBILE:—Please advise me what self-starter is practical for the Ford car.

Tolu, Ky. V. HARTON.

—Practically any of the acetylene starters could be fitted to your Ford car with very little expense. There are many of these on the market that give entire satisfaction selling as low as $10. They are connected to the acetylene supply and have attachments which fit on the top of the cylinder in place of the priming cups. The gas is controlled from a valve on the dash which admits a supply of gas to the cylinders and fires the charge when the ignition is switched on. One of the spring starters which automatically spin the motor until it starts could be fitted.

Although it would be well within the realms of possibility to install an electric or air system, these two would cost you so much that the two above systems would probably be the only ones to consider. The spring starter has the advantage of starting the motor while on dead center and the acetylene the advantage that in case the motor fails to start for some reason at first you will not have to get out and wind it up.

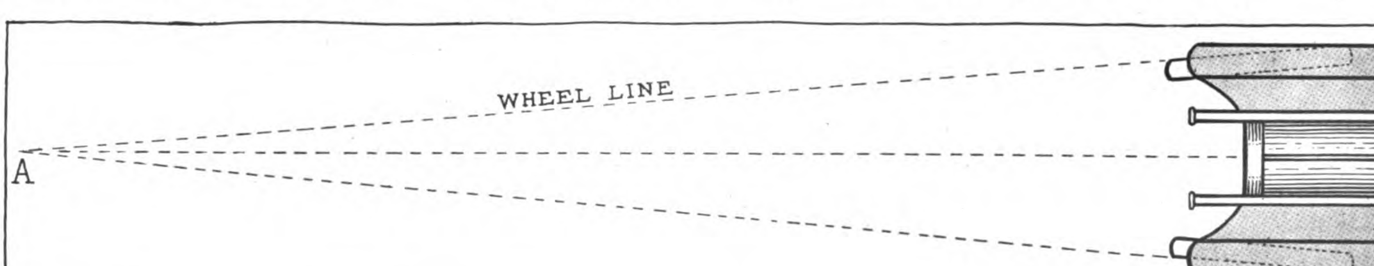

Fig. 4—Improper condition of the wheels. When this is true the tire wear is exceedingly rapid

The Annual Model

WHETHER the annual model is for better or for worse is still an unsettled question with automobile makers. Many of them imagine they have settled the question, but when their conceptions on the matter have reached the final analysis it is evident that they still desire many of the advantages that accrue from the annual model. There are some makers who would like the public to understand that they are opposed to the annual product because by such a course the impression is spread broadcast that their models are sufficiently perfected and an annual overhauling of them is not necessary to keep them in the forefront.

At the present time the American automobile is not a sufficiently perfected machine to warrant the elimination of the annual model. There are nearly twenty unsettled designs in connection with our automobiles. The question of self-starters is so far from its final form that many makers will have to change from season to season before an unchanged product has been evolved. To-day the ignition system is not in its last and final stage. In Europe the majority of the manufacturers are fitting a single magneto without any auxiliary system such as battery or dry cells. In America the concerns using the magneto as the only system are so few as to constitute a hopeless minority, yet it is almost a safe statement to make that within five years one single system of ignition will suffice just as one carbureter, one oil pump, one water pump or one clutch does to-day.

American automobile makers are not settled, in fact, far from it, on the question of rear axle construction. All of them are looking into the question of reducing the unsprung weight of the axle, some are introducing worm drive instead of bevel drive and others are making numerous changes. These questions will have to be wrestled with for years to come. The history of Europe in such matters will be repeated in America.

It is true that the annual model has worked some ills, but many ills have been attributed to it for which it has not been responsible. If the annual model has been responsible for different concerns adopting different accessories, that has been purely a business proposition with such houses. The annual model has been blamed for the landslide towards the acetylene starter of last year, which form of starter has again gone out so prominently since then. Granted that it played its part in this field it cannot be denied that **the sooner an accessory is conclusively proven unsatisfactory the better.** It is much preferable to have such a decisive verdict reached within 12 months than to require 36 months to get it.

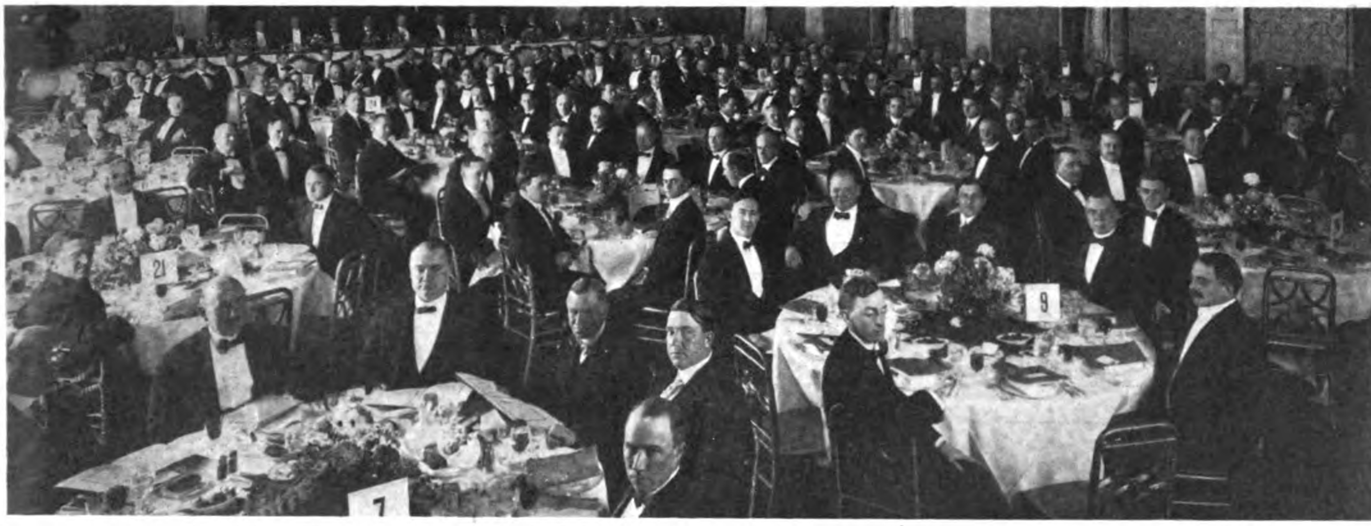
So long as automobile shows are continued so long will it be necessary to have the annual model. If the annual model is discontinued and cars exhibited at the 1913 shows are the same as those seen at the 1912 shows, then the public will stop attending shows, and the show will surrender its mammoth advertising value.

It is difficult to see why certain concerns are opposed to the annual model when in the same breath they acknowledge that they must continue making changes in their present models. So long as these changes are frequent, as they will be for some years to come, it will be necessary to adopt new models, new series, new numbers—it really makes little difference as to what the particular nomenclature is.

To the buyer it will facilitate matters if there is some symptom of similarity in the time when these are announced. There must always be a cleaning up of one model and a beginning of the next, so far as the factory is concerned; and when it comes to the dealer it will be necessary for him to announce his new number, new series or new types to his clièntele. If the dealer makes such announcement to his own injury that cannot be helped. He is his own keeper and is responsible for his own deeds.

It is unjust to tie to the annual model abuses in the business that are due to other causes. It is quite impossible to consider the annual model as responsible for the business system a dealer has in his salesroom. A good dealer will be a good dealer in spite of annual series or types; and a poor dealer may only find in the annual model an excuse for the failure of his business.

It must be acknowledged that the early announcement of the annual model has worked an injury due to the apparent disrupting of the selling field when the warm days of spring are coming and sales should be greatest. Often these stoppings of sales have not been as great as imagined, but they form a by no means negligible factor.



Gathering of 250 members and guests of the National Association of Automobile Manufacturers at the banquet held at the Hotel Pontchartrain, Detroit, Mich.

Heads of Industry Meet as N.A.A.M. Holds Its First Big Mid-Year Convention at Detroit

Manufacturing and Selling Corporations Are Represented and Hear Speeches and Discussions on Various Subjects, As Experts Deal with Pertinent Topics During 2-Day Session in the Capital of the Automobile Industry

DETROIT, MICH., Nov. 16—The first mid-year convention of the National Association of Automobile Manufacturers was held at the Pontchartrain Hotel November 14 and 15. It is doubtful if the association ever held a more successful meeting, in the light of the large number of prominent manufacturers who were present, the fund of valuable knowledge which was imparted, the important business transacted and the results accomplished.

The convention was opened Wednesday, November 13, with a meeting in the afternoon of the executive committee of the association, composed of W. E. Metzger, president; S. D. Waldon, W. C. Leland, R. D. Chapin and Hugh Chalmers, Detroit; W. T. White and L. H. Kittridge, Cleveland; Alfred Reeves, New York; H. H. Rice, Indianapolis; G. W. Bennett, Toledo, and S. A. Miles, Chicago.

However, it was not until Thursday morning when the general sessions commenced that the greater number of the members arrived.

This day was taken up with the reading of various authoritative papers and discussions, while in the evening the Detroit members tendered to those from out of town, and to other invited guests, a most enjoyable banquet in the auditorium of the Pontchartrain. About 250 attended the affair, and in addition to the many interesting speeches a variety of entertainment was provided. A. E. Larned, former president of the Detroit Board of Commerce, acted as toastmaster, while at the speakers' table were Henry Ford, Hugh Chalmers, W. E. Metzger, H. B. Joy, Thomas Henderson, L. H. Kittridge, R. E. Olds, H. O. Smith, Hal Smith, James Keena, George T. Moody, L. W. Goodenough, J. C. Wetmore, E. B. Boyd, Nat Duke, and J. N. Willys.

On Friday morning several more papers were presented, and in the afternoon an important conference between leading representatives of the railroads and the members brought the actual business of the convention to a close.

A number of the visitors remained over until today in order to visit some of Detroit's many interesting automobile and parts factories.

The Detroit Committee on Arrangements for the meeting was composed of William E. Metzger, Flanders Motor Company; Hugh Chalmers, Chalmers Motor Company; S. D. Waldon, Packard Motor Car Company; R. D. Chapin, Hudson Motor Car Company; W. C. Leland, Cadillac Motor Car Company, and H. W. Ford, secretary, Chalmers Motor Company.

The first speaker on the program at the opening session on Thursday morning was S. A. Miles, general manager of the National Association, who outlined its past work, its present objects and its future. He explained the reasons for holding the convention at this time when manufacturers are not busy with shows. Meetings held during the show season do not furnish the members a suitable opportunity to get together, to know each other and to ascertain what is going on in the association and in the world of automobiling, and to get out of the association the full benefit of the advantages it offers.

In his talk, Mr. Miles considered the history of the association for the special benefit of the newer members. The association was organized November 10, 1900, at the first show held in New York. The first executive committee meeting was held on December 3, 1900, and the body was incorporated May 4, 1904. The industry was then a mere dot in the world of commerce. There were about a dozen manufacturers, a few experimenters and a few importers.

Mr. Miles traced the course of the National Association during the days when the Selden patent was in force. Although the association never had any connection with either the licensed or unlicensed faction, and had in its ranks members of both sides, it was the victim of circumstances, and with the formation of the two rival bodies, commonly called the licensed and the unlicensed associations, it became a house divided within itself, though it did not fall. Since the reversal of the court decision and the abandonment of the licensed association, the National Association has regained much of its former strength, although it is not yet, as it once was, the sole representative of the trade.

Relations of N. A. A. M. and A. L. A. M.

Another body, known as the Automobile Board of Trade, has been formed, and much of the work of the two organizations now existing is duplication. It is hoped that the two can be consolidated, as there is much sentiment in that direction at present.

"No matter whether this can be accomplished or not," said **Mr. Miles, "the removal of the barrier between the two classes of members and the return of the National Association to power was the signal for results which plainly show the inevitable consequences of co-operation.**

"Our freight department backed by the members and the influence of a united industry became a real power and its value increased tenfold. Our commercial vehicle committee became so active that its work is among the most important we have done. Our show committee jumped into the breach and headed off threatened opposition in New York. The membership committee has added nineteen members to the roll, so that we have now 105 upon the list, by far the greatest number in our history. **Our work became once more aggressive and creative. We have done more good in the last 18 months than in the 7 years preceding."**

Mr. Miles touched upon the work of the good roads committee and on the association's co-operation with the A. A. A., the most notable result of which has been the securing of the appointment of a joint committee in Congress to take up the policy of the federal aid to the good roads movement. The association has been instrumental in the prevention of the passage of freak and discriminatory laws against automobilists and in the enactment of sane registration statutes.

The general manager further reviewed the work of the traffic department, the co-operation with the Manufacturers' Contest Association, the adoption of standard warranties, truck standardization activities and show work. He closed by saying, "The association, like the trade it represents, is stronger, richer and better than ever before; hence we have reason to believe that we shall continue to be more useful with every new year of our existence."

The general transactions of the convention resolve themselves into six principal divisions, namely: general business, traffic considerations, commercial vehicle work, yearly model discussion, selling problems and manufacturing. These divisions will be taken up in the order named.

Much of the business of the executive committee was of a general nature. Three were admitted to membership, swelling the total to 105. These were August Becker, Lippard-Stewart Motor Car Company, Buffalo; F. D. Waggoner, General Vehicle Company, Long Island City, N. Y.; and H. S. Miller, Lauth-Juergens Motor Car Company, Freemont, O.

The association will conduct a local show at Pittsburgh to fill a vacancy on the local show circuit caused by the inability of the two local organizations there to agree upon an exhibition in which the united trade may take part. The association is also in communication with the director of exhibits at the Panama-Pacific Exhibition and contemplates the taking over of and the allotment of the space which will be devoted there to the display of automobiles.

The commercial vehicle committee returned a resolution to the executive committee opposing an open-air motor truck show, it having been suggested that such an exhibition be held in the summer or fall of 1913, either as an experiment supplemental to the regular mid-winter show or to take the place of the latter after this winter. It was argued that such a show would give opportunity for the display of trucks in operation and of loading and unloading devices, but the predominance of opinion was that there are enough shows already, and that to introduce a big exhibition between April and December would tend to prolong the show season throughout the year, with its attendant disorganization of the factory forces.

Because of the cancellation of an agreement which formerly existed between the Manufacturers' Contest Association and the American Automobile Association as regards the running of contests, the National Association signified its willingness to appoint a committee to co-operate with the contest board of latter. Up to the time of the formation of the M. C. A. the National Association took an active part in the control of contests, and this is practically a step in the reverse to that policy.

In view of the soaring price of gasoline, the advisability of taking steps toward bringing about legislation to remove the ban upon the wholesale manufacture of wood alcohol for fuel purposes was discussed. It is stated that this fuel could be manufactured and profitably marketed at 10 cents a gallon, and many car makers and dealers feel that the association should act to relieve the ban which was placed upon the promiscuous manufacture of wood alcohol at the last session of Congress.

Although little is heard of the National Association in connection with good roads work, nevertheless its influential activities along this line have brought about many improvements in our national highways. The association has a good roads committee of which R. D. Chapin is chairman.

Mr. Chapin, in treating the subject of good roads, said in part:

"Some 8 years ago the association first interested itself in good roads work. It appealed to your executive committee, even then, that eventually touring was to become much more common in this country than abroad, where the finest of roads obtain. We knew that good roads were bound to come here, but our aim has been to hasten their construction, to help shape the legislation, both state and national, bearing upon highways, and to study the best types of roads for motor car travel.

Automobile a Road-Building Factor

"As each of you well know from your experience, our ideas have changed greatly in the past decade. The use of the roads by the tremendous number of motor cars that we all have produced has revolutionized the art of road building. It has given a great impetus to the making of permanent and continuous arteries of traffic. This very construction has in turn stimulated to a great extent the use of our product. **It has always been my opinion that the future expansion of our industry is in a great measure proportionate to the improvements in the roads of every state. We have each found that where the highways were good, automobiles were used in large and increasing numbers.**

"Two years ago your committee became convinced that from then forward the automobile user was perhaps the strongest factor, outside of the farmer, in the securing of good roads legislation. We therefore, in conjunction with the American Automobile Association, organized a Good Roads Board, composed of R. P. Hooper, president of the A. A. A.; A. G. Batchelder, chairman of the Executive Committee; G. C. Diehl, chairman of the Good Roads Committee; S. D. Waldon, representing the Automobile Board of Trade; C. J. Butler, representing the Motor and Accessory Manufacturers Association, and myself, representing the association. Our purpose was to co-ordinate the good roads work of the manufacturers and the users, bringing to bear the enormous influence of the organized body of users.

"Through the initiative of the National Good Roads Board the first Federal Aid Convention ever held in this country took place in Washington in January last. It was a notable gathering, country-wide in the complexion of its attendance, and including men who are leaders in the movement in their respective states.

"The concrete results of the convention was a resolution adopted by Congress, providing for a joint committee of House and Senate to take up the Federal Aid question in its

entirety, and to evolve a concise proposition. This joint committee now consists of five members each from the Committees on Post Offices and Post Roads of the two branches of Congress. With this committee we shall have much to do from this time on.

"Briefly summarized, the plan is for a comprehensive system of national roads to supplement well organized state systems, which shall include inter-county, market and township roads, with adequate provision for upkeep and a gradually improved form of construction.

"It is the belief of your committee that until we secure the construction of highways that will be permanent in the character of their roadbed, all roads will be much more expensive to maintain than should be the case. **We therefore say frankly that in favoring all highway construction, we hope the time is not far distant when the main arteries at least will be of some permanent construction that will need practically no attention for years after being laid. The government can do more to bring about a universal permanent highway construction throughout the country than any other agency. Hence, another reason for our campaign for national highways and Federal Aid.**

"National, state, county or township highways which bear the brunt of transportation, according to their particular uses, should be the ones first to receive consideration. Main township roads would have first call on the town; in like manner the principal county roads should first be built; the same idea holds good in selecting the roads of a state, and finally, those highways which serve in a national or inter-state manner, demand the Federal Government's primary recognition.

"Summarizing our efforts, let me say that we are endeavoring, through the user, to create highway departments in states that have none; to let the motor car owner pay his just proportion of taxes, these taxes to go into the respective highway funds; to secure federal aid and federal supervision of the inter-state roads, and to hasten as much as we can highway construction in every county in the United States."

The standard warranty which has been adopted by the National Association for both pleasure cars and commercials has been quite generally used by the members of the organization, but not unanimously. In this connection, S. A. Miles said: **"That the standard warranty is sound has been demonstrated by the fact that we have never heard of a case in which a manufacturer or a dealer suffered serious loss through its use."**

Freight Service Discussed

To urge its unanimous adoption, A. L. Pope, of the Pope Manufacturing Company, Hartford, Conn., prepared a paper entitled, "Why all Manufacturers Should Use the Standard Warranty." This was read by L. H. Kittridge, of the Peerless Motor Car Company, Cleveland. **Although advocating the use of the warranty, the paper took the stand that the car maker should not refer so much to the warranty which his product carries as to the service which he can give should anything happen to it. He should not expound so loudly that he will give free repairs, but he should so build his machines that there will be no repairs needed whether free or not.**

Ever since the organization of the Traffic Department of the National Association in 1908—4.5 years ago—no event in the movement of automobiles has escaped its attention. Through the efforts of this department most satisfactory results have been obtained in assisting manufacturers, and hence, indirectly dealers and car owners, to move their cars to their destinations.

One of the most important matters considered was that of freight car service, and to cope with this during the coming winter the N. A. A. M. has decided to instal a branch traffic department in the city of Detroit which will be opened by J. S. Marvin, who is head of this department of the association work, at the earliest moment. **The work of this department from the Detroit office will cover probably from Buffalo east and will consist in following every freight car filled with automobiles from the time they leave the various factories in this territory until they reach their destinations, when every effort will be made to get them hurriedly unloaded and immediately returned to the factory. By such a follow-up plan it is hoped that all available cars for automobile railroad shipment will be used to the fullest capacity.**

It developed in the discussion between the automobile manufacturers and the freight representatives of the various railroads who attended the conference at the request of the manufacturers, that the shortage of cars was often due to carlessness on the part of teh automobile manufacturer as well as neglect on the part of the railroads. **It developed that automobile manufacturers not infrequently get freight cars delivered to their factory shipping platforms and hold them 3 or 4 days and perhaps longer before making a shipment.** The railroad companies in Detroit by investigation discovered this abuse. Loss of time in this way is equally as disastrous as delays on the part of the railroad company holding the empty cars at the point of delivery after the dealer has taken the vehicles out of them.

Marvin Talks on Transportation

But the railroad freight representatives announced that their respective roads are doing much to relieve the situation by new cars, some of the companies having recently placed orders for as many as 500 new ones.

The railroad representatives who were present at the conference were A. B. Atwater, assistant to the president, Grand Trunk Railway System and General Manager of the lines in the United States; E. B. Boyd, assistant vice-president, Missouri Pacific Railroad and the Soo lines; G. C. Conn, vice-president and traffic manager, Pere Marquette Railroad Company; J. S. Bartle, assistant traffic manager, Atchison, Topeka and Santa Fe Railroad Company; Nat Duke, assistant traffic manager, Delaware, Lackawanna and Western Railroad Company; and W. C. Rowley, general freight agent, Michigan Central Railroad Company.

In speaking on the subject of traffic as it applies to the National Association, Mr. Marvin outlined the workings of the traffic departments of the large industrial concerns as a comparison. **He placed the amount of freight earned by the railroads of the country on shipments of automobiles from all factories at not less than $6,000,000 per year and explained how this expenditure should be supervised.**

"The question of service," said Mr. Marvin, "is of vital importance to the industry. When the railroads fail to operate on accustomed schedules or when they are unable to keep pace with the manufacturer of any article within reasonable limits in the supply of freight cars, the situation is about as serious as could be imagined. The conversion of finished goods into cash is interrupted.

"When industries in general find it difficult to secure sufficient freight cars, the situation is rendered all the more difficult for the automobile factories, for when a car shortage occurs, shippers of other articles gain the use to a large extent of the automobile cars.

"Such a car shortage exists in this country today; the railroads are right now taxed to the limits of their resources in handling the exceptionally large crops and a heavy movement of traffic of all kinds. The return of freight cars to the home roads is difficult of enforcement, and when it is considered that the observance of this rule is all that the automobile industry has to depend upon for the shipment of its goods, the real aspect of the situation confronting us is apparent. To shippers of other articles which can be loaded in ordinary box cars it does not matter so much if the cars they load are owned by the railroad furnishing them, but the automobile shipper hasn't this choice and must in the main depend upon the outlying railroads returning the initial lines' automobile cars."

The subject of Yearly Models was brought up for discussion, the principal speaker on the topic being H. O. Smith, Premier Motor Manunfacturing Company, Indianapolis, Ind.

Mr. Smith's address was entitled Yearly Models and in it he took a firm stand against such and attributed many of the present ills of the industry to annual models. He characterized the annual series or models as a barnacle which has fastened itself upon the industry.

Among the various injuries worked by the annual model

is that of factory expense in that each annual model, incorporating changes means the abandoning of jigs, tools and other equipment. There is also a factory loss in production because the workmen in the factory who have grown familiar with the production of the previous model produce at a lower capacity during the time required to familiarize themselves with the new job.

I am not sure that any particular changes made from year to year makes new buyers, an exception, however, being the addition of such an accessory as self-starters. **How many of the 990,000 automobile owners in the United States to-day purchase their first car because it was one of the latest models?**

One of the ills of the annual model is the early announcement, an example being a concern announcing in April, 1912, its 1913 model, this announcement being made before some of the Iowa dealers had a chance to even demonstrate their 1912 models to the buyers. These are the announcements that merely serve as signals to the buying public to stop buying 1912 models and wait until the full complement of 1913 models have been announced.

Yearly models cause unrest in factories. There is always a hurry. A hurry to complete the last of the old models; a hurry in the true room to get the jigs and tools ready for the new models, and other hurries.

The annual models can be charged with the second-hand car evil which has loaded itself on the industry.

Mr. Smith concluded his paper by presenting the fact that the new annual models or series do not actually create new business.

Following this paper one of the most heated discussions of the entire conference took place. The makers ranged themselves on both sides. Those who talked in favor of the annual model advanced the argument of style as a selling factor, whereas those opposed to the annual model centered their arguments around service rather than style.

The Multiplicity of Models

To the manufacturing branch of the automobile industry the address by G. W. Bennett, Willys-Overland Company, Toledo, Ohio, on the multiplicity of models belongs. Mr. Bennett advocated the concentration upon a small number of models, since the marked successes of the automobile industry will in the future lie in specializing, each plant making that which best fits its demands, and producing that model in the quantities to which its place in the automobile market entitles it.

To make several models in a factory which is equipped to make not more than one satisfactorily necessarily restricts the output of that plant and divides the energies of its engineers, its operative force and its selling force into several small channels, all of them considerably below par in efficiency because of such division.

The growth of the industry shows that the most prominent manufacturers have realized this and are catering to the class of demand which they can best supply. I believe that this development will become more marked, and that in a very few years each factory will limit its product to one model with perhaps several styles of bodies interchangeable on the chassis.

It may not always be possible for one manufacturer to profitably restrict himself to one chassis, but it will be possible, if more than one is considered necessary, to make a large number of the parts interchangeable, and only in this event would the production of two models be warranted or likely to be successful.

Furthermore, the subject of subsequent service is involved so much that where more than one model is built adequate service to the user is difficult and consequently seldom satisfactory, and without that satisfaction complete success is impossible.

Mr. Bennett pointed out that since the interests of the dealer are identical with those of the manufacturer, concentration of the manufacturer on a single model allows the dealer to focus his atention to this same single type, with his consequent better acqaintance with it and the methods necessary to sell it.

He said that it would be expecting too much to hope that the industry would be able to arrange production so that every company will prosper, but he stated that the association was in better shape to accomplish such a result than any other agency.

Two Papers on Selling

Chalmers and Benson Consider Problems of Marketing Cars

Extracts from Addresses Read Before the National Association of Automobile Manufacturers

On automobile selling, the manufacturers heard two able papers, one by Hugh Chalmers, Chalmers Motor Company, Detroit, who attacked the selling problem with which the car maker of today is confronted, and the other by E. R. Benson, Studebaker Corporation, Detroit, on territory and discounts.

Our selling problem, said Mr. Chalmers, may be roughly divided into two classes—first, those the solution of which can best be accomplished by the manufacturers as a whole working together; second, those in the solution of which each company must go its own way and find its own best methods. It is the first class, very naturally, that we should consider here.

We are led to the first problem worth our while to consider by the question What is selling? What constitutes a sale?

It seems to me that selling—selling a motor car, for instance—is something more than simply exchanging an automobile for a check or for so much cash. This may be merely a friendly transaction; or an exchange, fair or unfair, or perhaps a bit of charity or philanthropy. Selling, real selling, is the disposal of goods at a profit. Anybody can give goods away, but selling things at a profit is a job for good salesmen and good business men. Let us keep this point in mind.

Now, gentlemen, business exists for the net. It is a nice enough thing for those who like it to build up a great volume of gross business merely for the sake of talking about it, but the final test of success is in the net figures. The prime object for which we are all working, therefore, is to make money.

It seems to me that automobile dealers are of more vital importance to both the manufacturer and the buyer than is the dealer in nearly any other line of business. **The right sort of automobile dealer is harder to get than a good dealer in other lines**—that is why he is so vital to the manufacturer.

And, again, an automobile dealer is needed more by the buyer after the purchase than is the dealer in any other line—that is the public's vital interest. Both the manufacturer and buyer, therefore, are anxious to have a good dealer and to have him remain so. **A good dealer won't remain good very long unless he can make some money; unless his business will show a net profit. Either he will get out of the business, or he will simply drift along for a time, only to fail entirely in the end.**

Mr. Chalmers pointed out how over-production affects sales, how second-hand cars, weather, good roads and honest advertising have a good or bad influence.

Inasmuch as the apportionment of territory and the discount to be allowed the agents are much mooted questions, Mr. Benson's talk was very timely.

Territory, in one sense, he said, is the capital of the sales manager, inasmuch as out of it he has to obtain his results. The subject of territory, therefore, commands the deepest study and research; it demands that we should all have ready the best sources of information and the latest data to draw from; that we should have on hand statistics on population and wealth, late reports on manufacturing and other industries, reports on crops, on mercantile conditions, on the status of the markets of the country, as well as continual reports from our own traveling representatives, analyzing conditions from their points of view.

Mr. Benson believes that the discounts and divisions of territory, no matter to which class given, should all be controlled, systematized and agreed to by the manufacturer in order to insure his procuring the most out of the territory. He took up the consideration of the bonus or rebate plan and the system of graduated discounts by which the dealer commences at one rate and gets a greater discount in proportion to the amount of business he does.

Truck Committee Report

Revised Body Weight Allowance Scale Is Submitted

Scale of Demonstration Charges for Commercial Vehicles Lowered—Warranty Work Progressing

MR. WALDON presented reports of the work of the Commercial Vehicle Committee since the June 4 convention of the National Association and of the business transacted at the meeting of this committee November 6. As a result of its deliberations the association revised the scale of mimimum body weight allowances based on stake types, as adopted at the March meeting of the association. The revised schedule representing approximate averages of weight of all types of bodies commonly fitted to chassis of the different capacities follows:

Load Capacity, Pounds	New Body Weight Allowance, Pounds	Former Body Weight Allowance, Pounds
1000	600	500
1500	750	...
2000	900	600
2500	1000	...
3000	1050	700
4000	1200	800
5000	1350	900
6000	1500	1000
7000	1600	1100
8000	1700	1200
9000	1750	1300
10000	1800	1400
12000	1900	1600
14000	2000	1800
16000	2100	2000
18000	2200	2200
20000	2300	2400

The scale of demonstration charges for commercial vehicles which was adopted at the June meeting of the National Association was lowered. This was done because it was deemed desirable that the charges should bear a close relation to the actual normal cost of operation of the vehicles and that the rate per ton-mile of work done should decrease as the capacity of the unit increased. The new schedule is given:

Truck Capacity Tons	Approximate Average Cost Per Day	New Scale of Demonstration Charges Per Day	Former Scale of Demonstration Charges Per Day
½	.....	$10.00	$10.00
1	$8.50	10.00	10.00
1½	9.50	11.50	.....
2	10.50	13.00	15.00
2½	11.50	14.00	.....
3	12.25	15.00	20.00
3½	13.00	16.00	.....
4	14.00	17.00	25.00
4½	15.00	18.00	.....
5	15.50	19.00	30.00
6	16.50	20.50	30.00
7	17.25	22.00	35.00
8	17.75	23.00	35.00
9	18.25	24.00	40.00
10	18.50	25.00	40.00

Efforts made to ascertain the extent to which the standard truck warranty recommended by the National Association has been adopted by manufacturers have brought forth replies from sixty-four makers. Sixteen members and eighteen non-members have reported their definite adoption of the warranty and their intention to incorporate it in their new catalogs when issued. Nine other member companies and one non-member are in favor of the standard warranty and report that when they are manufacturing commercial cars on a sufficiently large scale to require a truck warranty they will probably adopt this one. Seven non-members favor the warranty and say they will adopt it if a majority of the makers do so. Three members and one non-member report that they have the question under consideration. **Opposition to it was found in only nine cases.**

With a view to rendering truck bodies more readily interchangeable between different makes of trucks of the same capacity rating, and to enable the body builder to make up stock bodies that can be mounted on any make of chassis on demand, the committee collected a large amount of data from truck manufacturers and from an analysis of this data recommended two standard frame widths which were adopted by the association.

These frame widths are 36 and 42 inches and frame lengths, also adopted, for distances back of the seat, are in multiples of 1-2 foot from 48 inches for the lightest package delivery car to 216 inches for the largest sizes of trucks. The committee's idea in making frames in multiples of the foot and 1-2 foot lengths is so that the number of frame lengths in common use on trucks of 1, 1 1-2, 2, 3 and 5-ton trucks can be reduced to fifteen sizes to meet all ordinary requirements even with short, medium and long wheelbases in each capacity. These would be made in 1-2-foot lengths from 8 feet to 15 feet. However, ten sizes from 9 to 14 feet will take care of all ordinary requirements.

These frame lengths can be made up to fit the two widths of frames—36 and 42 inches—and in any of the standard types of bodies desired. If these recommendations are adhered to by a majority of the truck manufacturers it will make the problem of supplying bodies much simpler for the maker of this part of the completed vehicl.

Three Papers on Truck Subjects Read

In addition to the report of the work of the Commercial Vehicle Committee since the last convention of the association in June, three papers dealing with truck and business vehicle subjects were presented during the course of the Detroit convention.

S. D. Waldon, Packard Motor Car Company, considered the relative business in pleasure cars and trucks:

On every side we hear the prediction that the motor truck business will be the big end of the motor car industry in a few years, said Mr. Waldon. We get it from newspapers; we get it from bankers, and automobile manufacturers believe it themselves. Undoubtedly many automobile manufacturers and their agents, too, have begun to look upon the truck as the vehicle which is going to carry the financial load of the pleasure car business.

Now, it is well worth while at this time to inquire carefully what justification there is for this prevalent conviction. Is the growth in the volume of the truck business not vastly overestimated, and has it not already been more than fully anticipated and discounted by manufacturing preparations?

A somewhat startling answer to these questions is found by a simple comparison of the present relation of the volume of truck business to passenger car business in the United States and the number of factories engaged in each branch of manufacture.

Carefully compiled statistics, which are very conservative, show that 652,000 passenger cars were registered in the various states last year. The same compilation shows that 25,500 commercial vehicles were registered in the same year. **On this basis there was one truck to twenty-six pleasure cars.**

The total estimated value of the passenger cars was, in round numbers, $812,000,000 and the total valuation of the trucks was $56,000,000. This makes the proportion of passenger car value to truck value last year approximately 15½ to 1.

Investigation shows the astonishing fact that there are about an equal number of factories in the country producing passenger cars and commercial cars. The numbers are variously estimated according to the ideas of different enumerators as to what constitutes an active manufacturing concern.

Probably as good a criterion as any is the number of makers who exhibited their products in each line at last winter's automobile shows at New York and Chicago. There were 111 different manufacturers of pleasure cars in the Garden, Palace and Coliseum shows and 101 exhibitors of commercial cars.

Thus we find that there are nearly as many companies competing for $56,000,000 worth of truck business as there are companies dividing among themselves the bulk of the $812,000,000 worth of passenger car trade. On an average the truck manufacturers had done a total business of about $560,000 apiece up to the beginning of this year and the passenger car makers a business of about $7,320,000 apiece.

State registrations for the first two months of 1912 showed

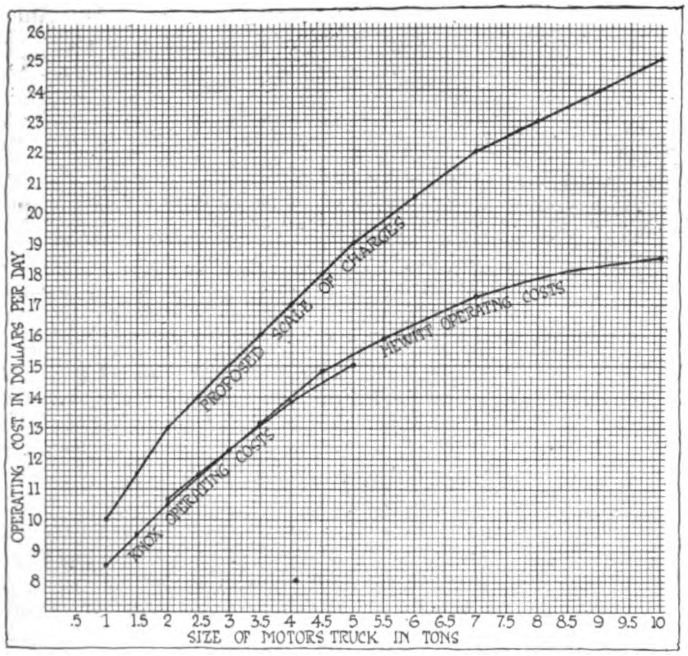


Chart illustrating average actual motor truck operating costs per day and scale of demonstration charges based on them as proposed by the N. A. A. M.

17,126 commercial cars registered, as compared with 342,439 passenger cars, or slightly less than 1 to 20.

There is no desire on my part to belittle the motor truck business, but in giving my personal attention to the work of the Commercial Vehicle Committee of the National Association some of these facts have come home to me with particular force, and it seems that a considerable number of persons have been carried away with enthusiasm over motor truck prospects and embarked in their manufacture without making any study of existing conditions and calculating the prospects of the future.

The cost of manufacturing and selling trucks is considerably higher proportionately to the volume of business done than the cost of manufacturing and selling passenger cars.

In connection with the consideration of truck matters, an address was delivered by M. L. Pulcher, Federal Motor Truck Company, Detroit, on the subject of the injudicious truck selling methods and their effect.

The necessity for disposing of product in order to realize on it and devote the money to payment of accounts and the continuance of manufacture, said Mr. Pulcher, is the root of numerous evils in the selling end of the business. There are two principal kinds, one originating with the factory and the other with the sales force.

The executives at the factory probably believe that theirs is the best truck built of its rated capacity and price, and they cannot see why the salesman should have any difficulty in selling it; consequently they press the sales force.

The first result of such factory policies is to realize the object—quick sales. If there were no other and adverse results such would become common practice, but the fact is they are going out of favor both with the truck manufacturer and the public.

The selling of trucks is not very different from the selling of other machinery, and it should be done on the same sound basis.

Mr. Pulcher took up the methods of sales from the salesman's end, discussing the fallacies of price-cutting and the various ways of arriving at charges for demonstration. The common fault of knocking the other fellow's product in order to make sales was discouraged.

David Beecroft, editor of The Automobile, discussed a subject of vital interest to motor truck manufacturers, in that he showed a situation with which the commercial vehicle manufacturer must cope and must remedy in order to make his product show up to its best advantage. Mr. Beecroft's subject was Transportation Delays at Railroad and Dock and City Terminals.

Of 287 motor truck and horse wagons checked at railway and steamboat terminals in the cities of New York, Chicago and Detroit it was discovered that these vehicles had an average delay of 11.3 minutes from the time they reached the proximity of the freight terminals until they reached the unloading platform and were ready to begin unloading or loading operations.

Figures taken of the length of time required for these 287 vehicles to unload or load showed an average of 27.3 minutes each, so that, roughly speaking, each vehicle waited almost half as long to get to the loading or unloading platform as it required to perform the loading or unloading. This loss of time cuts down the efficiency of the motor truck as well as that of the horse vehicle.

Of the three cities, New York, Chicago and Detroit, the last showed the least delay. Of forty-two vehicles checked in the city of Detroit the average delay at one railway freight terminal was 3 minutes and at another 4.4 minutes. This difference in time was due to narrower approaches at one than the other. Chicago averages better than New York in the reduction of time lost at terminal depots. **Of three leading Chicago freight terminals in investigations extending over three successive days, the average delay at one depot was 6.2 minutes per vehicle, at another 11.7 minutes, and at the third the amazing figure of 25 minutes.** In contrast with this are the figures taken from three New York City dock terminals based on observations extending over a similar period. In one the average delay was 9 minutes, at a second 10, and at a third 15.5. While these averages do not appear abnormally high, they invariably represent a high ratio with the time required to unload. This is demonstrated at one Chicago depot where the average delay was 25 minutes and the average unloading time 24 minutes, so that each vehicle waited longer to get the chance to unload than was required in the unloading. At another Chicago depot the average delay was 11.72 minutes, and the average unloading time 23.74 minutes, giving a delay-unloading ratio of 1 to 2. In New York, at one of the docks the average delay was 10 minutes and the average unloading time 19 minutes, which is more than a 1 to 2 delay-unloading ratio.

But all of the loss of time or delays at freight terminals, whether in connection with railroads or steamboat docks, is not due to lack of capacity—lack of system is a big factor in many cases.

One of the greatest obstructions to the reduction of delays at present is the driver of horse vehicle. He is generally in sympathy with the delays and often actively assists in causing them. Recent observation showed traffic jams in the city of Chicago, where 155 to 175 vehicles, mostly horse trucks, and some motor trucks, were held for 1 hour and 20 minutes. The blockade was finally broken up by mutual consent of the drivers, and was accomplished in fewer than 5 minutes. Many horse drivers make it a point of reaching the railroad freight yards and spending from ½ to 1 hour sleeping. They often miss their turn at the unloading platform, but are not disappointed in that they have accustomed themselves to doing but three trips or to carrying three loads per day, which allows of wasting a great deal of time, and they calculate on doing this.

The whole horse vehicle driver situation is so unsatisfactory that the dealer in motor trucks will have to give it his most careful investigation or he will meet with disappointment.

John C. Wetmore went straight to the point in his talk at the N. A. A. M. meeting late Thursday afternoon, using as his subject, "Contests as an Aid to the Automobile Industry."

He stated it as his opinion that the manufacturers must provide contests to make the news to enable the newspapers of the country to continue the generous treatment now given news of the automobile industry and stated that unless the makers came forward more liberally with entries for contests they would soon find themselves barred practically from the news columns of the country.

Mr. Wetmore said that from one end of the country to the other there was a war to-day against the amount of space given to motoring and he advised that the N. A. A. M. recommend to the A. A. A. the reclassification of great racing events and segregation of great classics for every class of cars, giving it as the opinion of the newspaper men that greater good would be done the industry by having the great events of the year each a star event in one locality instead of grouping many great events as at present.

He advocated the formation of local promoting associations such as New York has formed to promote track races, road races, hill climbs, touring events, exhibitions, orphans' day outings, and so on, these events being promoted by a stock company composed of all dealers with 50 per cent. of the profits to a sinking fund to cover possible future losses.

Truck Demonstration Charge To Be Lower

National Association Figures on Reducing Cost to Prospective Purchasers, Especially in Large Vehicles

Compilations of Knox and Hewitt Companies Used as Basis for Recently Adopted Scale of Prices

TREATING demonstration charges based on operating costs, the National Association of Automobile Manufacturers has compiled the following article and tabulations:

Theoretically, the cost per ton of motor trucking should decrease as the size of the truck increases, and logically, any schedule of charges for demonstrating motor trucks should bear a definite relation to the actual cost of operation and maintenance. Such charges should also be so fixed that the cost of doing a given amount of work will be less with the power vehicle than with horses and wagons.

The most elaborate tables of truck operating costs are those issued by the Hewitt Motor Company and the Knox Automobile Company. They agree closely in the average per diem costs of motor trucks from 2 to 5 tons' capacity. These costs are shown in the appended table in columns two and three, together with a schedule, in column four of uniform approximate average costs for all truck sizes. The costs are also plotted in the lower curves of the accompanying chart.

The work done by each size of truck is shown in ton-miles in column six. The ton-mile capacity of a truck in a working day is assumed to be the tonnage rating of the vehicle (column one) multiplied by its speed in miles per hour (column five) times one-half the number of working hours, that is 5. The miles per hour are the N. A. A. M. standard speed ratings. Five hours is taken as the total daily running time, as in general trucking service about one-half of the 10-hour day is consumed in waiting for loading and unloading and other delays.

Dividing the daily cost of operation by the ton-miles of work performed gives the ton-mile cost in cents shown in column seven. It is noteworthy that the rate drops gradually from the 1-ton size to the 5-ton size, and then gradually increases to the 10-ton size.

As nearly as can be calculated from information at hand the cost of doing work with horses is as follows:

COST OF TRUCKING WITH HORSES

Tons	Team (horses)	Daily Rate	Miles Per Working Day	Ton Miles	Ton-Mile Rate (cents)
1	1	$5.50	16	16	34.37
2	1	6.50	16	32	20.31
4-5	2	8.50	12	48-60	17.70-14.16
8-10	4	17.50	12	96-120	16.35-14.58

According to this table, based on statements furnished by professional truckmen, it costs twice as much to do work with horses as with motor trucks, even allowing only 5 hours' running per day for the power vehicle. The horse figures show the average maximum day's work for animals, but if the waiting time of the motor truck is cut down one-half by quick-loading methods its work capacity is increased one-half and the ton-mile rate decreased proportionately.

If it is conceded that the charges for demonstrating motor trucks should be higher than the actual cost of operation, it is found that a schedule one-quarter higher gives the scale shown in the dotted line in the chart, ranging from $10.62 a day for a 1-ton truck to $23.12 a day for a 10-ton truck.

As this is an awkward scale of dollars and cents, the scale shown in the solid line, ranging from $10 a day for a 1-ton truck to $25 a day for a 10-ton truck, has been adopted by the N. A. A. M.

The new scale is materially lower than the system of rates that has been in effect generally, the chief reductions appearing in the charges made for the larger sizes of trucks. These amount to as much as $15 a day for 10-ton truck demonstrations and range from that figure to a saving of $1 or more on the smaller sizes.

Big Men as Truck Drivers

Automobile trucks have created a demand for a new type of chauffeur, according to the officials of the Automobile School of West Side Young Men's Christian Association, Eighth avenue and Fifty-seventh street. It is the heavy man, with well-developed muscles, who can drive and care for his car and also load and unload, that will find himself much in demand.

This fact is emphasized by the present enrollment at the automobile school, where a great many of the students are men who have been sent to the school by business concerns that are using motor trucks. Almost without exception, the companies have picked big, muscular men.

A. W. Robinson, sales manager of the truck department of the Locomobile Company of America, in a letter to Edward L. Wertheim, Educational Director of West Side Y. M. C. A., voices the same opinion. Mr. Robinson says:

"I do not think the average chauffeur for pleasure cars will make the proper driver for a truck. One of the difficulties is going to be in getting men who will be able to operate and take care of the mechanical feature of the truck and willing to load and unload. For these men, however, there is going to be a big demand.

"We would be glad to have your opinion on this matter."

Inquiries were made by Mr. Wertheim to ascertain the average wages paid to motor truck drivers. Investigation showed the following average of wages:

Drivers of 1-ton trucks $18 per week.

Drivers of 3-ton trucks $21 and $22 per week.

Drivers of 5 to 7-ton trucks $25 per week.

The employment department at West Side Y. M. C. A. also shows this tendency for big and muscular men to drive trucks. Many business houses secure their employees through the Y. M. C. A. employment bureau.

"Send us a driver for motor truck, but he must be a big man," is the tenor of many letters received.

Tabulation Showing Operating Costs in Real Experience Compared With the New Scale

1 Truck Capacity (tons)	2 Average Operating Cost Per Day (Hewitt)	3 Average Operating Cost Per Day (Knox)	4 Approximate Average Cost (per day)	5 N. A. A. M. Speed Rating (MPH)	6 Ton-Miles Per Day, 5 Hours' running	7 Rate Per Ton-Mile (cents)	8 Scale of 125% of Operating Cost (per day)	9 Rate Per Ton-Mile (cents)
½				16	40		$10.00	25.00
1	$8.58		$8.50	15	75	11.33	10.00	13.33
1½	9.50		9.50	14	105	9.04	11.50	10.95

British Designers Aim at Increased Motor Efficiency

(*Continued from page* 1039)

ticularly well adapted to thermo-syphon cooling, the water pipe connections being of the simplest nature. In the case of the six-cylinder engine the cylinders are cast in two blocks of three cylinders each. As regards the valves, these are arranged on one side of the engine, giving an L-type combustion chamber, this type being held by most British makers to be the most satisfactory. The valve tappets and springs are inclosed by readily detachable doors. For the purpose of valve construction a special steel is employed having a high percentage of nickel and thus offering great resistance to over-heating and pitting. The inlet and exhaust valves are interchangeable. The crankcase of the four-cylinder engine have five bearings and the bushings in which the crankshaft journals run are white metal. The bolts which hold the bearings in place pass through the top of the crankcase so that the metal of the crankcase is held in compression instead of in tension. The lower part of the crankcase forms an oil sump only.

Another interesting feature is connected with the cooling, which is termed assisted thermo-syphon. With this arrangement the fan spindle is supported by the water inlet pipe, and the spindle of the fan is extended to the waterjacket carrying at its inner end a propeller, which, while it assists in driving the circulating water, provides sufficient clearance not to impede the circulation should the fan belt become detached.

The crankshaft, which has five bearings in the case of the four-cylinder engine, has seven in the case of the six-cylinder engine; it is constructed of the highest quality nickel chrome steel, oil hardened. The crankshaft, as well as the camshaft, bearings may be inspected by the removal of a pair of aluminum doors on the side of the crankcase.

Ignition is performed by a high-tension magneto. The armature is driven by a dog-coupling mounted on a shaft extending from the timing-gear casing, the design of which permits the fitting of independent dual ignition to the 20-horsepower car when required. The firing point is, of course, variable from the steering wheel.

The control of the engine is effected by a throttle lever and a magneto advance lever, both fitted above the steering wheel, in combination with a pedal accelerator.

For 1913 the following Napier motors will be constructed:

Horsepower	No. of Cylinders	Bore and Stroke
59.9	6	127 x 127
45	6	102 x 127
30	6	82 x 127
15	4	82 x 127

The engine has a bore of 82 millimeters by a stroke of 127.

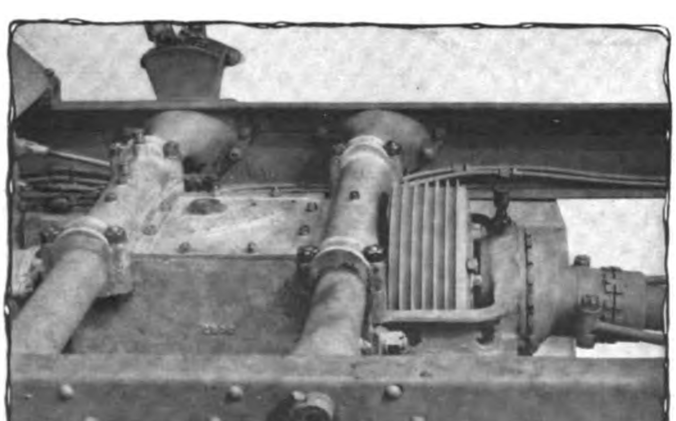

Fig. 11—Crossley gearbox attachment on the 1913 20-horsepower chassis

The Bosch high-tension magneto of the single order is retained, with variable control. Considerable attention has been paid to the lubrication, which is of the entirely forced-feed type. A rotary oil pump delivers oil to the bearings under pressure with a valve arrangement adjusted to regulate the amount of oil according to the speed of the engine, a relief valve being provided which prevents the oil rising above the maximum. This is obtained by a spring-loaded valve which returns any excess of oil to the sump. The oil-circulating pipes are outside of the base chamber, so that they are easily detached for cleaning, although every precaution is taken to filter the oil by means of gauze filters in the oil filling inlet, and in the chamber between the pump and the outlet pipes.

The carbureter is of the two-jet type, with rotating throttle valve and adjustable air shutter. It is fed gasoline under pressure, a small air pump being worked from the engine camshaft. As an instance of the care given to minute details, the air inlet of the pump is covered by very fine gauze to prevent the suction of any dust.

Another feature is that the exhaust pipe is carried down the front end of the engine, which prevents heat getting to the front seats, a particular advantage where the scuttle dash is employed. Fig. 1, showing the side view of the Napier chassis, clearly indicates the general arrangement of the whole.

With regard to the 15-horsepower model, the bore and stroke of the engine are 82 by 127 millimeters, with cylinders cast in pairs. The engine and gearbox are built up as a unit. It will be noticed that the flywheel is at the front end, and another feature is that the base chamber of the engine is not open to the gearbox or the clutch. Each of these component parts has its own oil chamber, the reason being that oil which was suitable for the engine was not satisfactory for the clutch, which is of the multiple-disk type. A cock is attached for the purpose of indicating by means of a rod the level of oil in the clutch chamber. When filled up to the necessary level, oil flows out of the cock, and denotes that the requisite lubrication is provided.

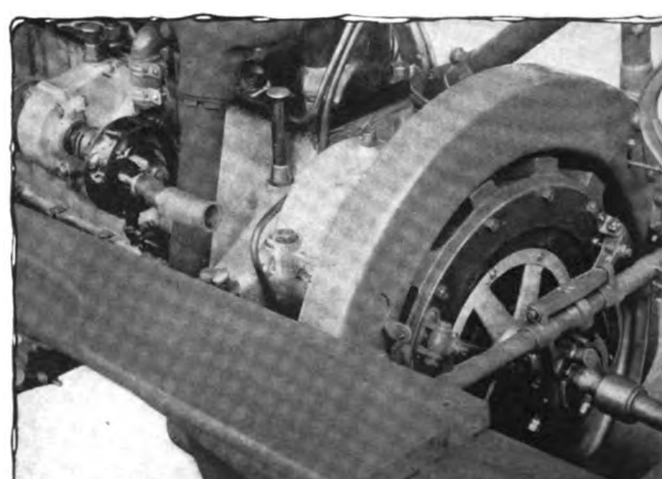

Fig. 12—View of the clutch and rear suspension of the Deasy motor

Spur gears are used for driving the camshaft and spiral for the magneto, which is of the single Bosch type. Cooling is on the thermo-syphon principle, and it will be noticed that there is an extra outlet immediately above the exhaust valves between the spark-plugs.

The Argyll program for 1913 comprises four types, that is, a 12-horsepower four-cylinder poppet valve engine henceforward to be called a 12-18 horsepower; a 15-horsepower model for colonial purposes fitted with a poppet valve engine: a 15-30 horsepower and a 25-50-horsepower sleeve valve model.

The 12-18-horsepower engine has the same bore and stroke dimensions, that is: 72 millimeters by 120 millimeters, but the exhaust and inlet valves are of larger diameter and consequently, more power is developed.

The 15-horsepower is similar in most respects to the 12-horsepower, but it has 80 millimeter by 120 millimeter cylinders cast in pairs. Thermo-syphon cooling in conjunction with an efficient ball-bearing fan insures proper cooling.

Briefly, there is in the Argyll engine, Fig. 17, a single sleeve, and this sleeve has a combination movement produced by an oscillation and a reciprocation, thus any point upon the sleeve describes an ellipse upon the cylinder wall. The sleeve has five ports in its upper end and the cylinder has six ports. Three of these ports are for the inlet of the gases and three for the exhaust; meanwhile the central port in the sleeves serves alternately as an exhaust and an inlet port. The exact shape and size of these ports has been decided after considerable experiment.

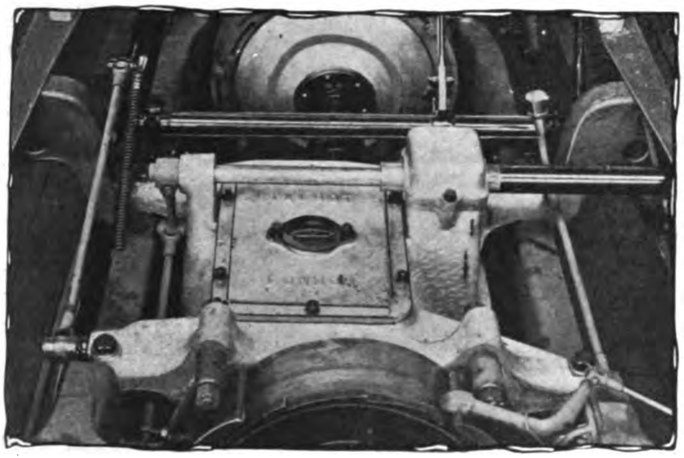

Fig. 13—Talbot gear box and brake mounting with long spiral back-spring

The crankshaft has three bearings, the journal diameter being 45 millimeters. The bearings from the front end have lengths respectively of 82 millimeters, 64 millimeters and 80 milllimeters, while the crankpins have the same diameter as the shaft and a length of 50 millimeters. The short crankwebs have a width of 54 millimeters and a depth of 24 millimeters, and the center webs have the same width and a depth of 40 millimeters. Thus, there is very little chance of whip. The crankshaft has at its flywheel end an oil throw collar of 64 millimeters diameter and at the forward end a double V collar to act as an oil throw. The pistons have a length of 102 millimeters and are provided with three rings. The small ends of the connecting-rods are well drilled to provide lubrication, and rather substantial bushes are fitted. The sleeve driving shaft has a diameter of 32 millimeters and 50 millimeters. A silent chain, 1.5 inches wide, is employed to revolve the shaft. Outside the chain pinion and close up against it is a ball journal bearing to take the pull of the chain, and at the rear end of the shaft a double ball thrust is provided to take up the end-thrust of the spiral gears.

There is one small alteration that has been made in the sleeve-driving mechanism. A small hole has been drilled through the wall of the plunger into the interior so as to break any small vacuum that might otherwise be caused.

The oil pump has gears of about 25-millimeter pitch diameter and a tooth width of 12 millimeters. The port which supplies the pump with oil is a long drilled hole at the bottom of which is a small ball valve contained in a removable seating and one would expect that the fact that the pump has to draw its supply of oil from a point some 10 inches beneath it might lead to trouble. The oil pump is held up in place onto a conical seating by four studs bearing upon a square flange so that the pump is readily removable. There is a chamber on the side of the crankcase containing a float and needle indicator for ascertaining the oil level, and the top of the needle passes through a small fitting having a spring lid which normally holds the needle down. Lifting the lid makes the needle free to slide. The under side of the crankcase has longitudinal ribs to assist in carrying away the heat of the oil used for lubrication as shown in Fig. 17.

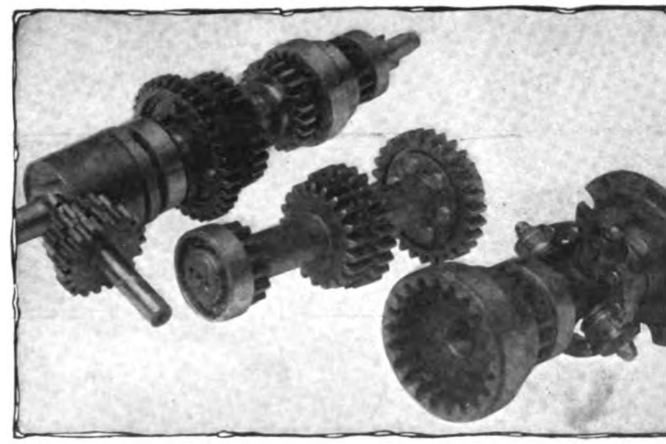

Fig. 14—Three gearshafts and gears in Crossley change-speed set

There is another piece of detail work in connection with the spiral gear. Immediately above the oil pump can be seen the main oil way and there passes through this opposite to each spiral gear a drilled set-screw. In this manner a stream of lubricant is continually thrown upon each of the four gears so that there is not much possibility of trouble here.

As in the earlier engines neat ebonite caps cover the ignition plug pockets and prevent the accumulation of dust or dirt which might easily occur otherwise. The cylinder head is, of course, separate, as in the Knight engine, and this leads to certain convenience in the matter of the cleaning of the cored out portion and also facilitates cylinder boring. The manifold pipes through which the mixture passes to the cylinder are water-jacketed.

The Briton engine has cylinders 68 millimeters in diameter and a stroke of 120 millimeters. The cylinders are cast in pairs and a water space is allowed between each pair of adjacent cylinders. The pistons are perhaps shorter than is usual with this class of engine, being only 70 millimeters long and but three rings are provided, one of which serves to keep the wristpin in place. The crankshaft is 38 millimeters in diameter and the bearings are ample, especially the rear one against the flywheel, which has a length of 90 millimeters. There is, however, what appears to be an unnecessary overhanging of the flywheel, though it will be seen that the crankshaft is strengthened hereabouts to prevent the possibility of whipping.

The camshaft is a solid one and it is considerably enlarged at the bearings, which are three in number, so that the whole shaft can be pushed in endwise, the cams passing easily through the bushes. There seems to be no objection to this method of construction and it certainly makes for cheapness.

The valves have a diameter of 32 millimeters and it will be seen that the guides have hollow interiors. The hollowing of the guide presents an advantage in this wise: When the guide of the exhaust valve becomes slightly worn the escaping gas which usually is the cause of much annoying hissing noise would be checked in its flow by expanding into the pocket of the guide.

The valve tappets are furnished with fiber insets to deaden the noise of contact with the valve stems and at their lower ends the tappets have rollers 25 millimeters in diameter. The valve mechanism is inclosed to silence the action.

The construction of the Deasy engine in no way differs from the usual Daimler-Knight motor, which is, as usual, fitted with the Daimler vibration damper at the front end of the shaft. The object of this arrangement is to damp the vibration, which is caused when the periodicity of the crankshaft, considered as a spring, corresponds with the rate at which it receives impulses from the pistons. It will be realized that, however stiff the crankshaft is made, the fact that the drive is taken only from one end tends to allow the front crank throw, under explosion pressure, to twist very slightly forward relative to the flywheel. This twisting effect is, of course, intermittent and is due to the natural elasticity of the crankshaft, which when the impulse is

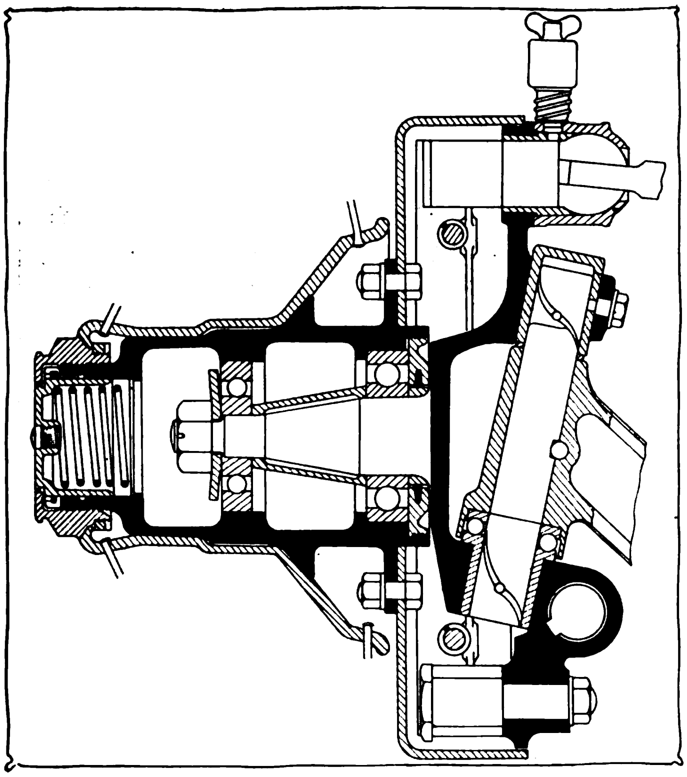

Fig. 15—Steering knuckle and front wheel mounting on the Argyle

removed, springs back to its normal position. When, however, the piston impulses correspond to, or become multiples of, the natural period of the crankshaft, considered as a spring, then the amplitude of torsional oscillation is considerably increased. The vibration produced in this manner which is found on all six-cylinder motors, and also on four-cylinder ones to a less extent, is produced only at certain definite engine speeds. In order to overcome this trouble the special vibration damper referred to above is fitted to the front end of the crankshaft, and consists of a supplementary flywheel not positively attached to the crankshaft, but driven through what is practically a multiple-disk clutch. When the periodic vibrations commence, the inertia of this frictionally driven flywheel causes it to slip, thus preventing the synchronization of the various disturbing forces and causing the vibrations to neutralize one another.

The carbureter fitted by the Deasy company is one of its own design, and as shown in Fig. 7. The throttle is of the butterfly type and works in a water-jacketed casing. Immediately below this is the casting which forms the float chamber, and through the center of which is the passage containing the jets. These jets are mounted on a hollow cross-bar which is cast integral with the float chamber and within the central passage is a valve so arranged as to slide freely in a vertical direction.

The float is of the annular type and surrounds the jet chamber, as shown in the section. It operates the needle valve contained in the upper part of the carbureter, which also carries a plunger, by means of which the float may, when necessary, be agitated. The gasoline is led directly to the inlet valve and need not be detached so long as the upper part of the carbureter remains attached to the inlet pipe. The whole of the bottom half, containing the annular float, jets and the sliding valve, is instantly detachable by partially undoing a couple of thumb-nuts.

The arrangement enables the engine to accelerate with extreme rapidity. As mentioned above, this is brought about by the inertia of the valve, which causes it to lag behind momentarily when the throttle is opened suddenly. This means that for a fraction of time a very powerful suction is placed upon the pilot jet, thus giving the engine a very rich mixture, which is gradually weakened as the valve rises. This prevents any tendency to fire back into the carbureter when a sudden opening of the throttle takes place.

The New Star Company is producing five models for the coming season, two of which are entirely new and have engines with long stroke, as shown in the table and in the description which follows:

Horsepower	Cylinders	Bore and stroke
10/12	4	80 x 120 millimeters
12/15	4	80 x 120 millimeters
15.9	4	80 x 150 millimeters
20.1	4	90 x 150 millimeters
23	6	80 x 120 millimeters

The 10-12-horsepower model has en bloc cast cylinders and the unit method of combining engine clutch and gearbox. It has a strong two-bearing crankshaft, a camshaft driven by spiral gear, magneto ignition, thermo-syphon cooling and force-feed lubrication.

The 12-15 model is the same as that known last season as the 12 horsepower. The cylinders are cast in pairs and the units are carried separately in the frame. There are four speeds and a reverse.

The 15.9 horsepower and the 20.1 horsepower are entirely new models and their design is practically identical.

The cylinder diameter of the 20.1-horsepower motor is 90 millimeters and the piston stroke 150 millimeters. The connecting-rod is of about usual proportions, that is, about two and one-sixth times the stroke, though it has the appearance of being a little longer than this. As the cylinders are off-set, the pistons can be short, and they are in fact only a trifle longer than the cylinder diameter. The crankshaft journals have a diameter of 50 millimeters and are three in number. The cylinders of each pair are very closely placed, there being only the smallest film of water between them. This fact, though a little objectionable from the point of view of the cylinder, is advantageous to the crankshaft and enables a strong compact shaft to be employed. Thus the central web of the crankshaft is not inclined to suit the crankpin as is sometimes necessary and it has a depth of 35 millimeters. The center lines of the crankpins fall immediately below the cylinder centers, so that the thrust is evenly distributed over the journal and this is a very desirable feature. The camshaft has a diameter of 30 millimeters and the cams are cut solid upon it.

The ignition of the Star motors is by the high-tension Bosch system. This follows the usual English practice which is decidedly away from battery, dual or double systems. High-tension ignition alone being fitted. Lubrication is by means of the splash system.

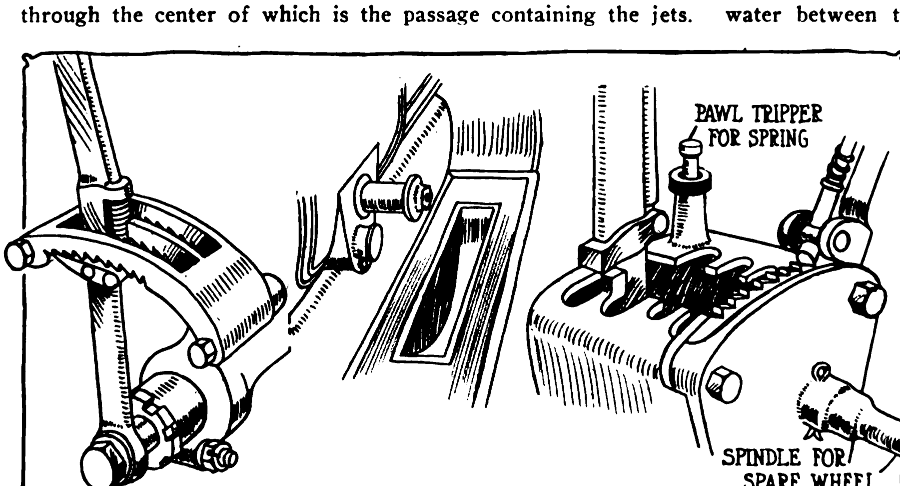

Fig. 16—Daimler change speed gate and exterior and interior view of spare wheel spindle on Talbot cars

Three of the Daimler models have been retained for the sea-
1 1913 and two added, as given in the following table:

Horsepower	Cylinders	Bore and Stroke
20	4	90 x 130 millimeters
26	4	101 x 140 millimeters
38	4	124 x 130 millimeters
30	6	90 x 130 millimeters
39	6	101 x 140 millimeters

'rom the above it will be seen that the 80 by 130 has been ninated and will be no longer constructed. The 90 by 130 etained at a slightly increased price. The four-cylinder 101 130 will in future be made with a stroke of 140, and is praclly a new model. The 38-horsepower four-cylinder 124 by remains as last year. The six-cylinder 80 by 130 will not be le in the future, and in its place a six-cylinder 90 by 130 is stituted. The large six-cylinder model 101 by 140 is retained. stroke of this engine has been increased to 140 millimeters. s regards the 20-horsepower model, only minor alterations e been made in connection with this type. With the engine ight improvement has been effected in the lubrication ar- gement. As is well known the Daimler lubricating system onnection with the Knight engine consists of a multiple- ger pump which supplies filtered oil to troughs placed be- h the connecting-rods, these troughs being adapted to be d or lowered to suit the varying speeds of the engine.

ie new 26-horsepower model, bore 101 by 140 stroke, has, as l, the cylinders cast in pairs, but they are placed out of cen- vith regard to the crankshaft. The amount of this désaxé ig is 13 millimeters.

iother modification of the previous Daimler practice con- in setting the magneto and pump shaft parallel with the cshaft instead of being set across at the front and driven oiral gearing. In the new model silent chain drive is em- d.

e Clement Talbot Company is not introducing any new in its engines for 1913. Four models will be constructed llows:

orsepower	Number of Cylinders	Bore and Stroke
12	4	80 x 120 millimeters
15	4	90 x 140 millimeters
20	6	80 x 120 millimeters
25	4	101 x 140 millimeters

e following are the chief characteristic features of all models: Cylinders cast in pairs; all valves in line and interchangeable; camshaft operated by spiral gearing; pump for lubrication and water circulation; Bosch dual magneto ignition with variable control; leather-faced cone clutch; gearbox with four speeds and reverse; bevel drive; inclosed driving shaft from gearbox to back axle, and semi-floating live axle.

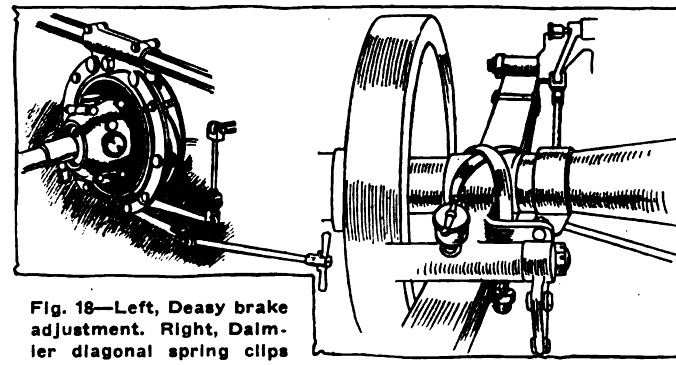

Fig. 18—Left, Deasy brake adjustment. Right, Daimler diagonal spring clips

Engine lubrication of the Talbot cars has received most careful attention. The oil pump is of the rotary type and driven vertically by spiral gearing from the camshaft. The circulation is indicated by a gauge fitted onto the dashboard. For the distribution of the oil the crankcase is furnished internally with a pipe from which branches are taken to each crankshaft bearing. The crankshaft is drilled, through which the oil passes to the big bearings. Fig. 5 shows the six-cylinder crankshaft with connecting-rods attached.

The large use of cone clutches and four-speed gearsets is well brought out by a study of what a few of the representative makers are doing in this line.

No change has been made in the leather cone clutch on the Daimler, but the universal joints of the clutch and gearbox have been made with large bearing surfaces. The gearbox now has the layshaft driving gears at the front end, as with last year's cars, the sliding universal joint of the fore and aft shaft is placed behind the gearbox. The reason for this practice being that the travel of the sliding bearing is thereby reduced while the action of the universal joint is further reduced by the placing of the rear springs beneath instead of above the axle. Another advantage of this arrangement is the smoother driving

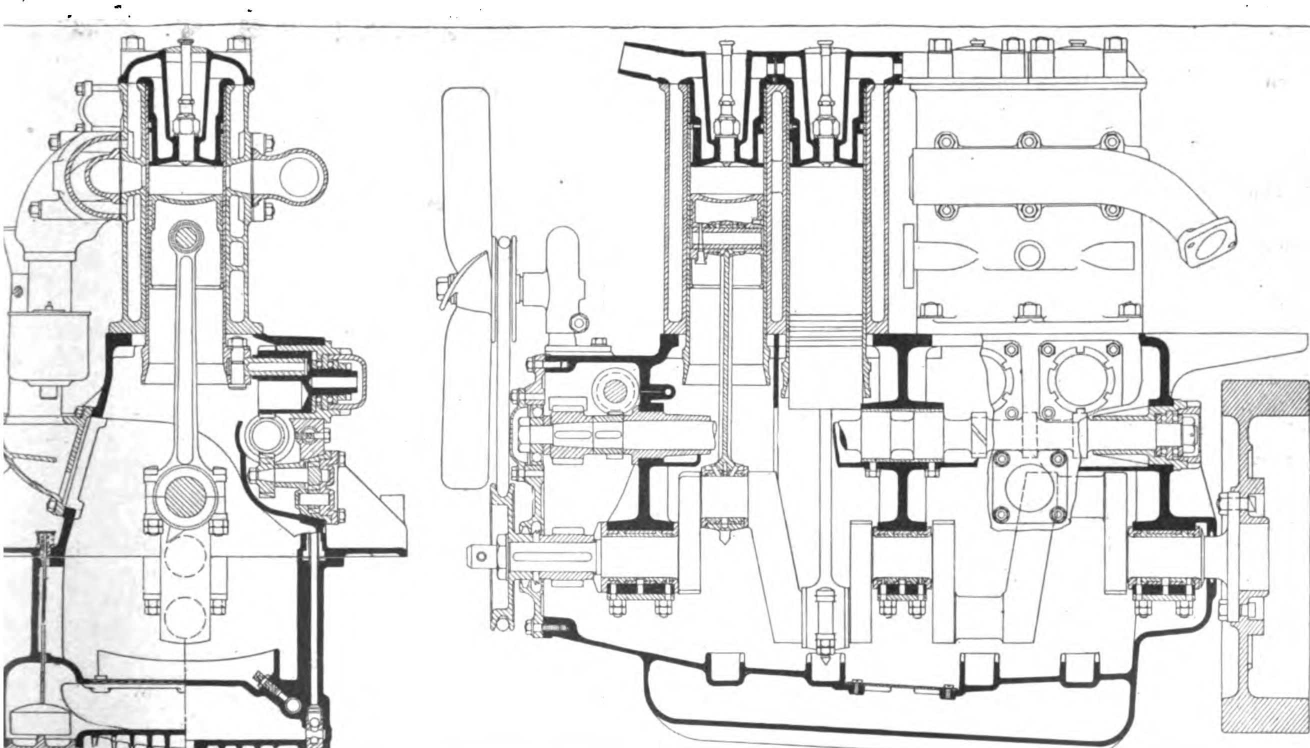

Fig. 17—Transverse and longitudinal sections of the Argyle sleeve motor continued for 1913 without radical change

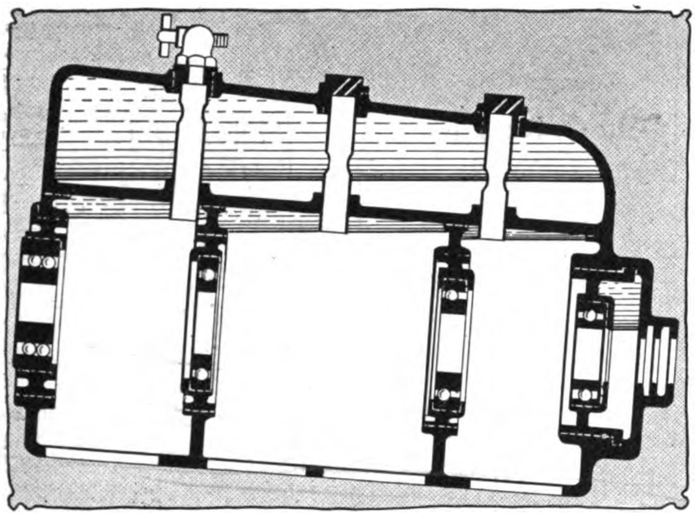

Fig. 19—Oryx crankcase, showing the unique oiling system

and braking action and the lowering of the frame height from the ground.

The Wolseley clutch is of the multiple all-steel disk type and thirty plates are employed inclosed in an oil-tight casing. A split-plate universal joint is fitted between the clutch and the gearbox. The gearbox, particulars of which have already been given, is provided with four speeds. The front end is centrally bolted to a double cross-stay which also carries the brake shaft and clutch levers. The rear end of the gearbox is bolted to the channel section frame cross-member. A three-joint suspension is thus provided.

With the Humber cars the clutches are of the leather type and are so inclosed within the flywheel that they are not affected by dirt or moisture. An aluminum cover plate is provided, and the clutch works entirely in oil.

On the Swift car the clutch is a leather cone with springs under the leather to allow of easy engagement. The four-speed gearbox is actuated by gate change, the gear wheels themselves being supported on short castellated shafts mounted on suitable load ball bearings, a special feature of this box being the design of the layshaft as all the gears on the latter are separate units.

The Arrol-Johnston clutch is of the floating-plate type, a plate gripped between two others, the whole running in oil. The clutch is readily adjustable and as the rotating part is very light, gear changing is rendered an easy matter. The clutch cross-bar is held in adjustable bearings, and it is claimed that this method of mounting is responsible for an absence of all chattering of the clutch pedal—a source of annoyance in some cases.

The Adams clutch is of the leather-faced cone type with a somewhat unusual spring arrangement embodied in the design. The spring, instead of being placed behind the male clutch disk is in front of it. The clutch shaft is hollow to receive the crankshaft spigot and at its inner end there is a disk screwed on and locked to act as an abutment for the spring. A cap screwed over a cylindrical extension of the flywheel and female clutch member serves to adjust the compression of the spring, and a ball thrust bearing is situated within the cap. There is, moreover, a special locking ring from the adjusting cap and this is provided with a set-screw to receive it. A ball thrust bearing is provided on one of the forks of the flexible coupling which comes into play when the clutch is disengaged, a coiled spring keeps the two thrust disks of the bearing in position. There is a well-designed universal coupling to permit some flexibility between engine and gearbox, and a De Dion type of joint is provided in which a malleable cast iron pot is provided with case-hardened steel working surface held in place by pegs and a steel back plate. The clutch pedal operates through a link and bell crank lever.

Belsize combines the clutch and gearbox, the whole forming one unit. As regards the clutch, this is of the metal-to-metal variety and both members are of cast iron. The diameter of the male member of the small end of the taper is 10 inches and the width 2.375 inches. A very stiff spring is used, having six coils of round steel .375 inch in diameter, and a good ball thrust bearing is provided to come into play when the clutch is disengaged. The spigot bearing from the clutch is 1.25 inch diameter and 4.125 inches long and has a phosphor-bronze bushing.

The Vauxhall clutch is of the multiple-disk type. There are thirteen driving plates and twelve driven, adhesion being secured by a helical steel spring 3.5 inches in diameter. The shaft which transmits the drive from the clutch plates to the universal coupling is 1.5 inches in diameter, and attachment is made at both ends by means of taper and key. The flywheel, to which the outer casing of the clutch is attached, has a diameter of 16.25 inches and a rim width of 3.25 inches. The spring load on the clutch spring can be varied by revolving the cup-shaped casting in one direction on the other, subsequent locking being performed by screwing up the ring-nut. A ball bearing supports the forward end of the clutch shaft.

The New Star clutch is somewhat interesting in that it is a leather cone clutch completely incased at the back. This casing permits the use of oil. Some of the advantages of the plate clutch are present and, as will be remembered in the diagram recently published, the leather cone clutch is not at all failing in popularity. It is believed that clutches of this type are to be far more numerous than in the past.

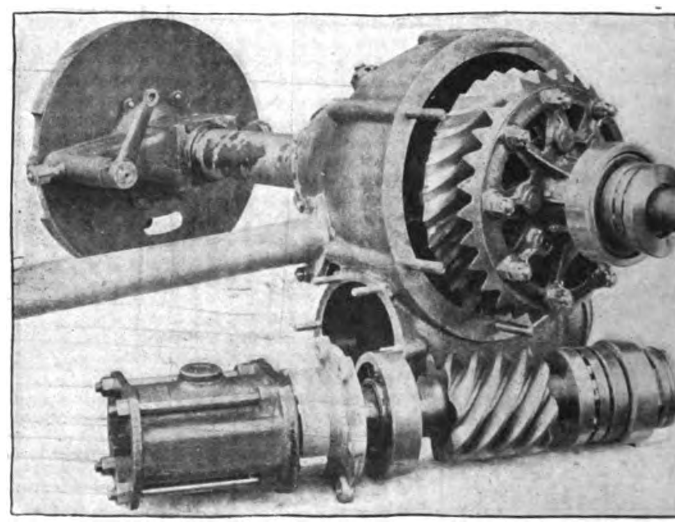

Fig. 20—Worm drive on Napier 15-horsepower car

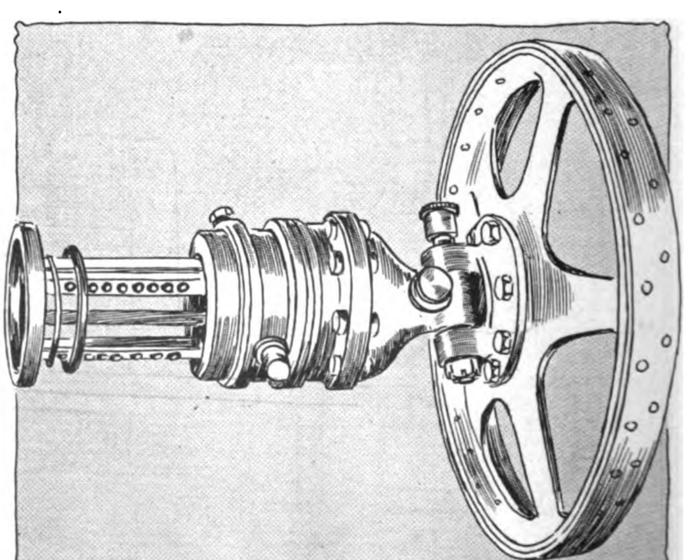

Fig. 21—Leather-faced cone clutch in use on the Germain-Knight

The Argyle clutch is of the plate type and has forty-five plates. A peculiarity of the design is that there is no extension of the crankshaft to support the clutch shaft, but this shaft is supported in a ball bearing held in the flywheel.

Three speeds and a reverse are provided on the Briton car with a direct drive on the highest speed. A peculiarity of the construction at once noticeable is the fact that both plain and ball bearings are in use; the short shaft which first receives the drive of the engine has a plain bearing with a phosphor bronze bush; the spigot bearing is likewise a plain bearing, while the remaining bearings are ball bearings. Of the gears on the secondary shaft two are cut solid with the shaft and the remaining two form a part of a single forging.

A three-speed gearbox is applied to the Bell cars. This gearbox is characterized by the arrangement of a sliding sleeve on each shaft, which has the effect of throwing the layshaft completely out of gear when the direct third is engaged.

The Maudslay Company last year was conspicuous in the use of a chain-driven gearbox. A return has this year been made to the orthodox spur-gear type. The worm drive to the back axle has also been dropped by a return to the bevel, Fig. 23.

The whole of the Napier change-speed mechanism is fitted within the gearbox, gears being changed by a partial rotative and transversal movement of the cross-valve and sliding sleeve. An innovation with regard to gearbox is the fitting of ball bearings in the place of rollers, which have hitherto been used.

Rear axle, brake, torque rod and other chassis construction details have been given special attention by the English engineers as the following points will illustrate:

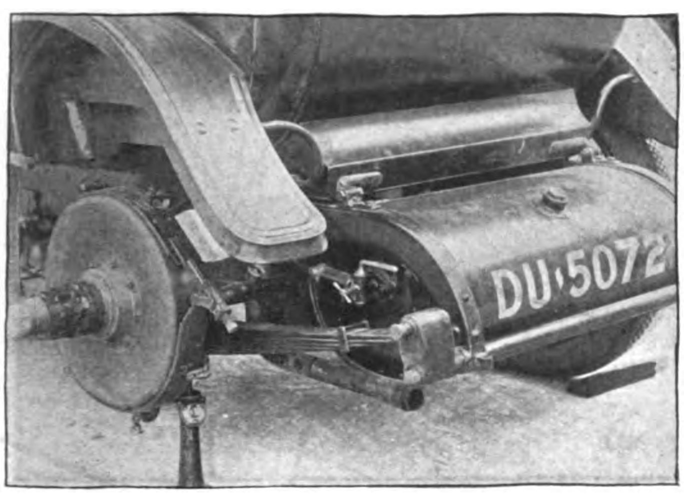

Fig. 22—Rear view of new Daimler 26-horsepower car

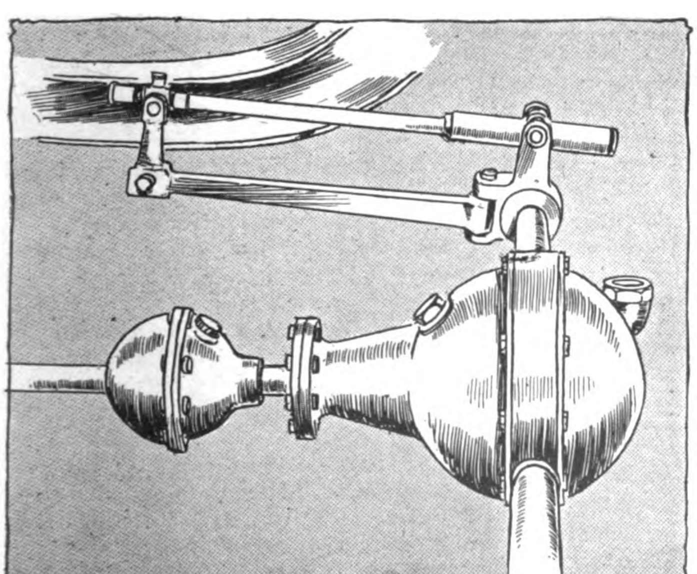

Fig. 23—Simple construction a feature of Maudslay rear axle

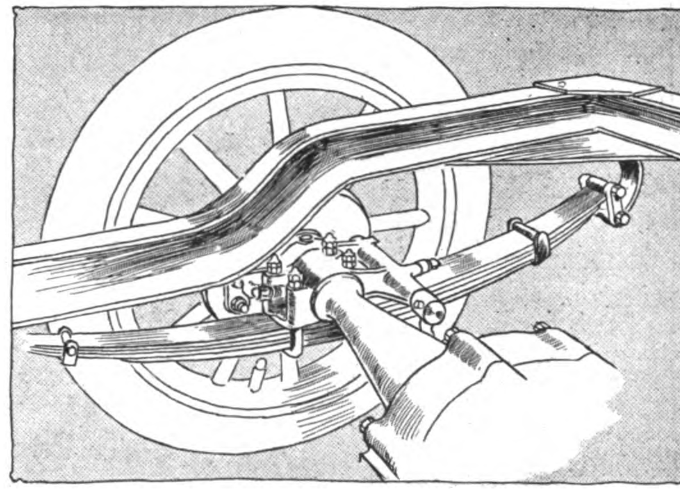

Fig. 24—De Dion returns to the underslung form of rear suspension

The Deasy foot brake is on the propeller shaft. The brake shoes are supported on a stout cross tube, carried by the side-members of the frame. This is generally a better system than that of carrying the brake shoes on studs secured to the gearbox. A ready means of adjustment is provided and is operated by means of a handle which extends slightly beyond the side-member of the chassis, so that this operation can be carried out in a moment without taking up any floor-boards or getting underneath the car. The handle actuates a screw which forms a link connecting the two halves of the brake together, and by which they are equally and simultaneously operated.

The rear brakes are internally expanding and are expanded by cams carried on brackets formed in one with the back axle casing. They are applied differentially by a compensating device which is connected to the hand lever.

The gasoline tank is carried under the scuttle dash and feeds by gravity, the lever of the pedal being arranged at such a height to give sufficient hold to feed the carbureter on the steepest incline.

The rear axle on the B. S. A. has an overhead worm. The road wheels are provided with a single ball journal bearing, thus a small proportion of the load is taken on the axles, which, however, are 30 millimeters in diameter. The permanent hubs are driven through a key and the Rudge-Whitworth type detachable wheel is fitted. Lubrication for the ball journal bearing is provided for by the removal of a screw plug, the lubricant passing through small drilled holes in the axle and thence into a shallow groove in the permanent hub. As the hub is fixed by means of a single key only, the groove must necessarily coincide with the small drilled hole in the shaft.

The return to the bevel drive by the Maudslay company indicates the improvements that have been made as regards the means for rendering the bevel gear more silent in action. Just as the Knight engine compelled manufacturers and designers to set about the adoption of means to render the tappet valve engine more quiet, so the introduction of the worm drive has led to great improvements being made in the method and means of hardening bevel gears to prevent warping, the chief cause of noise. One system employed with crown wheels is to copper-plate all except the teeth. The coated part is then not affected by the cementation process, and the wheel after dipping and the teeth hardened can be more easily got true. The fixing of a substantial tail bearing at an extension of the pinion shaft is found in connection with the Maudslay chassis.

Parallel torque and tension rods are also fitted. The springs are three-quarter elliptical, very long and wide, with the frame upturned over the back axle.

(To be continued.)

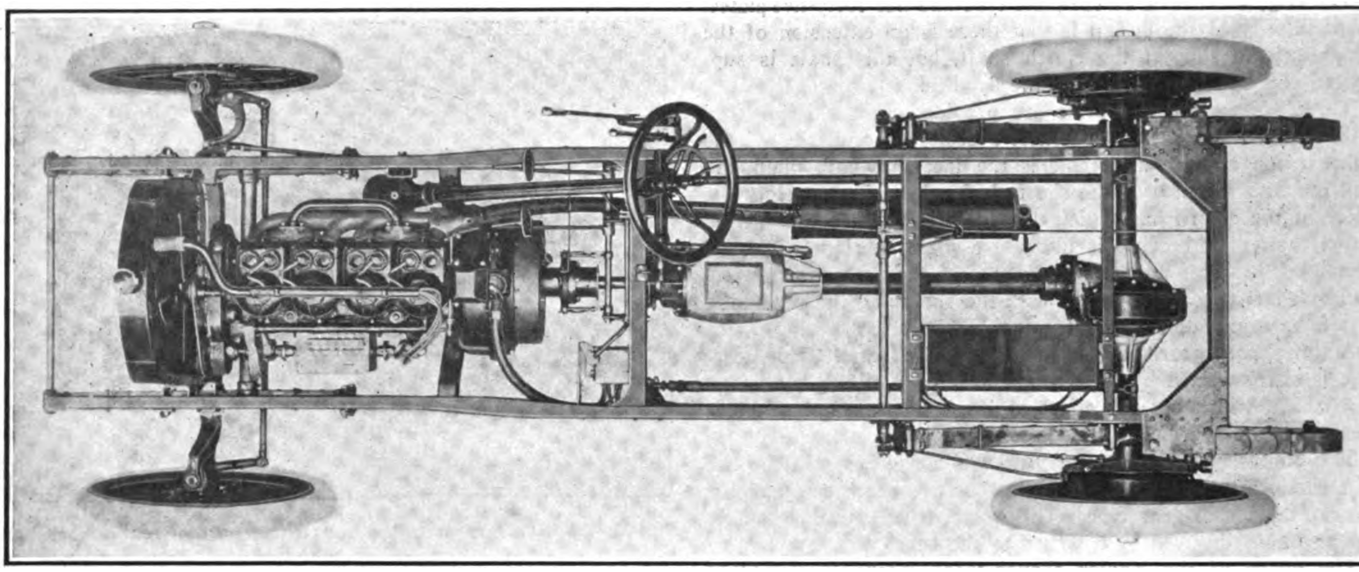

Fig. 1—Rambler Cross Country chassis, showing arrangement of torque, drive and suspension members

Rambler Drops All But the Cross Country Model

Principal Changes for 1913 Include Fitting of Electric Starting, Lighting and Ignition System; Change in Motor Dimensions and Fittings; Adoption of Cone Clutch and Adjustable Steering Column

FOR the season of 1913 there will be but one Rambler chassis on the market. This model, which is to be known as the Cross Country, will combine all the refinements which the Thos. B. Jeffery Company has made up to date. Among the prominent features are the combination electric starting and lighting system, the adoption of the Stromberg carbureter, increase in valve dimensions, longer connecting rods, better placing of wiring, adoption of the cone clutch, shortening of the hand stroke required to shift gears, simpler brake connections, and an adjustable steering column. The larger model Rambler which embodied a motor with a bore of 5 inches and a stroke of 5.5 inches has been discontinued. This was a heavier model.

Taking up the power plant which is designated by the makers as a gasoline-electric, it may be said that the gasoline engine has four cylinders of the L-head type with valves on the right side. The cylinders are cast separately and are 4.5 inches both bore and stroke. Though the motor has three bearings the use of the self-starter has not necessitated the addition of another bearing between motor and flywheel. The offset crankshaft which has been a feature of Rambler construction for many years is continued. It is shown in Fig. 3 together with the principal dimensions, but the connecting rods have been lengthened slightly to give less wear between pistons and cylinders.

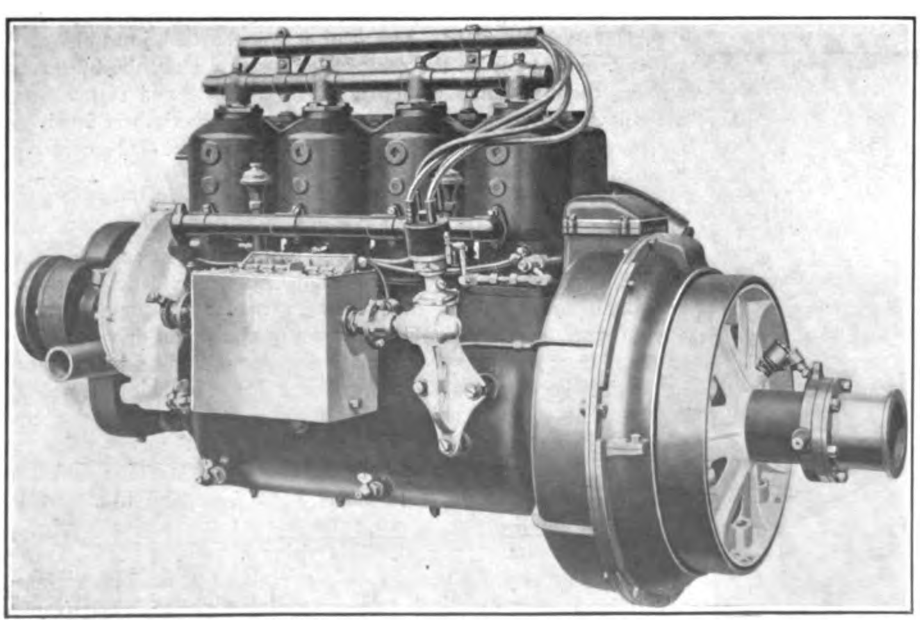

Fig. 2—Mounting of new mechanical oiler, showing longitudinal shaft drive and cone clutch

Both intake and exhaust valve have been increased to 2.125 inches in diameter and are interchangeable. The only other alteration in the motor is in the use of a Detroit mechanical oiler of 2 gallons capacity, located on the motor base at the left of the cylinder, Fig. 2. The oiler is a seven-feed type with four oil tubes leading to the cylinders and the remaining three to the crankshaft bearings. A splash is contained within the crankcase. The supply of oil is contained directly in the box that also houses the plunger pumps which send the oil through the leads to the different bearings and to the cylinders. This gives a combination of force-feed and splash although the system is non-return and non-circulating. As will be seen from the illustration there is a longitudinal shaft which passes through the mechanical oiler box terminating at one end at the timing gears from which it is driven and at the other end at the timer which is actuated by the shaft. Within the oiler box are seven small plunger pumps each operated from the longitudinal shaft by a small crank. By an ingenious arrangement the length of the stroke of each of these pumps can be lengthened or shortened by means of a nut located on top of the mechanical oiler box. When the stroke is shortened the supply of oil given through the lead that that particular pump takes care of, is correspondingly decreased. In the bottom of the crankcase are located draincocks which may be opened to allow the surplus oil which will gather in the crankcase in time to drain off. The filler hole for the mechanical oiler is located in the top of the box in the usual manner. Besides this there are two breather pipes communicating with the crankcase through which an additional supply of oil may be poured when it is desired to fill the crankcase, such as when the car is used for racing or if the supply in the crankcase has been removed while the old oil was cleaned out. The motor suspension is continued as a three-point support, a tubular cross piece, 2 inches in diameter, forming the front supporting members. The entire motor is mounted at a slight rearward slope to give a straight line drive to the rear axle.

Another change is in the use of a Stromberg carbureter with a hot-air jacket from the exhaust manifold on the footboard. Immediately in front of the steering post is a push button by which the air intake may be closed to give a richer mixture on starting. The new type of radiator, Fig. 8, which appeared for the first time in the 1912 cars is continued in the 1913 Cross Country. A belt-driven fan immediately behind the radiator is driven from the shaft upon which drives the pump and assists the latter in maintaining the cylinder cooling. Ignition wiring has been changed from position at the right side of the cylinder to a point immediately above the water manifold, where it is incased in a waterproof tube, as is shown in one of the motor illustrations.

Immediately behind the motor-generator-flywheel, which is hereinafter described, and partially within its housing is the clutch. The latter embodies a decided alteration from previous Rambler design in that for next year it is of the cone type instead of the internal expanding type which has been heretofore one of the features of this product. The new clutch is shown in Fig. 4 and is a direct acting cone in which gradual engagement is obtained by springs under the leather facing.

Located amidships on the chassis frame is the three-speed selective gearset, which embodies a slight change in design for 1913. The arrangement of the gears and control connections have been altered slightly, in order to decrease the movement of the hand required in changing speeds; heretofore it has necessitated a movement of the top of the gearset lever of nearly 1 foot, whereas, in the new arrangement the total movement is but 6 inches. There has been no change in the propeller shaft or rear axle, the latter being rigidly connected to the gearset by means of a torsion tube surrounding the propeller shaft. On each side of the propeller shaft tube are the torsion rods which, as for the past year, are in V form, the spreading arms attaching to vertical arms on the rear axle housing as shown in the chassis view, Fig. 1.

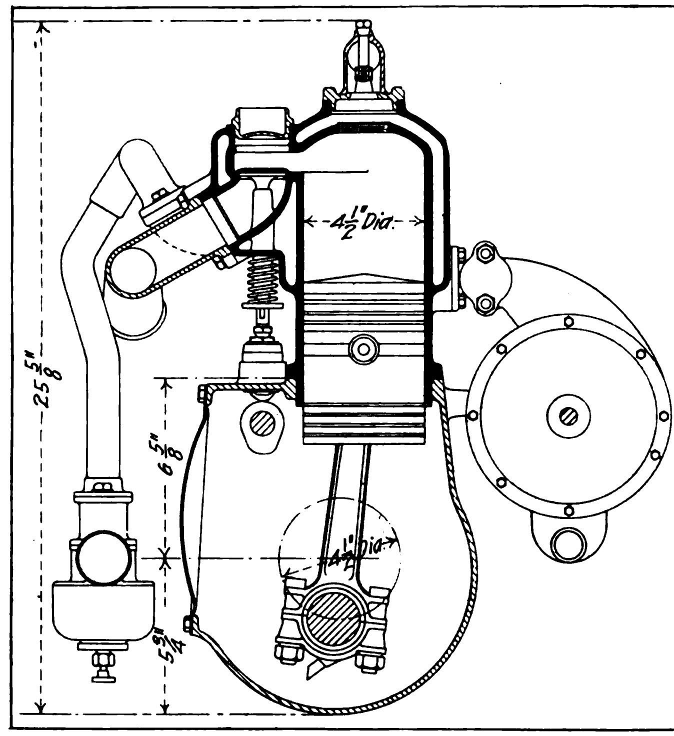

Fig. 3—Rambler 1913 cars will have longer connecting-rods and larger valves

The rear axle is of the floating type with roller bearings, drive axle shafts and gears forged integral and the wheels secured to the square taper axle end. The front axle is a drop-forged I-beam with an adjustable taper roller bearing.

The brakes are internal expanding and external contracting on the rear wheel drums, which are 14 inches in diameter and 2 1-2 inches in width. There has been a slight alteration in the brake connection which makes for simplicity in the new models. The

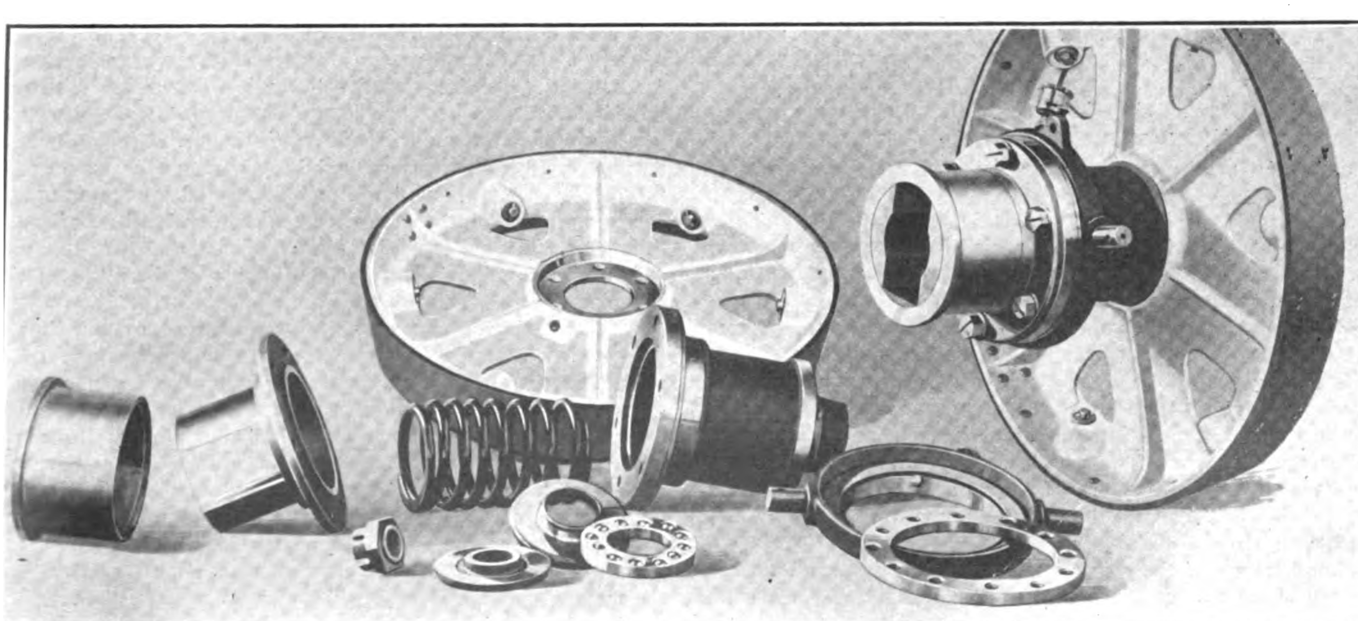

Fig. 4—Disassembled view of the cone clutch. New on the Rambler car for the 1913 season

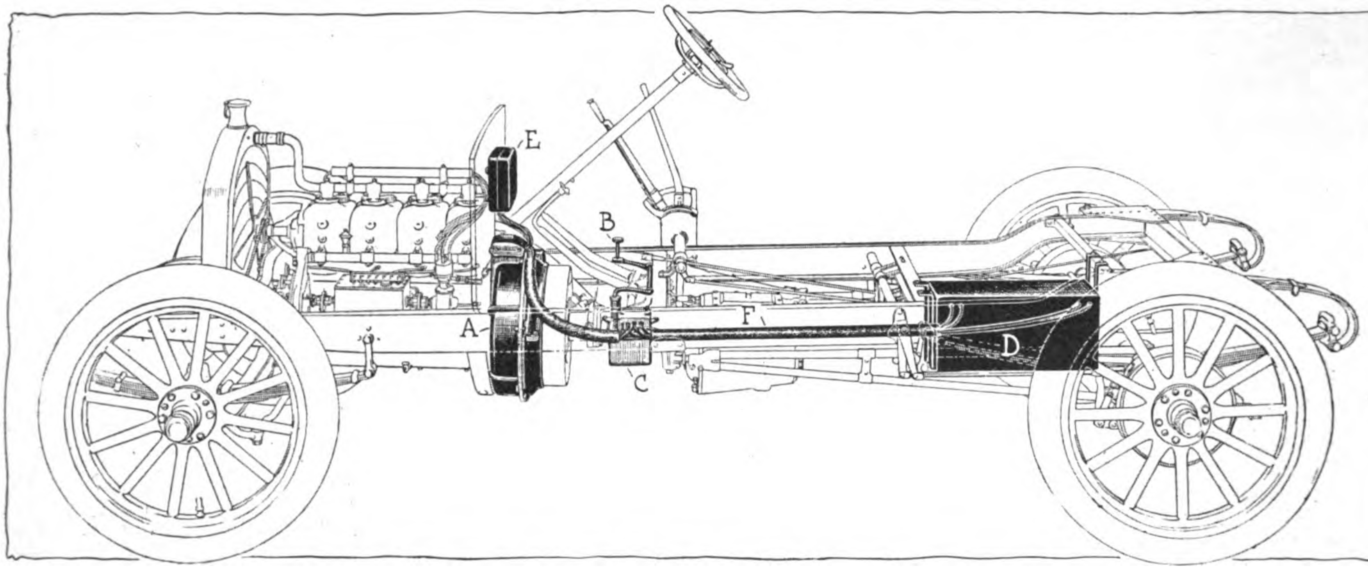

Fig. 5—Starter mounting. A, motor-generator; B, control; C, switch; D, accumulator; E, regulator, F, conduit

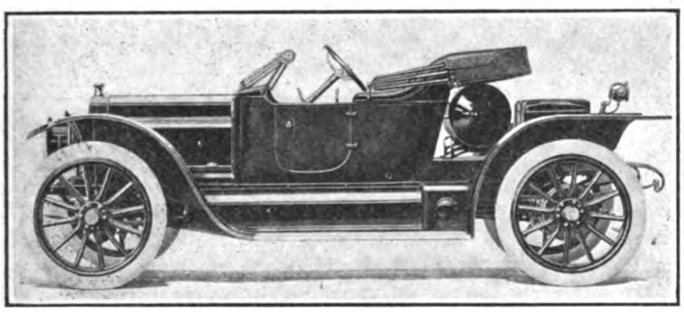

Fig. 6—Rambler roadster with rumble seat fitted aft of tank

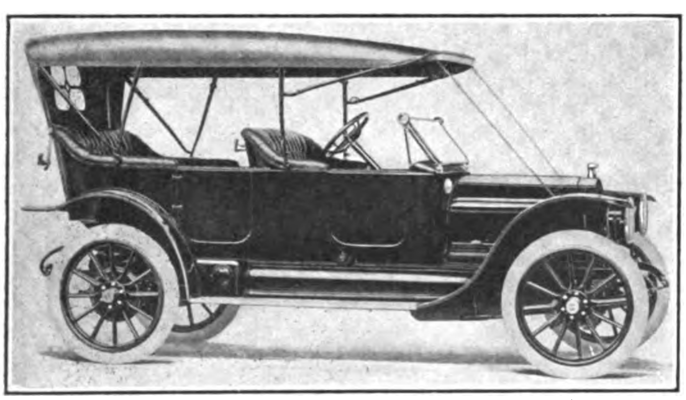

Fig. 7—Five-passenger touring car, Cross Country model, with full equipment

countershafts for the two brakes which formerly were separated, are now combined in one; one being located within the other; the outer one being in the form of a tube.

The frame construction is the same as that of the present model, being a tapering straight-line channel to just forward of the rear axle where there is a kick-up to clear the latter. Wide gusset plates are provided at the corners to prevent distortion. Springs are continued as semi-elliptic in front and three-quarter elliptic in the rear. The wheelbase is continued at 120 inches and the tires on all but one of the models—the Gotham, are 36 by 4 inches in size; with the latter body the tires are 37 by 4 1-2 inches in size.

Another one of the recent improvements which has been continued in the new model, is in the adjustable steering pillar. The steering column is hinged to the frame and the column rises through a slot in the floor. A metal plate through which this column passes covers this slot. The under side of the slot is serrated and these serrations mesh with others on the floorboards. Clamping bolts hold the plate in any desired position and by loosening the bolts the plate may be moved forward or aft, giving the steering column any desired tilt.

The starting, lighting and ignition system which is unique on account of its unit construction with the motor and because it is the first starter that has been fitted to the Rambler cars, may be briefly described.

The chief factor of this system is the motor generator. This system comprises: 1, a dynamo, which performs the functions of both motor and generator and replaces the flywheel of the gasoline engine, 2, a storage battery, 3, a switch operated by a foot pedal, and 4, a regulator, which is located upon the dash. The phantom view of the chassis shows these four elements as they are installed in the car. The chief portion of this system is, of course, the combination flywheel, electric motor and generator. As shown in one of the illustrations, the flywheel housing also has the function of the field frame, the eight field coils being wound on the cores which are bolted to the housing. Within this frame rotates the armature of the dynamo, taking the place of the usual flywheel and being attached to the crankshaft of the engine in the same way as the flywheel is attached. The crankshaft also carries the commutator, the brushes of which are carried on a ring just behind the armature and is held in place by bolts that pass through it for attachment of the rear portion of the housing. The fact that the flywheel is done away with permits its weight to be taken up in that of the dynamo so that the different parts can be made of ample size without increasing the weight of the system unduly. Consequently, all parts of the motor generator are large and substantial, the commutator, for instance, is 10 inches across and the carbon brushes, of which there are eight, are .75-inch square. It is stated that the total weight of the unit is slightly less than that of the flywheel that it replaces.

When running as a generator, the motor generator charges the storage battery at a 30-ampere rate and a pressure of 24 volts the controlling relay connecting battery and generator at speeds of from 8 to 10 miles per hour. To start, a foot button is pressed permitting current from the battery to run the motor generator as a motor at a voltage of 24 volts. The armature is rotated at 200 revolutions per minute and as the crankshaft of the gasoline engine is an integral part of the armature shaft, the engine is turning over at the same speed. Should the weather be cold and carburetion pure, the heat created by the friction of the moving parts, it is said, will warm them sufficiently to give the initial explosions. When the engine is running on its own power, the electric motor automatically changes into an electric generator to charge the battery. Lights are supplied with current from the battery at pressure of 6 volts and ignition at 12 volts, the electric system displacing a magneto as a source of ignition current. The generator charges the battery at the rate of 30 amperes, while the current required for ignition, and lighting, is together 9 amperes, while it is stated that the amount usually required for starting is replenished within 2 minutes after the motor has attained a speed of from 10 to 15 miles per hour. The controller is designed to automatically disconnect the storage battery and generator when the speed of the motor drops below that sufficient to charge, so that there is no opportunity for the battery to discharge through the motor except for starting purposes. The starting button operates an oil switch on the chassis frame side member and the storage battery is hung between two cross members of the frame below the tonneau.

Five different bodies are fitted to the Cross Country chassis. These include a four-passenger touring, a five-passenger touring, a two-passenger roadster, a Sedan body with inside drives and seating four passengers and a Gotham or limousine body with inside drive, seating seven. The bodies are trimmed in nickel with body fenders and fillers of black enamel. The upholstering has been increased from 8 to 10 inches depth and a bumper has been fitted on the forward ends of the front springs. The electric lighting equipment includes 9 1-4 inches headlamps with port dashlamps flush with the dash line. The rear lamp is mounted on the fender and has a twist switch so that it will comply with local city ordinances.

Aside from standard equipment, the features of the Cross Country roadster, in the matter of accessories, is that of the trunk rack with two suit cases; the two closed bodies are trimmed in gray bedford cord with electric piller lights between driver's seat and rear compartment, in the case of the Gotham body, and electric dome light in case of the Sedan.

Harking Back a Decade

FROM *The Automobile and Motor Review*, November 15, 1902: Emil Grossman has sold his interest in *The Automobile and Motor Review* to H. M. Swetland. Mr. Grossman will retire from the company immediately.

Commander Wells, of the London Fire Brigade, has introduced an automobile fire engine into the metropolitan service. His experiment consists of converting a horse-drawn steamer into an automobile, the work being done in the shops of the department. The propelling engine is a two-cylinder steam motor.

M. H. Kilmer, of Ocean Grove, N. J., recently spent 27 days in touring the Catskills. It rained 14 days of the time, but Mr. Kilmer, who was on vacation, declares that he never enjoyed a tour so much as the one he made. He kept an approximate record of his mileage, and says that he averaged nearly 100 miles a day. His total repair bills were $3.30.

A straightaway speedway for the exclusive use of automobiles is being planned across the Jersey Meadows, connecting the west bank of the Hudson with the excellent highways in the northern part of New Jersey. The plan involves the laying of concave steel rails in a slightly crowned road surface. It is planned to sow grass seed between the rails to solve the dust problem. W. J. Stewart, of the Automobile Club of New Jersey, is the proposer of the plan.

Factory Miscellany

Giant crane which runs the length of the frame arm of the factory. The crane spans that section of the factory and has a track 800 feet in length

QUANTITY production means the necessity of transferring tons of material through a considerable distance. Reduced to ton-miles the amount of work done in the Ford factory would astonish the average individual. The above illustration shows one of the cranes that render possible the speed at which the Ford car is turned out. Every 58 minutes a car is assembled. A constant supply of heavy parts must be delivered to the assembling room so that there shall be no delay. These cranes do the work. As may be seen from a study of the illustration, the crane extends directly across the frame arm of the factory. The length of the track is 800 feet and the crane can travel this distance at a speed of about 15 miles an hour. Throughout the factory the Ford company has eliminated the truckman and nowhere are to be seen men who struggle behind an overloaded truck, a common sight in many factories. One of the most useful cranes is a big gantry crane not shown in the illustration that labors in connection with the foundry. This crane on stilts walks along over freight cars, picking out their loads of pig iron or scrap or shoveling out their loads of sand. It has a 6-ton clam shell shovel for raising sand and gravel. It hoists pig iron and scrap with a gigantic magnet. This is dropped into the metal and current thrown on. It is then raised, covered with bars of pig and pieces of scrap. When this load is over the place where it is desired to deposit it, the magnet is lowered and the electric current switched off. The magnet is a magnet no longer and the metal drops.

NEW SYRACUSE FACTORY—The New Process Raw Hide Company, Syracuse, N. Y., has erected additions which the company claims makes its complete plant the largest single plant in the world devoted exclusively to gear-making and gear-cutting. The latest additions are a four-story and basement wing extending 65 feet by 180 feet at right angles to the old building and a heating plant in the rear 60 feet by 50 feet housing three 125 horsepower boilers. The new buildings are fireproof throughout, having steel framework, reinforced concrete floors, concrete roofs, brick curtain walls and steel window sash. New equipment to the extent of $100,000 has been installed. The accompanying photograph shows the factory.

Syracuse Company Moves—The Precision Die-Casting Company, Syracuse, N. Y., has moved into its new offices and factory.

Cadillac Factory News—The Cadillac Motor Car Company, Detroit, Mich., is now turning out sixty cars a day, having a force of 5,500 men.

Goodrich Entertains Clevelanders—The B. F. Goodrich company, Akron, O., recently entertained at its factory 410 members of the Cleveland Chamber of Commerce.

Cutting's Kansas City Factory—The Cutting Motor Car Company, Jackson, Mich., has completed arrangements for a branch factory at Kansas City, Mo., to cover western territory.

Gregg Starts Body Factory—W. S. Gregg has started in a business for himself, in a new modern two-story brick building, Los Angeles, Cal., erected for the purpose, where he will manufacture automobile bodies, windshields and rims.

Canadian Factory Progress—In 10 years automobile plants in Canada have increased 4,559 in number, $798,829,009 in value of capital, 175,108 in number of persons employed, $127,274,301 in earnings of salaries and wages and $683,722,-157 in value of products.

To Build Beaver Six—The Beaver Six is the name of a new automobile to be manufactured in Portland, Ore. A group of Portland business men have filed incorporation papers for the $300,000 Beaver State Motor Company. The first automobile has been manufactured and in a short time announcement will be made of the site of a $30,000 plant. P. A. Coombs and J. A. Friddle are the designers of the car, which will be on two models, roadster and touring car of 45 horsepower.

Growth of Canadian Industry—The growth of Canadian nanufacture is well illustrated by the progress being made by the Brockville, Ont., Atlas Automobile Company. This company will build additions in the near future that will riple the present premises.

To Manufacture Trucks—Theodore D. Gere and Frank B. Tracy, of Owego, N. Y., have formed a partnership to manuacture a commercial motor truck and negotiations are in progress for leasing the Robert Nichols building in Owego or the manufacturing plant.

Orders New Equipment—The Lewis Electric Welding Company, has placed an order for new equipment which will ncrease both its scope and output. The company has maerially increased its capitalization and will soon enter upon he manufacture of an increased line of automobile parts.

Toledo Company Adds—The Electric Auto-Lite Company, Toledo, O., will build an addition to its plant in that city, roviding for 40,000 square feet of floor-space. The work is lready under way and the company expects to be installed n the new building before January 1.

Moon Installs Equipment—The Moon Motor Car Comany, St. Louis, Mo., plans to make further improvements to s plant and to install a large amount of new equipment. During the past season, additions have been made to the lant which more than doubled its capacity.

Accessory Plant Planned—The Ernest Lee Machine Comany, Cleveland, O., has had plans prepared for the construcon of a factory for the manufacture of automobile accesories. The plans call for a one-story brick structure, 100 et by 320 feet, at an estimated cost of $15,000.

To Build Truck in Boston—The Frank Rilion Company, ell known in the electrical field in New England with headuarters in Boston, has decided to build motor trucks of om 1 to 6 tons capacity designed by Victor J. Houdon. The ehicles will be built in the present workshops in South oston.

Visit Cleveland Plants—The engineers of western Pennlvania, with headquarters at Pittsburgh, have arranged with e Cleveland Engineering Society for a joint inspection trip rough several Cleveland manufacturing plants, including e Winton Motor Car Company and the White Motor Car ompany.

Marathon Builds—The Marathon Tire & Rubber Comny, Cuyahoga Falls, O., is constructing a 65 feet by 300 et building in which new machinery is to be installed as on as possible. The company was recently organized for e purpose of manufacturing inner tubes and a general line rubber goods.

Westinghouse Plant Increased—The Westinghouse Elecic and Manufacturing Company, Pittsburgh, Pa., has rented e first floor of a large building, and is installing machinery. The new plant will be used for the manufacture of automole accessories and will employ 200 men and an equal numr of women.

Philadelphia's Police Regulation—Automobile equipped th two pairs of lamps or lights must use only the less brilnt pair on streets with railway tracks and on Broad street d Diamond street and Twenty-first street within the disct bounded by the Delaware and Schuylkill Rivers and ie avenue and South street.

Ford's New Plant—The Ford Motor Company, Detroit, ich., has opened up a new assembling and service departent at Sixteenth street and Washington avenue, that city.

Shows, Conventions, Etc.

Dec. 7-22..........Paris, France, Paris Automobile Show, Grand Palais.
Jan. 11-22.........Brussels, Belgium, Annual Belgian Automobile Show, Centenary Palace.
March ....France, Sealed Bonnet 3000-Mile Run.
April ....Barcelona, Spain, International Exhibition.

The cars are sent from the factory to this department in a knocked-down condition, where they are assembled and sent to the various agencies. Besides the assembling room there are the general offices and a large stock room, where a complete stock of parts is carried.

View of the complete new plant of the New Process Raw Hide Company, Syracuse, N. Y., including the recent additions

News of the Week Condensed

Cartercar pay car used by the Detroit, Mich., department of public works. It saves time and precludes losing the pay rolls

PAID from Cartercar—By adopting a system of paying the Detroit, Mich., employees in the department of public works from the new city pay car, the city paymaster is able to save much time, and also eliminate any risk of losing the payrolls. The accompanying illustration shows part of a line of sixty men being paid off, the entire operation requiring only 10 minutes from the time the car enters the yards. The new car is the product of the Cartercar Company, Pontiac, Mich.

Delmore Opens Garage—E. J. Delmore, formerly with the Windsor, Ont., Hupmobile plant, has opened a garage in Reese, Mich.

Against Bulb Horn—Los Angeles, Cal., has just enacted an ordinance directed against the use of the bulb horn an as automobile warning signal.

Spare Succeeds Skilton—R. Y. Spare has succeeded R. J. Skilton as manager of the retail sales force of the Oldsmobile Company, Philadelphia, Pa.

Sullivan Alco Manager—The American Locomotive Company, Providence, R. I., has appointed G. L. Sullivan manager of the Chicago, Ill., branch.

Welch Manager Michigan—The Michigan Motor Car Company, Kalamazoo, Mich., has appointed E. A. Welch eastern sales manager, with headquarters in that city.

Fletcher Truck Manager—H. R. Fletcher has been appointed to take charge of the sales of the Flanders truck for the E. V. Stratton Company, Albany, N. Y.

Franklin Sales Conference—The annual conference of the district sales managers of the Franklin Automobile Company, Syracuse, N. Y., will be held at the factory on November 21 and 22.

Buick Savannah Factory Branch—A factory branch of the Buick Motor Company, Flint, Mich., is to be established in Savannah, Ga. J. E. Finney will remain at the head of the concern.

Knight Tire in Atlanta—The Knight Tire & Rubber Company, Canton, O., manufacturer of the Knight tires, has opened a branch office in Atlanta, Ga., under the management of H. C. Ross.

Motz Opens Branch—The Motz Tire & Rubber Company, Akron, O., has installed a direct Boston, Mass., branch. M. A. Frank is in charge of this new branch, which is located at 4 Dundee street.

Durston Resigns—R. H. Durston has severed his connection with the Syracuse, N. Y., office of the American Cole Company and will in the future devote his time to an automobile business with J. Bowman.

Want Large Membership—An effort is being made by the Alabama Good Roads Association to swell its membership to 10,000. Speakers of the association will visit each county in the state during the winter to preach the doctrine of good roads.

Automobile in National Park—In order to take care of the tourist travel in Glacier National Park next year, A. Brewster, of Belton, Mont., has just purchased six Chalmers cars, which will make regular trips from Glacier Park station to St. Mary's Lake.

Richmond Show Association Formed—The Richmond Automobile Dealers' Show Association, Richmond, Va., organized for the purpose of conducting automobile shows and racing events in that city, has been chartered by the state Corporation Commission.

Wetmore at Y. M. C. A.—The opening of the tenth year of the West Side Y. M. C. A. automobile school occurs next Thursday evening, November 21, when J. C. Wetmore will speak on "The Chauffeur, a Potent Factor in the Advancement of the Automobile."

Drown with Steel Concern—J. W. Drown, formerly advertising manager of the Standard Roller Bearing Company, Philadelphia, Pa., has resigned and accepted a position as sales manager of the Pressed Steel Manufacturing Company, 504 Land Title Building, that city.

To Open Newark Salesroom—A new showroom in Newark, N. J., is soon to be opened. It is located on Halsey street and occupies nearly 20,000 square feet of floor-space. The enterprise is headed by Messrs. Dalley and Van Vleck, who will handle the Touraine Six.

Cumberland's $40,000 Garage—The Cumberland Motor Company, Nashville, Tenn., is erecting a garage and sales room at Fifteenth street and Broadway, the total cost amounting to $40,000. The salesroom which fronts on Broadway will extend 100 feet across and 40 feet deep.

A Modern Garage—The modern garage is the title which Philo C. Fuller, of Grand Rapids, will confer upon the $85,000 automobile palace which he is now erecting. The structure will be of Spanish architectural type, with a three-story angle and one-story wings. It will be 140 feet by 100 feet in size.

New Agencies Established During the Week

Motor Train Service—The Chicago, Terre Haute and outheastern Railway Company has established motor train :rvice between Terre Haute and Dana, Ind.

Annapolis Boulevard Completed—The Annapolis boulevard :tween Boone and Revelle has been completed so that now ere is a continuous stretch of boulevard from Brooklyn to nnapolis.

Chase Manager The Falk Company—C. F. Chase has been ›pointed sales manager of the gas engine department of The ılk Company of Milwaukee, Wis., which also manufactures kerosene gas engine.

Cool Pathfinder Manager—H. G. Salisbury, recently ap›inted general manager of the Pathfinder Motor Car Comny of California, has appointed Barry Cool manager of the .n Francisco branch.

Ijams in Chicago—R. L. Ijams, assistant to C. A. Gilbert, :stern district manager of the United States Tire Comny, has been transferred to the central district under J. C. eston with headquarters in Chicago, Ill.

Kingsford Leaves Peerless—Mr. Russell T. Kingsford has signed his connection with the Peerless Motor Car Comny, Detroit, Mich., to accept the position of chief engineer th the Rushmore Dynamo Works, Plainfield, N. J.

Perkins with Rushmore—Mr. J. Perkins, for several years perintendent of the Saurer motor truck factory of the In'national Motor Company at Plainfield, N. J., has resigned ; position there, to become superintendent of the Rush›re Dynamo Works, Plainfield.

Small Resigns—Allen H. Small, assistant manager of the lwaukee, Wis., branch of the Buick Motor Company for me time, has resigned to accept the position of district ınager for the Oakland-Wisconsin Motor Company, state ent for the Oakland, Empire and Detroiter.

Reavell Manager Diamond—O. C. Reavell has been transred to the management of the Indianapolis branch of the amond Tire and Rubber Company, Akron, O. He succeeds W. Fauvre, who has been advanced to manager of the npany's Chicago, Ill., sales and distributing branch.

Wants Motor Trucks—Commissioner Edwards of Salem, ıss., who has charge of the street cleaning department, ns to request the board of aldermen to make an approation for 25 motor trucks to be used as garbage wagons to e the place of the horse-drawn vehicles now in use.

Highway Commission Inspection—The members of the ıssachusetts Highway Commission started recently on ir annual inspection of the roads and bridges of the Bay te and before they finish they will have visited 320 towns l 33 cities. They are making the run in a Locomobile.

Stewart Traveling Representative—Roy D. Stewart, forrly mechanical manager of the Milwaukee, Wis., branch the Thos. B. Jeffery Company, and more recently manr of the Walsh & Schulz garage, has resigned to become sconsin traveling representative of the Vacuum Oil Comıy.

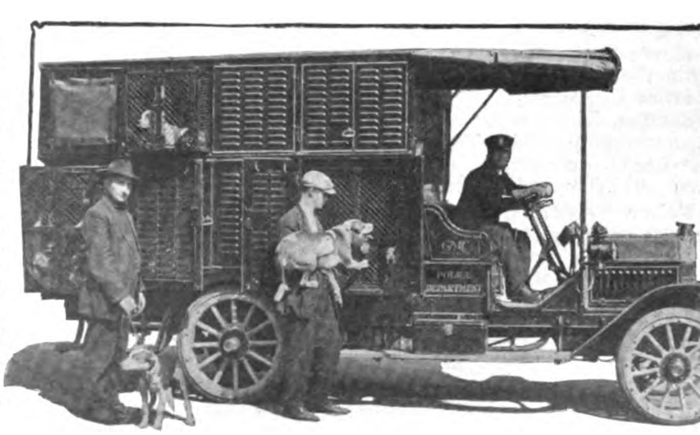
Walker Makes a Change—Warren T. Walker, formerly h the Locomobile and Matheson branches in Boston, Mass., has been appointed manager of the Boston branch of the Kelly-Springfield tire company, succeeding Manager Beach, who has been sent to take charge of the San Francisco, Cal., branch.

Highway Construction Completed—An interesting piece of highway construction known as the Rincon sea-level cut-off has just been completed. The road saves 9 miles between Ventura and Santa Barbara, Cal., and eliminates the dangerous Casitas Pass, with its climb of 1,200 feet and its dangerous and narrow roads.

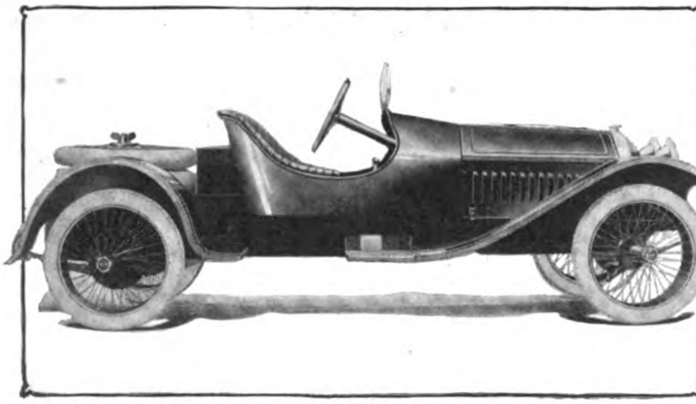
Cadillac Moves—The Jonas Automobile Company, representing the Cadillac, has moved into its new home, the Cadillac Building, Milwaukee, Wis. The former quarters at 417-421 Wells street are now occupied by the Wolleager Auto Sales Company, successor to the Milwaukee branch of the Studebaker Corporation.

United Tire's Agencies—The United States Tire Company has recently opened new sub-branches in Newark, N. J.; Birmingham, Ala.; Rochester, N. Y.; Washington, D. C., and Milwaukee, Wis. In the near future sub-branches also will be opened in Providence, R. I.; Worcester, Mass.; Baltimore, Md.; Syracuse, N. Y., and in Columbus and Toledo, O.

Cadillac Breaks Record—The Los Angeles-San Francisco, Cal., record over what is known as the valley or inland route, one of the road classics of California, was broken recently by a 1913 Cadillac, driven by Charles Soules, the former racing driver. The distance is close to 500 miles, and the Cadillac negotiated the run in 17 hours and 5 minutes. This time breaks the old record by 40 minutes.



The latest addition to the Detroit fleet of municipal trucks is a G.M.C. dog catcher's wagon. The vehicle is operated under the direction of the Detroit police department and is impounding on the average of ninety muzzleless canines per day. The new wagon is designed to carry the dogs in the most humane manner possible. Fourteen cages of various sizes are provided and whenever it is necessary, a vicious dog may be kept apart from the others in a separate compartment



One of the new Oakland models, the six-cylinder, 60-horsepower two-passenger roadster

Wilder in New Rooms—The Wilder Motor Car Company is now occupying its new salesroom in Louisville, Ky.

Robartes Locomobile Manager—F. W. Robartes has been appointed manager of the Washington, D. C., branch of the Locomobile Company, succeeding James J. Flynn.

Savannah Run on Thanksgiving—Preliminary arrangements for an automobile run on Thansgiving Day are being perfected by the Savannah Automobile Club, Savannah, Ga.

Goodloe Atlanta Manager—T. B. Goodloe, who has been in charge of the Richmond, Va., sub-branch of the United States Tire Company, has been appointed manager of the Atlanta, Ga., branch of the same organization. Mr. Goodloe is succeeded in Richmond by J. G. Given.

Prest-O-Lite in Portland—The Prest-O-Lite Company, Indianapolis, Ind., recently opened a factory branch in Portland, Ore., and word has now just been given by H. H. Van Horn, who will have management of the branch, that the Searchlight Gas Company of Chicago, Ill., will establish its northwest branch in Portland.

Garage Cost $30,000—John B. Hauf, of Albany, N. Y., is having constructed in that city a garage and storehouse. The dimensions of the new building are 110 feet by 44 feet; its cost is to be about $30,000. The new building will be absolutely fireproof, consisting of four stories, the first two being for the garage.

Sager Selected—The Cadillac Motor Car Company, and the Packard Motor Car Company, both of Detroit, Mich., have selected the Sager Diamond Bumper, made exclusively by the J. H. Sager Company, Rochester, N. Y., who have been granted letters patent covering both mechanical and ornamental design.

Clearing House Success—When the automobile clearing house was first formed in Seattle, Wash., it was with the idea of keeping it going not more than a month, but owing to the wonderful success of the venture it has been made a permanent institution on automobile row and it bids fair to be one of the largest automobile concerns on the Pacific Coast in a year's time.

Kurtz Retires—E. W. Kurtz has announced his retirement from the position of director of advertising for the General Motors Company, Detroit, Mich., the work and purpose of the advertising department of the General Motors having been accomplished. This department at the general offices has been discontinued, each individual plant now having its own publicity and advertising department.

Frisco Selling Organization—A new kind of automobile selling organization is being tried out in California and is being watched with a great deal of interest by San Francisco dealers. The organization is known as the Mutual Motor Agencies of Northern California, and is composed of small automobile concerns organized for the special purpose of pushing a popular-priced automobile on the market.

Lamb-Daniel Company Formed—H. A. Daniel, formerly purchasing agent of the Carter Car Company, Pontiac, Mich., and J. J. Lamb, a local advertising man, are the principal figures in a newly formed concern in that city to be known as Lamb-Daniel & Company, with headquarters in the Union Trust Building. The new firm will act as manufacturers' representative for several Detroit automobile parts manufacturers.

Convicts Construct Automobile—Convicts at Sing Sing prison, New York State, have completed the construction of an automobile with exception of the engine, which was purchased from a motor dealer. Commissioner Edwards of the street cleaning department of New York City will inspect the machine and if satisfactory it will be purchased and installed in the street cleaning department of the metropolis at a cost of $5,000.

San Joseites Organize—At the beginning of October a number of the automobile enthusiasts of San Jose, Cal., organized a motor club in that city. Within 2 weeks they secured a membership of 275, raised $45,000 actual cash, have purchased 90 acres of Toothill land near Alum Roçk, and have let a contract for an extensive club house and the laying out of extensive grounds. The officers are: W. S. Clayton, president; John R. Chance, secretary; Albert Bettins, treasurer.

Minneapolis Busy Building—Three automobile buildings are being constructed in Minneapolis, Minn., for Andersch Brothers, Abbott-Detroit, to cost $35,000; for The Colby Motor company, to cost $10,000 and for the Bowman & Libby, Inc., Overland, and the Goodyear Tire & Rubber company, to cost $100,000. The Ford Motor company will erect a $200,000 building and the Avery company, Peoria, Ill., has bought a site for an implement and automobile building.

Dayton Tire Suit—The Victor Inner Tire & Rubber Company, Dayton, O., is the defendant in a recently filed suit in the United States District Court brought by Cecil Adamson, East Palestine, O., who alleges that the concern has infringed on a patent on improvement in tire vulcanizing repair apparatus. He asks $5,000 damages, an accounting and an injunction restraining the defendants from further infringement on his patents. J. Everett Inman and George Inman are named in the suit.

Washington Company's Troubles.—An involuntary petition in bankruptcy has been filed against the F. K. B. Company, Washington, D. C., automobile supplies, at 1110-1112 Fourteenth street, N. W., by the Continental Rubber Company, R. E. Dietz Company and the Commercial National Bank of that city, whose claims aggregate $12,000. The assets are said to be about $7,000. The bankruptcy court awarded adjudication, referred the case to a referee in bankruptcy and appointed Wilton J. Lambert and L. P. Loving receivers under a bond of $10,000.

Wisconsin Expends $950,000—A review of the highway situation in Wisconsin at this time presents a most satisfactory state of affairs. During the past year approximately $950,000 has been expended in permanent highway improvement and the estimates for next year, based on the demands of the counties for state aid, are in excess of $1,750,000. The report of A. R. Hirst, chief engineer of the Wisconsin State Highway Commission, shows that the counties are asking $811,150 from the state for permanent work in 1913, as compared with $453,417 demanded for 1912 work. Engineer Hirst's report shows that about 35 miles of concrete road were constructed during the closing season. The average cost is 90 cents per square yard.

Automobile Incorporations

AUTOMOBILES AND PARTS

AUBURN, IND.—De Sota Motor Car Company; capital, $20,000; to manufacture automobiles. Incorporators: L. M. Field, Hayes Fry, Glenn Fry, V. Van Sickle, H. J. Clark.

CHICAGO, ILL.—Keeton Motor Company; capital, $60,000; to manufacture automobiles and accessories. Incorporators: L. C. Roberts, K. R. Roberts, W. C. Spenny.

CLEVELAND, O.—Auto Mart Company; capital, $10,000; to deal in and rent automobiles. Incorporators: Edward C. Plietz, W. L. Radcliffe, William H. Hasselman, William R. Wallace, Louis C. Heimberger.

CLEVELAND, O.—Hall-Miller Auto Company; capital, $5,000; to deal in automobiles of all kinds. Incorporators: Joseph A. Freund, Jr., A. M. Freund, L. Greenfield, Charles Kovanda, J. A. Freund.

CLEVELAND, O.—Motor Mechanism Company; capital, $25,000; to manufacture automobiles and parts. Incorporators: Edward Younger, Florence Castle, Herbert O. Evans, H. E. Gray, S. E. Sackerman.

CLEVELAND, O.—Northern Ohio Motor Company; capital, $25,000; to deal in automobiles. Incorporators: Herbert W. Bell, E. L. Benning, F. C. Anselm, E. P. Elrich.

DANBURY, CONN.—Fillow Auto Company; capital, $30,000; to manufacture automobiles. Incorporators: A. Homer Fillow, Joseph W. Juengst, B. M. Fillow.

INDIANAPOLIS, IND.—Hunter-Hammond Auto Company; capital, $12,000; to manufacture automobiles and accessories.

NEW YORK CITY, N. Y.—Foreign & Domestic Automobile Repair Company; capital $10,000; to manufacture automobiles. Incorporators: L. O. Rothschild, Otto A. Deffea, Max Kaplan.

NEWARK, N. J.—Van Deman & Wainwright; capital, $50,000; to conduct a general automobile business. Incorporators: A. J. Thurstans, W. A. Waters, J. Rose.

TORONTO, CAN.—Standard Garage, Ltd.; capital, $40,000; to manufacture automobiles. Incorporators: Samuel W. Marchment, Harold W. Marchment, Douglas L. Berwick.

Ayers in Charge—J. C. Ayers has taken the managership of ıe General Motors Truck Company's Detroit branch.

Clement Production Manager—C. M. Clement has become roduction manager of the Metal Products Company, De-·oit, Mich.

Somerville Sales Manager—W. A. Somerville has taken the osition of sales manager of the Stromberg Motor Devices ompany, Chicago, Ill.

Addition to Ford Branch—Ground has been broken for the :w addition of the Ford Auto Company, Baltimore, Md., hich is to join the present building.

Losey Buick Manager—R. H. Losey, formerly of Indian-ıolis, Ind., has been named manager of the Atlanta, Ga., ·anch of the Buick Motor Company.

Flynn Resigns—James J. Flynn has resigned as manager of e Washington, D. C., branch of the Locomobile Company. is successor has not yet been appointed.

Ong Office Manager—The Sterling Auto Company, Detroit, ich., has engaged D. G. Ong, former paymaster of the anders Motor Company, as office manager.

Municipal Garage for Providence—The work of motorizing e municipal department of Providence, R. I., has progressed far that a municipal garage has been established.

Jenkins With Abbott—W. M. Jenkins, former sales man-er of the Simplex Motor Car Company has become Pacific ıast representative of the Abbott Motor Company.

Albany's Parade—Albany, N. Y., had an automobile parade :ently. Headed by a band on a Mack truck the column sembled at Central avenue and Northern boulevard.

Franklin Dealer Moves—The H. J. Mich Auto Company, nneapolis, Minn., Franklin dealer, has moved into a new esroom and service station at 1400 Hennepin avenue.

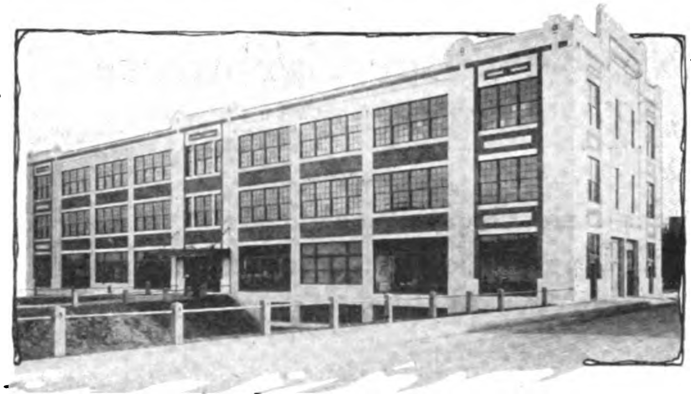
Secoir with Studebaker—Carl J. Secoir, purchasing agent the Havers Motor Car Company, Port Huron, Mich., has ned the forces of the Studebaker Corporation, Detroit, ch.

KisselKar Branch Moves—The Boston branch of the Kis-Kar Company moved recently from the Motor Mart into new building just completed for the branch on Common-alth avenue.

Wilcox Gives Dinner—The H. E. Wilcox Motor Car Com-ıy, Minneapolis, Minn., gave a dinner at the Kaiserhof ing Made in Minneapolis Week, for 125 drivers of Wilcox :ks in that city.

New Oakland Branch—The Oakland Motor Car Company opened a new branch at Houston, Texas, with A. J. Chal-ıir in charge. Mr. Challinoir was formerly connected with factory at Pontiac, Mich.

Buys Gasoline Cars—The Northern Central Railway has chased eight gasoline motor cars for use in its mainte-ce of way department on the Columbia and Frederick branch between Columbia, Pa., and Frederick, Md., a distance of 68 miles.



New sales and service building of the Thomas B. Jeffery Company in Boston, Mass.

Maus Joins U. S. Tire—John B. Maus has joined the United States Tire Company's selling forces in the capacity of special assistant to O. S. Tweedy, eastern district manager. Mr. Maus will have his headquarters in New York.

To Handle Great Western—The Great Western Auto Sales Company has been formed in Indianapolis, Ind., by C. E. Williams and J. E. Williams and will distribute the Great Western line of cars in Indianapolis and vicinity.

Nakes Chosen President—At the annual meeting of the Albany Automobile Dealers Association, Albany, N. Y., held in the office of the Dominant Motor Car Company, Chauncey D. Nakes, of Albany Garage, was chosen president.

New Home for White Company—The White Company has purchased more than an acre of land on Commonwealth avenue, Boston, Mass., next to the new KisselKar building, on which will be erected a salesroom and service department.

Baltimore Franklin Moves—The Baltimore branch of the Franklin Automobile Company, Baltimore, Md., has moved into new quarters at 1919 N. Charles street, and a thoroughly up-to-date service station has been established at the new address.

Motz Changes to Branch—The Motz Tire & Rubber Company has changed its line in Boston, Mass., formerly handled by the Standard Tire & Rubber Company as an agency proposition to a factory branch with M. A. Frank as manager and headquarters at 4 Dundee street.

Cobb Is Manager—A. M. Cobb, formerly manager of the Thomas branch, Chicago, Ill., has succeeded to the position of manager of the Velie branch left vacant by the retirement of Morton H. Luce, who goes to New York representing the Marion and American. George L. Sullivan, of New York, has been appointed manager of the local Alco branch in place of B. C. Day.

Baker Sales Show Increase—The sales increase in the pleasure car department of the Baker Motor Vehicle Company, Cleveland, O., for October, 1912, shows a net gain over October, 1911, of 123 per cent. This is 36½ per cent. higher than the total sales for April, 1911, which marked previously the greatest monthly volume of sales in the history of the Baker Company.

Haynes' New Alloy—Elwood Haynes of the Haynes Automobile Company, Kokomo, Ind., was the principal speaker at a meeting of the Indiana branch of the American Chemical Society held in Indianapolis one night recently. Mr. Haynes explained a new alloy which he recently discovered, and which he believes will revolutionize the manufacture of surgical instruments and hard metal tools.

Vehicle Club Election—The Electric Vehicle Club, of Boston, held its annual meeting at which plans for reorganization were discussed. The organization committee was instructed to prepare a constitution and by-laws for presentation at the next meeting. The following officers were elected: Day Baker, president; E. S. Mansfield, vice-president; H. S. Thompson, secretary; J. S. Codman, treasurer.

Rochester Club Elects—At the annual meeting and election of officers of the Rochester Automobile Dealers Association, Rochester, N. Y., Frank W. Peck was unanimously re-elected president, while C. E. Hartson was chosen again for vice-president. George J. Bauer was elected secretary. A. F. Crittenden, who has withdrawn from the automobile business, resigned from the treasurership and was succeeded by F. R. Luescher.

CHANGES OF NAME AND CAPITAL

RTON, O.—Heathman Soliday Motor Company; name changed to Frank eathman Motor Company.

New-Miller Carbureter Has Three Adjustments

Float-Feed Device Incorporates Many Novel Features—Interconnected Throttle and Air Valves

New and Ingenious Tools Used in Making Product Which Can Be Turned Out at Rate of 400 Per Day

A NEW style carbureter has been brought out by the New-Miller Manufacturing Company, which is worthy of attention because it involves several new and seemingly exceptionally desirable features. One of the greatest advantages of this carbureter would appear to lie in the fact that the gasoline level is co-incident with the fuel level. On most concentric-float carbureters the fuel level has been about .06 inches below the jet nozzle. As a consequence of this it is generally necessary to flood the carbureter by priming before starting the motor in cold weather. Other features which are noteworthy are the modified venturi which in this case is merely a constriction in the air passage in the neighborhood of the jet; the interconnection of the auxiliary air and the throttle, high, low and intermediate speed adjustments, free float; connection of throttle to needle valve; taper on needle valve corresponding to air port area and accurate idling adjustments.

Fig. 1 shows the interior of the New-Miller carbureter, a quarter section being cut out on the line of the needle. Through the design of this carbureter, the makers claim it is possible to bring down the vacuum in the manifold to the relative minimum, and, at the same time, take in the charge in such a way that it will not be deflected to either wall of the carbureter or manifold. To accomplish this, the auxiliary air is taken through an annular intake just enough air being taken through the normal to lift the gas out of the vacuum cup in the top of the nozzle.

The throttle butterfly D is connected with a toggle to a pis-

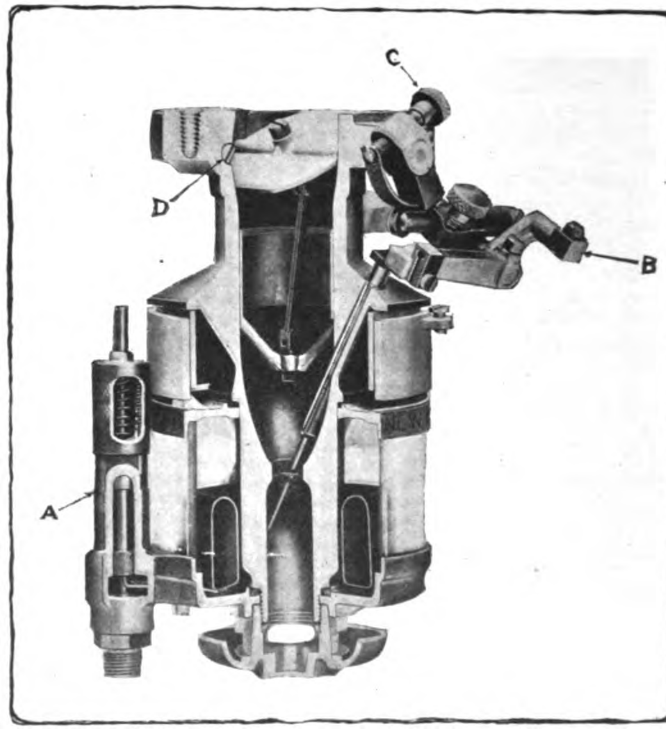

Fig. 1—Quarter section through the New-Miller carbureter showing construction

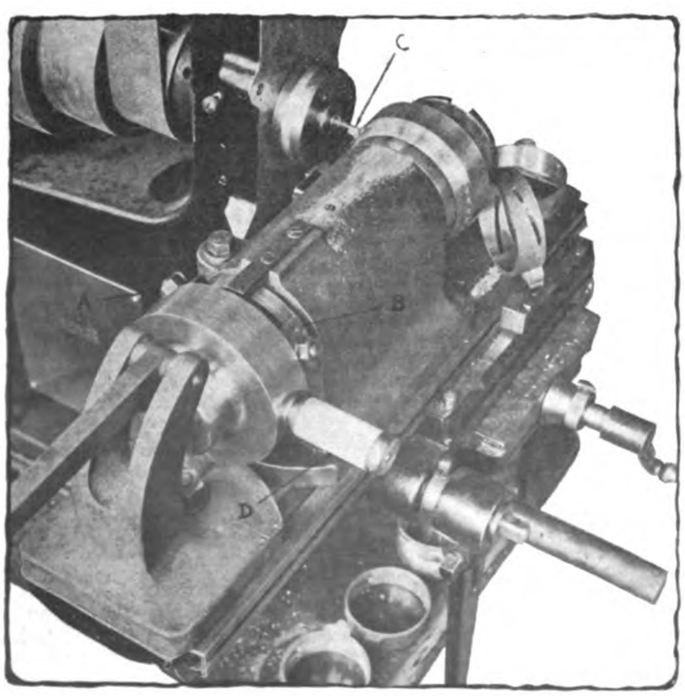

Fig. 2—View of slotting tool especially designed for the New-Miller carbureter

ton that travels over the ports for the auxiliary air. The throttle butterfly is also connected to the needle valve. Every movement of the throttle B has a corresponding movement of the air piston and the needle. In order to give a greater throttle range, the wall around the butterfly is cut on a radius. This gives a much greater range than is possible with the ordinary straight walled carbureter.

The action of the New-Miller carbureter is entirely mechanical, so that the motor, if turning over 1,500 or turning over 300, will receive the same percentage of air and gas at all times. By having the auxiliary air piston connected to the butterfly, it is possible to give the motor a long, hard pull until you have decreased your speed to such an extent that it is necessary to release your clutch and shift gears without loading the manifold.

New-Miller carbureters are all equipped with copper floats, which float free, suspended in the gasoline, until the motor stops, at which time it locks the gasoline. The ordinary method of tilting the butterfly to the proper angle to secure low speed is entirely done away with in this carbureter. The butterfly has one side milled out, and there is inserted in the body of the carbureter at the center of the radius cut for the butterfly a quarter-inch round brass rod with a radius milled on the inside to match the radius of the carbureter. This can be turned down until it will completely close the milled portion of the butterfly or opened to admit just enough gas to secure low speed.

Another advantage claimed by the makers is that it is never necessary to prime, as the float level of the gasoline is the same as the top of the nozzle, or the vacuum cup in the nozzle. To take care of different temperatures and the constant varying grade of gasoline the needle can be raised or lowered from the seat, thereby changing the diameter of the needle in the nozzle while the car is running or standing idle to any desired size and overcoming on the instant any difficulties of this kind.

The New-Miller carbureter has been tooled up to make the parts absolutely interchangeable in five sizes and they are designed for a quantity production of something over 400 daily. Some of the tools for this carbureter are unique in their design. They have been designed by O. L. Snyder, engineer and designer of all the tools in the New-Miller plant.

Fig. 2 shows the cam tool C, for milling the slots in the side of the air sleeve, one of these sleeves standing at the head of

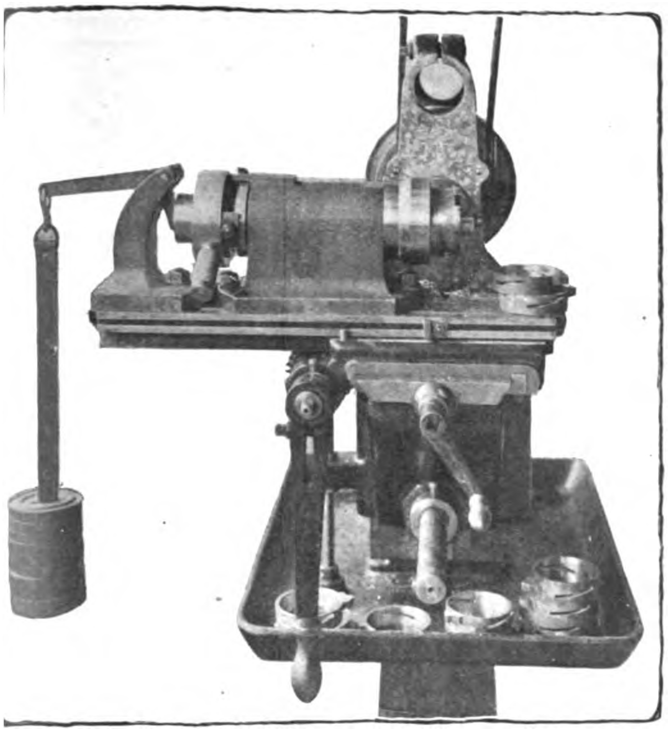

Fig. 3—Rear view of tool used in slotting cams for the New-Miller carbureter

ııs tool showing the slot on each side of the sleeve cut to ıe proper angle. All sleeves are cut on the same degree but ·ith different travels. This tool is also shown in Fig. 3. In ig. 2 the index head is shown. This index head has two zero ıarks at exactly 180 degrees. The head is graduated from each ːro mark 90 degrees on either side. The lock stops B are set ther side of the zero mark to the graduation. On the inside f this case are two master cams fitting into each other, with a ː-degree pitch. The index head is fastened onto a shaft running through the center, the first cam being fastened to the ısing, the other being known as the free cam. This shaft running through connects with the head on the back end holding ıe handle D. This handle is used not only for throwing the ork, but for releasing the free cam underneath. When the ork is set, stops 1 and 2 are set to the degrees on the index ːad. The cutter C is turned through the material, and the stop released and the work thrown over to the opposite stop, when ıe same operation is performed on that side. It is possible to ırn out one of these cams completed every 32 seconds or about ooo per day.

Fig. 3 shows the weights that are used in holding the free ım in against the stationary cam.

Fig. 4 shows what is known as the radius tool. This is for ıtting the radius in the body for the travel of the butterfly. he cutting edge of the tool is set on the same radius as the ıt in the body, the turret being moved up to the stop and the ver used to carry the tool through the work. This tool has a ıpacity of about 40 carbureters every hour, and there are five of ese in operation.

To adjust the New-Miller carbureter, run auxiliary air sleeve › and leave wide open; after you have made all your connec- ›ns for gasoline, leave the throttle closed, turn on your gaso- ıe and adjust your float level nut, the knurled nut above A. ig. 1, so that the gasoline is even with the mark on the stem arked float level. Never above mark. The mark A is at the me level with the top of nozzle. You then start your motor running with the throttle still closed. If steering-post adstment is used, remove nozzle screw; knurled nut above cam . Now raise the cam B forward till engine runs smoothly. It never necessary to prime this carbureter in starting, as the ısoline is always level with the nozzle.

Next adjust the intermediate speed by running the little screw between B and the knurled nut just mentioned, back or forward until the wheel on the roller is about in the position shown in Fig. 1. You can now open your throttle, and adjust the high, by turning to the left which will give you more gas, or by turning to the right, which will cut the gas down.

The intermediate speed is simply an adjustment for your motor to take the high speed a little quicker and for you to ride on intermediate speed with your throttle part-way open, with more or less gas, according to the conditions of the country in which you are driving. The farther out the little wheel is run on the track, the more gas you will have at intermediate speed and the quicker you will take your high on throwing open the throttle. When your high is adjusted properly, you can close the throttle, and the low speed for idle running is seen in Fig. 1, D.

By inserting a screwdriver in the slot D you can turn this to the right until the motor is running as slow as it is possible to get it. You are running then on the idle speed, with nothing but gasoline and what air comes in through the normal opening. When these adjustments are once set, it is never necessary to change them, no difference what the condition of the weather or the grade of the gasoline.

It is the contention of the New-Miller Carbureter Company that in the winter time, when gasoline is very hard to vaporize and when the grade of gasoline goes down, as it does every day, the proportion of air to gasoline must be maintained the same as in warm weather and for a high grade of gasoline, and to do this, the only way feasible is to increase the supply of gasoline. This is accomplished by the steering-post adjustment.

Fig. 1 shows the little cam riding on the lever, and by moving it to the right the needle is allowed to lift out of the nozzle, increasing the diameter of the nozzle thereby. The bottom of the stem of the needle has a taper at the point of entering the nozzle, and on the end of the needle has three butterflies. By lifting the needle the size of the orifice is varied in this nozzle according to how far the taper is taken out of the nozzle or driven down in. In other words, it is possible to put in the smallest needle that is practicable, or increase it to the largest practicable by simply adjusting the steering-post control. The proportions on high, intermediate and low remain just the same under all conditions.

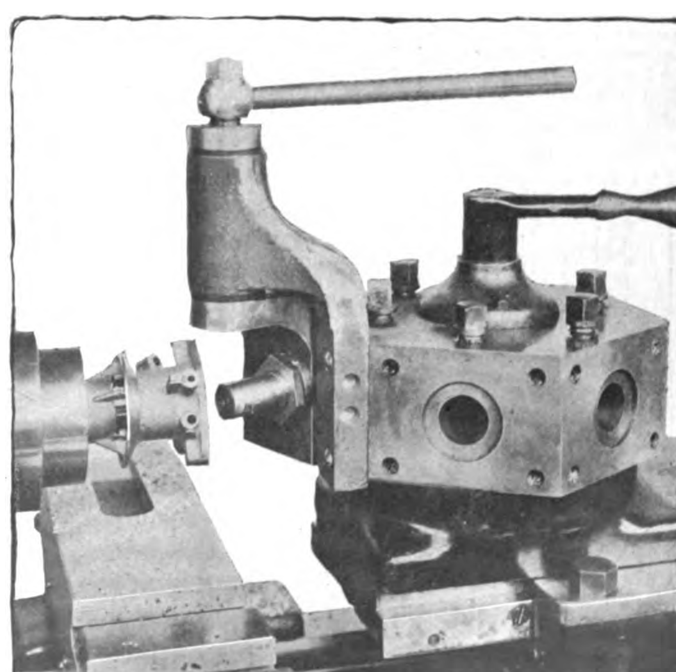

Fig. 4—Tool for cutting radius in body for the travel of butterfly valve

Viso Spark-Plug; Saunders Fuel Saver; Ford Electric Headlights; Seat Covers for Ford Cars; Burke Work-Saving Inflation Valve; Fuel Consumption Gauge; Azadian Indicators; Automobile Gasoline Lock

THE tendency to keep the user of an automobile well informed as to the working of its various parts is well illustrated by the increasing number of spark-plugs equipped with visible-gap features. The latest product developed along these lines is the Viso plug, Fig. 1, made by the Rapp Mfg. Co., Toledo, O. This plug is of conventional exterior, but has two distinguishing features, namely, the visible spark-gap and the adjustability of the jump gap between the two firing points. The visible spark-gap is formed between the top end of the positive electrode and a short point shaped at the lower end of the terminal screw; these two ends are held in a glass insulation which is surrounded by a metal coat resting on the porcelain insulation. By turning the metal coat of the glass, the positive or central electrode which screws in a threaded bearing, may be screwed up or down, thereby varying the distance between it and the electrode formed on the shell. The porcelain is formed without any holes or cavities, to prevent the formation of deposits therein. The spark-plug is made in the standard sizes and porcelain and shell are interchangeable.

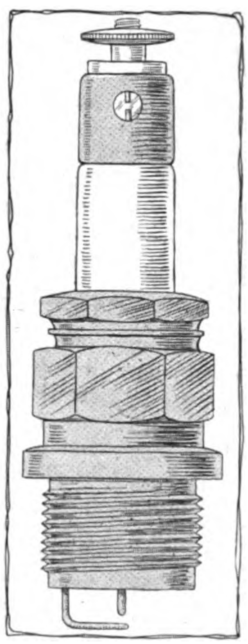

Fig. 1—View of the Viso spark-plug, which is equipped with a visible spark-gap and adjustable central electrode

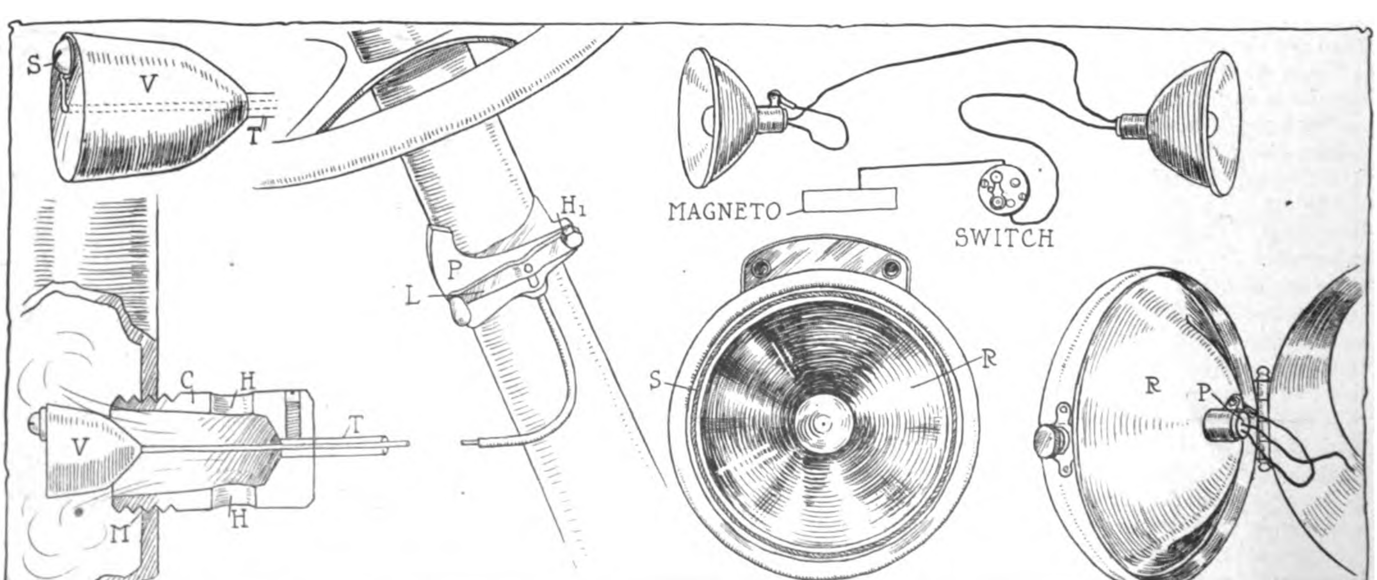
Electric Headlights for Fords

The Motor Car Equipment Company, 55 Warren street, New York City, has recently constructed an electric lighting outfit for Ford cars, Figs. 4 and 5, which consists of a pair of parabolic reflectors fitting into the acetylene lamps furnished with Ford automobiles. In the apex of each reflector is fitted a socket P equipped with connections through which current may be furnished to a bulb B. The reflector R of each lamp is silvered on its concave surface, and the bulb is positioned practically in the focus of the parabola, so that all light is emitted in the shape of a parallel beam. To keep the lens from being scratched the front edge of the reflector is faced with a strip S of white soft material. The wires enter the lamp through the hole in which the acetylene burner is ordinarily mounted. The method of connecting the lamps is shown in the scheme, Fig. 4. The Ford magneto, which is mounted in the flywheel and generates sufficient current to supply a set of lights, is used as the source of electricity.

Saunders Gasoline Saver

To utilize to its fullest extent the gasoline consumed by the motor, the Leslie R. Saunders Company, 927 West Seventh street, Los Angeles, Cal., has evolved the Saunders gasoline saver, Figs. 2 and 3, which is simply a device for supplying auxiliary air to the mixture flowing from the carbureter to the manifold. It consists of a 1.5-inch brass cylinder C, Fig. 2, formed with four air holes H and fitted into a threaded hole M in the intake manifold, thus presenting a pasage from the exterior atmosphere to the interior of the manifold. This passage, however, is ordinarily closed by a conical valve-plug V which, like the cylinder C, is made of brass and exactly fits the inner end of C, thus closing the hole M. Through the apex of C enters a Bowden wire, which passes all the way through V and is fastened by the screw S, while its other end is connected to a small operating lever fixed to the steering column as shown in Fig. 3. The wire is conducted through a tube T leading from the steering column to the manifold, and as the Bowden wire is practically incompressible, a slight movement of the lever unseats the valve V, permitting of air being drawn in through H and M, due to the suction in the intake manifold. The method of fastening the operating lever to the



Figs. 2 and 3—Saunders gas saver and operating mechanism. Figs. 4 and 5—M. C. E. Company's electric lights for Ford cars steering column consists in the use of the brass wire which is wound around the column and the hole H1 in the plate P; this hole is also the point at which the lever L is attached, and around which it may be turned. As the gasoline saver is operated independently of the throttle, it may be brought into action at any time, and used either to increase the air in the fuel mixture after the throttle has been fully opened, or it may be applied as an air brake, when the car is coasting down a hill, with the throttle closed. As a much smaller throttle opening may be used in connection with the gas saver, the saving in fuel effected by its use is appreciable. Except for the tapping of the manifold no changes have to be made in installing the apparatus on an automobile.

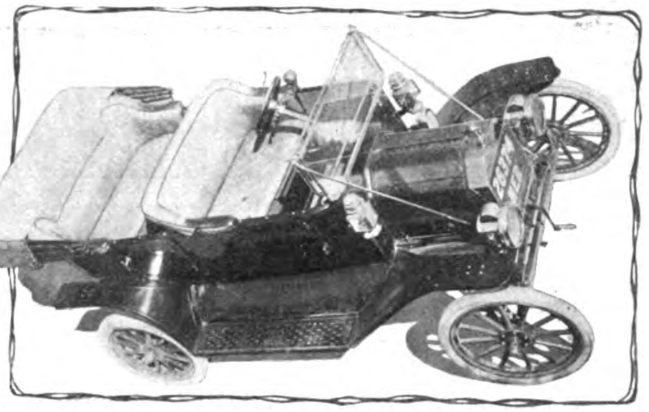


Fig. 6—Reynolds seat covers for Ford cars

Reynolds Seat Cover for Fords

To improve the appearance and to shield the seats of Ford cars against wear, the E. W. Reynolds Company, 713 South Fifteenth street, Omaha, Neb., has undertaken the manufacture of seat covers, Fig. 6. These covers are made of fine, dark brown material cut to fit any model T touring car.

Crary Gasoline Lock

A lock which is interposed in the gasoline line and which serves to shut off the flow of fuel from the tank to the carbureter, is made by the Crary Gasoline Lock Company. This device is illustrated in Figs. 8 and 9. It is a shut-off valve which has a turning play of about 90 degrees and is connected by a flexible shaft to the operating mechanism which may be installed in any suitable position on the dash or floor board. This control mechanism consists of a specially constructed Yale lock, Fig. 8. The valve itself is gas-tight and is said to absolutely prevent leakage of fuel or air. The device may be installed in any suitable position on the dash or floorboard of an automobile.

Holley Fuel Consumption Gauge

The amount of gasoline used per mile should be a point of interest to every automobilist, as it has a direct bearing upon his fuel bills. To enable automobilists to learn what amount of fuel is used by their motors for every mile, under various operating conditions, that is, on the level, on up or down grades, the Holley Brothers Company, Detroit, Mich., have developed the consumption indicator, Fig. 11. The latter consists of a narrow inverted funnel, supported by a frame which is secured to the car, and equipped with a glass gauge communicating with the interior of the funnel-shaped reservoir. In its use, the frame of the indicator is attached to a side-lamp bracket, or to any other suitable part of the dash, and the outlet of the tank which is controlled by a cock is connected to the gasoline supply pipe, while the line from the fuel tank is shut off. The tank is filled up until the floating ball in the standpipe disappears, after which the car is started and sped up to the velocity at which it is desired to make the test. When the ball becomes visible, the odometer is set to zero and the car is run, until the meter registers 1 mile. Now the motor is stopped and the amount of gasoline consumed noted on the indicator scale.

Azadian Line of Indicators

A line of various indicator gauges for use on automobiles are manufactured by the Azadian Gauge Manufacturing Company, Syracuse, N. Y. The line includes water, gasoline, oil, pressure and tires gauges, and a representative product is shown in Fig. 10, this being the Azadian tire gauge.

Burke Minimum-Work Tire Valve

The Burke Valve Company, Cleveland, O., manufactures the tire valve, Fig. 7, which is so constructed as to permit of easy inflation, without the exertion of waste effort. This waste effort, so-called, is the pressure necessary to unseat the ordinary tire valve by compressing the spring holding it to its seat. Assuming the spring pressure against the seat to be 40 pounds, it takes an effort of 40 pounds every time the spring is unseated; in other words, if an ordinary hand pump with a stroke of 1 foot is used for inflation and if a tire is filled with 100 strokes of this pump, 4,000 foot-pounds (.125 horsepower) of work must be spent in opening the valve to permit of all the necessary air being forced into the inner tube. The peculiar construction of the Burke valve is claimed to overcome this evil completely. As Fig. 7 shows, the valve consists of the stem S, which is threaded internally for the valve and externally for the dust cap. The valve mechanism proper consists of a stud V, one end of which is formed as the valve seat designed to retain the valve W. This valve is composed of a plunger, shaped as a piston with air passage through it, which has a reversible rubber valve R at its end; when the latter bears against the sharp edged end of the stud S, the valve is sealed against the internal tire pressure.

AUTOMOBILE SEARCHLIGHT—Having an auxiliary reflector which prevents the loss of light.

The patent refers to a construction as the one shown in Fig. 1, where a main parabolic reflecter R serves to produce a parallel beam of light. In front of the reflector is a burner B emitting the light which is concentrated by the reflector R. An auxiliary reflector R1 in axial alignment with R and positioned in front of B; this auxiliary reflector consists of a double convex lens L, the side remote from the burner being silvered so as to throw all the light it receives back upon R.

No. 1,044,252—to Henry Salesbury and Thomas Whitaker, London, Eng. Granted November 12, 1912; filed July 15, 1908.

Valve Truing Tool—Including a support permitting of free lateral motion.

The subject matter of this patent is a valve-truing device, Fig. 2, which consists of supporting means S for the extreme end of the valve stem, a tool T for grinding the beveled face of the valve and a support S1 for this tool which is formed with a passage P, permitting of free lateral motion of the valve.

No. 1,044,254—to Allan C. Sargent, Westford, Mass. Granted November 12, 1912; filed November 1, 1911.

Shock Absorber—Using an inflated bag in combination with a leaf spring suspension.

This patent refers to an automobile shock absorber which has an elliptical frame F, Fig. 4, including a number of hinged sections S, the adjacent ends E of which are reduced in width. Top and bottom stretches of the frame F are channeled longitudinally at their inner sides, and an inflated bag B positioned between the elliptical frame seats in the channeled portions of the same.

No. 1,043,820—to George S. Foster, Pueblo, Colo. Granted November 12, 1912; filed October 21, 1911.

Muffler Construction—Comprising a circuitous, open pipe, into which the exhaust pipe of the motor discharges and into which air is sucked from outside, thereby silencing the exhaust.

The subject matter of this patent, Fig. 3, is a muffler for internal-combustion motors constructed on a very simple principle. The waste gases leaving the motor by way of the exhaust pipe E are silenced by passing through the circuitous pipe P, which is of substantially equal cross section throughout its length and open at its ends P1 and P2. These open ends are in alignment and arranged with a gap between them; the outlet end E1 of the exhaust pipe E opens into the inlet end P1 of the pipe P, while the outlet end P2 of the latter opens somewhat in the rear of E1. In the wall of the circuitous pipe, inwardly opening check valves are provided which are not shown in Fig. 4, and which open in response to the vacuum created in P by the exhaust gases rushing through it. The mixture of the air and exhaust gases brings about the muffling of the latter.

No, 1,044,157—to Paul Fehde, Berlin, Germany. Granted November 12, 1912; filed July 5, 1911.

Internal-Combustion Motor—In which the valves are actuated from a rocker shaft mounted between two rows of cylinders served thereby.

The internal-combustion motor described in this patent, Fig. 5, comprises a crankcase in which a crankshaft is journaled, carrying connecting rods, the upper ends of which are fastened to pistons which travel in the cylinders C and C1. The latter are arranged in V-manner immediately above the crankcase, with an upwardly divergent gap between them. At the upper ends of the cylinders valve chambers V and V1 are formed, rigidly with C and C1, respectively. These chambers are in rigid relation to the cylinders and formed with seats and directly opposite openings O, which are closed by plugs. Between the inner walls of the valve chambers and the inner upper ends of the cylinders a valve-gear chamber G is formed; a camshaft S is journaled in the lower portion of G, and a rocker-arm shaft above it on which rocker arms A are mounted. Valves W and W1 engage the valve seats formed in the chambers V and V1, respectively, and their stems are engaged by the rocker arms A which operate the valves by a trip hammer motion.

No. 1,044,198—to Alphonse Joseph Lavoie, Outremont, Quebec, Can.. Granted November 12, 1912; filed August 21. 1911.

Hydraulic Clutch Construction—The rotor used in this mechanism is mounted eccentrically and is shaped with radial impelling blades.

The subject matter of this patent is a hydraulic clutch including a casing which forms a fluid chamber, the latter containing an eccentrically mounted rotary piston. Radial blades are slidably mounted in the piston, and project at opposite sides thereof, against which resilient rings are loosely fitted. These rings act on the projecting portions of the blades. A conduit is formed in the casing, adjacent to the principal chamber formed in it and connected to it at spaced points, the capacity of this conduit being variable by the operator of the device.

No. 1,043,617—to Horward L. Manley, Kansas City, Mo. Granted November 5, 1912; filed January 15, 1912.

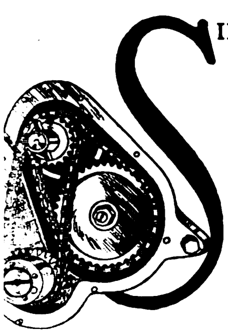
VOL. XXVII NEW YORK—THURSDAY, NOVEMBER 28, 1912—CHICAGO No. 22

The AUTOMOBILE

Skillful Work Is Silencing American Motors and Chassis

Attention to Detail Is Eliminating Lost Motion, Gives Reduced Wear and Promotes Quietness—Rattling Accessories Are Among Noisy Nuisances

Working to Close Limits the Surest Cure in Many Cases—Cam Design of Utmost Importance—Use of Spiral Gears, Silent Chains, Etc., Increasing



SILENCE of action marks the ultimate refinement of a machine. Noiseless action once secured, it only remains necessary to use proper materials to perpetuate this condition. The steps made by American designers toward securing a quiet running motor have been particularly marked during the past few years and this advance has gone hand in hand with advances in metallurgy—the art of selecting the proper metal for the proper place. To the casual observer the noises issuing from the different parts of the car combine into one inharmonious whole, but to the trained ear the chorus is dissected and each component hiss, groan and squeak is assigned its proper place.

In the motor there are four prominent sources of noise: the valve action, timing gears, magneto drive and carureter. These parts can be segregated and treated separately. 'he noise of one has no bearing upon the noise of the ther.

In answer to the question, "What have you done to silence our valve action?" THE AUTOMOBILE received a series of nswers from the most prominent engineers throughout the ountry showing that, although the means differed, the earnest ttention of the engineering staffs was turned toward a study f this particular part of the motor.

The valve action of the poppet-valve motor can be sepaated into the cam, follower mechanism, tappet and valve.

The root of the noise evil in the valve action has been traced the cam. This presents a problem which engineers have not et reduced to such a point that they are unanimous upon the oint as to which is the best cam for all around use. There e two causes of cam noise, first, the striking of the side of the m against the follower, and, second, the striking of the folwer against the cam due to the fact that on the down stroke the valve at high speed the cam runs away from the folwer for a brief interval and then the latter strikes it with fficient impact to create a sharp tap. With a cam so designed at the follower never leaves it, it is evident that this noise dispears. At the same time, however, this means a slower

Fifteen Silence-Producing Points That Are Becoming General Practice

- Designing cams that give power with silence.
- Using helical gears in the timing set.
- Replacing gears by silent chain and sprockets.
- Inserting felt and fiber pads at contact points.
- Reducing clearance at valve tappet to .003 inch.
- Fitting cover plates over parts that are noisy.
- Using leather, springs and rigid keys in magneto drive.
- Limiting backlash in gearset from .001 to .003 inch.
- Employing aluminum and other non-resonant metals.
- Making gears solid to eliminate bell action.
- Putting accessible adjustments on rear axle.
- Using worm drive in place of bevel gears.
- Fitting spiral springs to compensate for wear.
- Firmly attaching lamps, horns and other accessories.

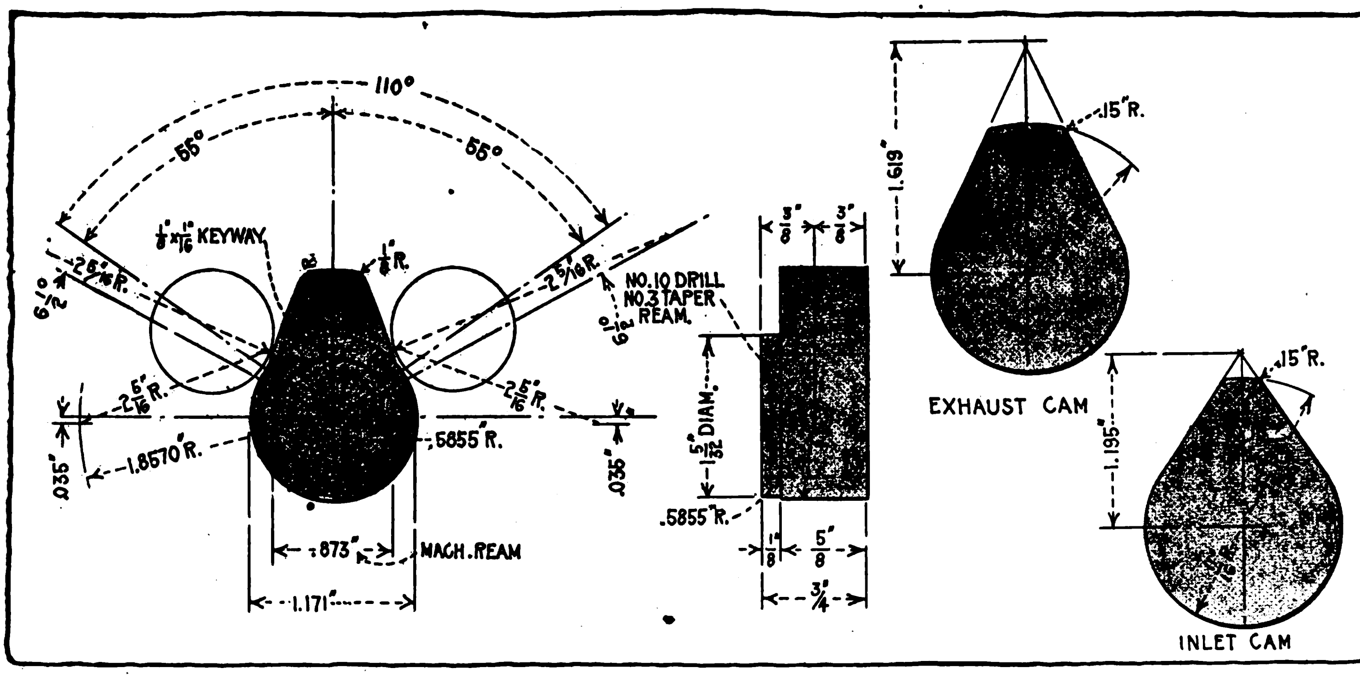


Fig. 1—Left, full working drawing of a straight-sided cam. Right, illustrating difference in intake and exhaust cams

movement of the valve and consequently an appreciable falling off on power. The maximum power is secured with the flat-sided cam giving quick opening, closing and—noise. One maker states, "Our touring cars are much more silent than our speedsters and racing cars because we are able to make a cam of more advantageous shape, the opening and closing of the valves not being as sudden." Another, who uses the cam design shown at the right of Fig. 4, states, "You will notice that there are no flat spots on the profile and hence, by keeping close to the limits, we are able to secure quietness in operation."

A study of Figs. 1 and 4 gives an idea as to general practice. Neglecting the variations in the shape of the cam due to the difference in valve timing of the different motors, the factors which determine the contour are the type of linkage used, the function of the valve, whether inlet or exhaust, the lift and diameter of the valve and their relationship, piston displacement per unit of time of the motor, and, it may be added, the purpose of the motor, although perhaps this latter is taken in with the others.

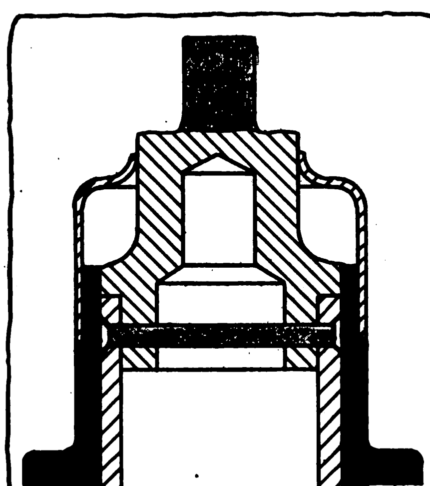

Fig. 2—Valve lifter; note light construction

Although all other parts of the valve mechanism may be interchangeable, the exhaust and inlet cams must be different. This may readily be perceived if the action of the exhaust gases is taken into consideration. There must be a sufficiently large opening of the valve when it is first released to allow the pressure to drop to atmospheric before the piston starts on its up, or true, exhaust stroke. If not there is a considerable loss of power. This means a sudden and quick opening of the exhaust valve and hence a steep cam. Note the contours of the exhaust cams in Fig. 1. These are examples of a quick opening. In comparison with this the enlarged exhaust cam in Fig. 4 may be studied. The tangent lines are drawn from the point at which the valve starts to open and are hence a measure of the slope of the cam at this point. The further away the intersection of these two is from the center of the cam, the earlier the opening.

It is evident that a flat-sided cam, such as that shown in Fig. 1, will give a quicker opening than the rounded cam shown in Fig. 4. It is also evident that the noise which accompanies the overcoming of the inertia of the valves and linkage will be greater with this flat-sided cam because the clearance is taken up more suddenly. The two cams in Fig. 4 have been enlarged to show the relation between the cam contour and the clearance which is laid out in the dotted circle surrounding the cams. When the cam comes into action, the distance between the surface of the cam and the clearance circle will be zero. For the sake of simplicity, let the clearance as outlined in the clearance circle, Fig. 4, represent all the clearance in the mechanism. That is, between the cam and follower, as well as in the component linkage. Supposing for the moment that the side of the cam is absolutely flat, as is the case in racing cars, where noise is no objection and power the object. The impact of the cam on the follower is resisted by the weight W of the whole valve action as well as by the pressure P of the gases within the cylinder upon the valve head and the tension of the valve springs. The factors W and P are referred to later.

This shows the tremendous hammering effect produced by the flat or straight-sided cam. Taking the force of the blow as even 10 pounds, however, it can be readily perceived that the noise of a metal-to-metal contact at any speed would be considerable. This neglects such features as bad adjustments between stem and tappet, etc. It is a question of power versus silence.

Before leaving the subject of cams, one more cause of cam noise should be considered. It is just as important to have a quick closing as opening. The valve cannot be closed any more quickly than the spring can act. If the cam runs away from the follower when the valve begins to close, the follower will impinge upon the cam immediately afterwards giving a hammer blow which is a noise producer. This is a question of cam and spring design. The springs must be heavy enough to keep the follower on the cam, the cams must be of such design that they do not necessitate too heavy a spring to keep the followers upon them and finally the springs cannot be so heavy that they consume too much power and necessitate too much energy in lifting them. The latter fact is of particular importance in that it is a distinct factor in the noise and hammer effect in the opening of the valve.

Engineers and designers are trying to get the power-giving cam and silence at the same time by using non-vibrating and cushioning materials. Fiber lends itself to this purpose with more success than most other materials, although the use of felt washers between contact points has had considerable success and is a growing practice.

So far no mention has been made of friction in the valve mechanism itself. Friction is important because it is an indirect cause of increased noise. It increases the factor W in the impact formula. Friction depends upon three things: First, area of contact; second, quantity and quality of lubrication; third, pressure between bearing surfaces. Taking these up separately the area of surface contact may be first mentioned. Friction is included in the factor W and directly affects the inertia.

Actual contact will only exist between the lifter and guides and the valve stem and guides. Other contact than this can be neglected. Taking the valve lifter, for instance, a general type of which will be seen in Fig. 2, the first consideration is that there must be sufficient bearing surface to take care of the side thrust due to the side component of the thrust delivered by the cam to the lifter when the cam acts directly upon it. When the thrust is delivered through a follower and other linkage the side thrust is practically eliminated, although other factors enter. Oil leakage is also to be guarded against and a long guide aids in this. The illustration represents general practice. The length of the valve stem guide must be sufficient to prevent leakage and must be arranged so as to be adequately cooled to prevent sticking.

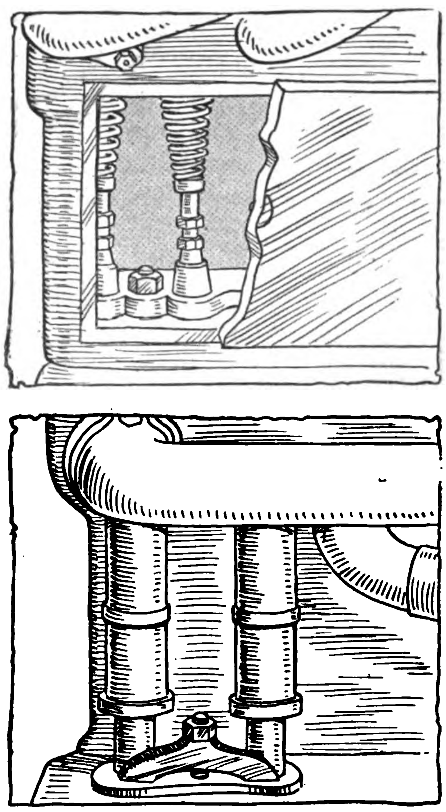

Fig. 3—Upper, cover plate for two valves. Lower, independent cover tubes

Lubrication of the followers will present no difficulty. Indeed, the trouble will be the other way, as there is a marked tendency for the oil to leak through the guides and down the side of the crankcase. Fig. 2 shows the light metal cap generally used to guard against this.

Pressure between bearing surfaces is due in the case of the following mechanism and in the tappet guides by side thrust and by the weight of the parts. All parts of the valve mechanism should be as light as possible. The principal reason for this, however, is to cut down the factor W in the equation for inertia mentioned above.

Admitting that a certain amount of noise throughout the valve action in the poppet type is a necessity, it is interesting to note what means are taken to render the sound inaudible to a person sitting in the car. Fig. 3 shows two methods of inclosing the valves. The upper illustrations show a method that is growing in favor. It is, in fact, an individual housing over each spring and tappet. The lower illustration shows the more popular form of housing. This is a complete housing for the entire side of the motor, or, where the cylinders are cast in pairs, the housing extends over each pair of cylinders. Aluminum or other non-resonant material is used here.

What used to be a prolific source of noise are the timing gears. Spur gears which do not mesh as well as they should produce a grinding hum that stands out

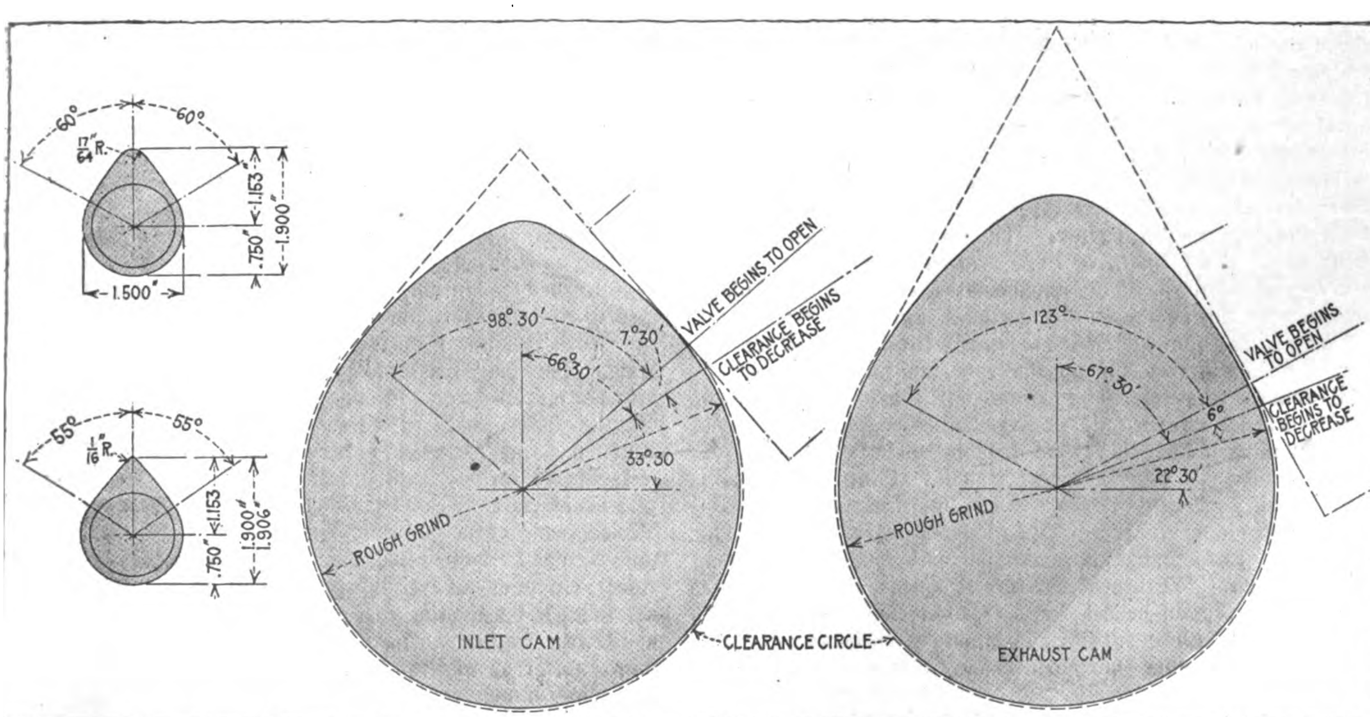

Fig. 4—Left, curved exhaust and inlet cams. Right, enlarged view of cams, showing clearance circles

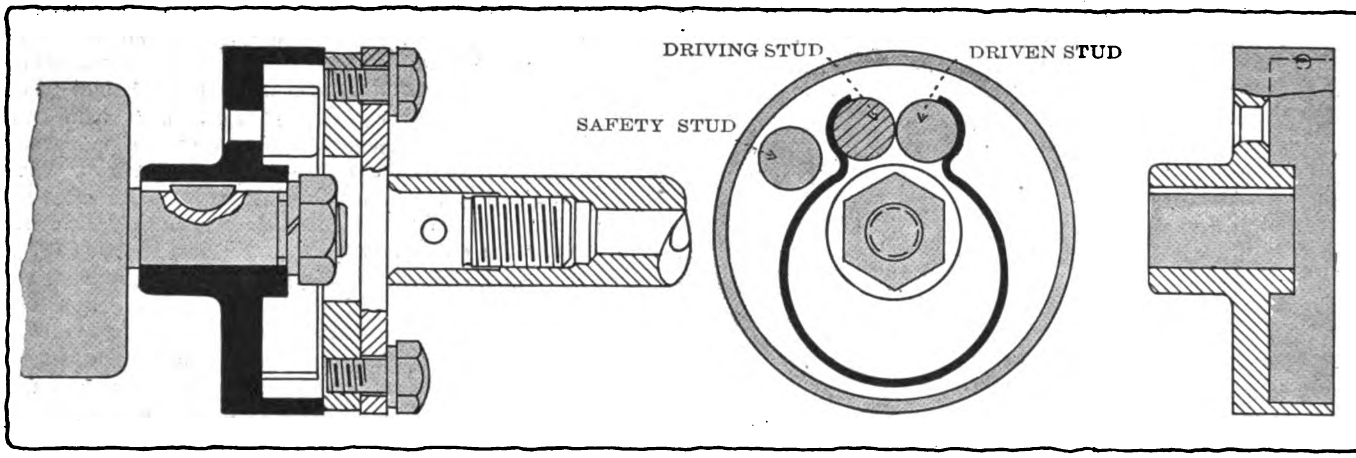

Fig. 5—Side and transverse sections of spring magneto drive and a side section through feather type

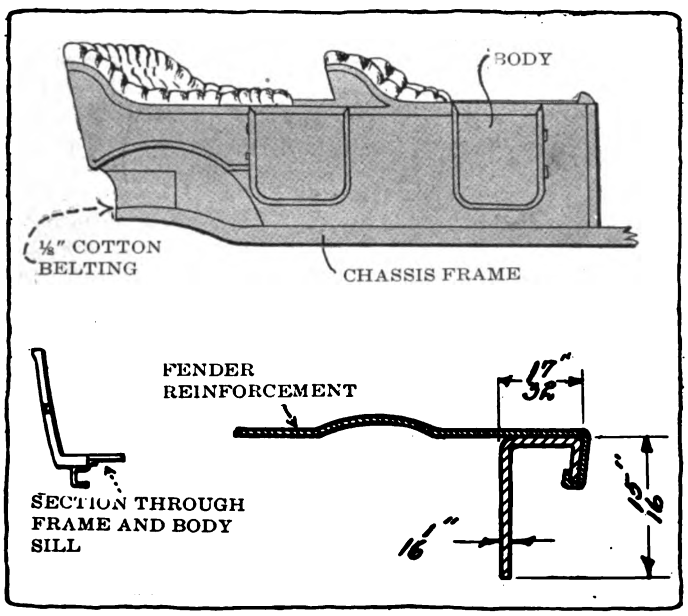

Fig. 6—Means taken to eliminate body and fender squeaks

above the other noises as black against white. Three methods are now used to overcome noise in this part of the mechanism: Improved methods of manufacture of spur gears, the use of spiral gears and silent chains. It may be stated here in reference to the improved methods of gear manufacturing that owing to the competition of the silent chain and the spiral gear and other devices the manufacturers have been compelled to focus their attention on this matter. The result is that they are all grinding to closer limits or have changed over to the helical gears or chain drive. The statements of some of the leading engineers on this subject in response to a canvass by THE AUTOMOBILE are as follows: "We are using helical gears which are almost noiseless even though they are not meshed properly." "All timing gears are cut twice and any that vary more than .00025 inch are thrown out." Several other engineers gave this as the limit to which they were grinding their timing gears of the spur type. Another engineer stated that the timing gears used by his concern were made silent by "using a steep angle spiral and holding the eccentricity of gears below .001 inch and fitting the gears so that the maximum back lash is .003 inch." Another states, "We use a cast iron against a steel gear, both of which are cut in helical shape." Other engineers state that they limit back lash to .001 inch; maintain center distances to .001 inch; and many other statements tending to show that the care in manufacture has increased. In one case the engineer of a large factory claimed that he was obliged to adopt a gear of not greater than 15 degrees angle of spiral with 10 pitch on account of an electric starter which operated through them. In his opinion, however, the 29-degree spiral was much more silent.

The engineer of a concern using a chain-driven timing set states that they were obliged to adopt a chain larger than that recommended by chain manufacturers for the reason that the smaller sizes would not stand up under a heavy load. To further produce silence with these chains they are using a composite fiber sprocket for the magneto gear to reduce the hum.

The above shows that in many cases it is a question of improved manufacture rather than changed design. The old type of motor with its ill-fitting pistons, rings and bearings was noisy and would not stand up because there was too much lost motion. The tendency towards cutting down the limits of tolerance was greater during the past year than ever. The cry for close grinding work from the engineer was responded to by the workman and tool maker to a remarkable degree. Ringing gears are becoming unknown. The solid gear eliminates the bell action of the lighter designs and cures another source of noise.

Many magneto couplings are noisy. The old style of Oldham coupling was particularly troublesome in this respect, starting to rattle as soon as a small amount of play developed. The magneto drive of today is through a coupling which compensates for the lost motion as soon as it occurs, in other words, the drive is through a spring. For the sake of illustration a detailed drawing of one form of magneto coupling is shown in Fig. 5. As may be seen from the lettered view, the drive is through studs. The spring, shown in black, holds the driving stud against the driven stud in spite of any wear that could occur between these two studs. The safety stud is to take care of the coupling in case of any breakage of the spring. The side section is shown to the left of Fig. 5. As may be seen, the drive is taken up by the magneto through a No. 3 Woodruff key furnished on the magneto shaft. A simple form of keyed magneto connection is shown in part section at the right end of Fig. 5. A prominent magneto concern uses a laminated flat spring. The drive is directly through this spring, which is located transversely on the end of the drive shaft, and engages with the driven shaft by means of a slot through which the laminated spring passes. The flexibility is thus gained through the laminated spring. Leather couplings are also used and give great satisfaction. They have met with great favor in Europe.

Noises which emanate from the gearset are prevented in the same manner as those which exist in the timing gears, with the evident exception of spiral gears. The use of non-resonant materials for the housing is a particularly valuable feature here, but the true way of curing noisy gears is by working to closer limits. Accuracy of gear cutting is one of the first requisites of a quiet-running motor. The rear axle is the same. Where the limit formerly was .002 inch it has been reduced to .00025 inch in many of the best factories. It is a significant fact that evel-gear rear axles became noticeably more quiet as soon as ıe worm drive began to make itself felt as an important con- ːnder on account of its silence. It has been the same story ver again of the valves. When the sleeve-valve motor began) cut such a wide swath in the industry immediately the pop- et-valve makers fought back with the same weapon—silence.

Noise in the gearset is generally found on the first and re- erse speeds. This is natural owing to the larger number of ːeth in engagement and hence for the greatly increased chance f back lash. Noise in the rear axle is not so apt to be apparent ·hen the car is new as after it has been run for about a month. : is then that the noise which was at first concealed perhaps by heavy packing of grease begins to make itself felt. In order) get away from this makers are preparing tests on the rear xles which bring out every weak point. One maker says, "Our ːar axles are coupled to a dynamometer and driven by means f an electric motor for a considerable time before being placed ı the car. They must pass inspection for silence before being ːcepted." The testing room is the greatest factor in securing lence there is. Its power of accepting and rejecting should be ıd is absolute in a large factory.

Spring leaves and bolts should receive more than the modi- ım of attention that is sometimes the case. The fitting and brication of the bolts has received special attention in one fac- ıry where they have fitted a wick within the bolt. The oil is ːd to the bearing surface by capillary attraction and it is aimed that one filling will last for 1,000 miles. Integral grease ıps, etc., are old institutions, but are still being fitted to care- ılly designed cars. In connection with remarks on spring ›lts it may be said in passing that there are makers who be- ːve that spring bolts, built as specified by S. A. E. standards, ·e too tight to permit of good lubrication and hence give rise) squeaks.

Chattering brakes are not as common as they were at one me. The customary attaching of drag springs to keep the ıoes free of the drums under running conditions is sat- factory. It may be stated that the linkage is noisy at times, ɔwever, and this is prevented in many cases by the intro- ıction of spiral springs which take up the rattle.

Probably more rattle issues from the miscellaneous gear ɔout the car than from the motor and running gear put to- ether. The sketches in Fig. 7 show some of the ingenious ıethods in use to suppress these rattles. At the top right is ıown at A and B the two coil springs fitted in the floating ıember of the universal joint. This construction does not ıtail much expense and certainly makes for silent running. he same car is fitted with a rubber block in connection with ıe torsion lever bumper link; this is shown just below the niversal joint floating member. Rattling drag links are ɔmmon after a car has been run more than 10,000 miles. 'ne maker gets away from this by putting in a spiral spring, ; shown at the left end of Fig. 7. Adjoining this sketch is nother showing the use of a spiral spring which will elimi- ate the rattle of the bottom pan very effectually.

A particularly frequent source of noise is to be found in the fitting of windshields. These are often fitted by two or three brass clips which hold them to the dash. The clips are sure to work loose after a time and the result is that the windshield is free to move over the dash, creating a squeak which is distinctly audible. The attachment shown in Fig. 7 with a rubber pad between the dash and the shield silences one source of squeak effectually, while the other source, between the dash and the shield, is prevented by lapping the filler board over the dash. Lamps can make a very disagreeable rattle, but not when fitted into the top of the dash cowl, as shown in the lower right corner of Fig. 7.

All the squeaks issuing from the poor mounting of accessories such as horns, speedometers, lamps, license plates, trunk racks, tire brackets, etc., cannot be compared to the squeak which will issue from a badly mounted body. The use of a layer of anti-squeak material between the frame members and the body is universal. This is placed as indicated in Fig. 6. It generally consists of woven cotton belting or sometimes rubber or felt. A tight connection between the body and frame is naturally imperative for other reasons than silence. Reinforcements throughout, however, are good noise preventers and not the least of these is the fender reinforcement as shown in Fig. 6. Where it is not a case of silence versus power, as it is in many parts of the car as pointed out, good workmanship is the answer.

THE AUTOMOBILE wishes to extend its thanks to the many prominent engineers who have kindly furnished information showing the present practice in their respective plants and the means employed in approaching the problem of silence both in its entirety and in detail.

Receivers of U. S. Motor Co. Announce New Manager of All the Properties Emerging From Bankruptcy

Another Spark Plug Suit—W. C. P. Settlement Approved —Grabowsky Company Bankrupt—Other Trade News

ANNOUNCEMENT made Tuesday by Robert Walker and W. E. S. Strong, receivers for the United States Motor Company, makes public the appointment of Walter E. Flanders as manager of the company and its five factory subsidiaries for the receivers and W. F. McGuire as assistant manager. They will have authority over all departments of the company except the auditing, accounting and treasury, which will be operated for the present by the incumbent forces.

For various reasons there has been considerable delay in getting started on the manufacturing schedule of the Maxwell plants but the receivers have just announced that the preliminary work has been concluded and that the flotation of the $1,500,000 of receivers' certificates will be undertaken shortly. It was found that another inspection of the plants had to be made and this served to delay proceedings.

Practically 96 per cent. of the claims against the company have been filed with the designated depositary and the time for depositing stocks has been extended until December 15, when it is expected that about 60 per cent. will have been impounded.

The course of the procedure has not all been smooth, however. Suit has been entered against the company in the New Jersey branch of the United States District Court on behalf of three creditors whose claims aggregate about $5,000. The grounds for the action apparently are that the New York suit is invalid because the complainant company, the Brown & Sharpe Manufacturing Company is a Rhode Island Corporation and the United States Motor Company has its legal existence in New Jersey. The apparent theory of the complainants in this case is based upon the same assumption as was the demurrer to the court's jurisdiction which was informally filed in the New York suit. Judge Hough disposed of the claim by stating from the bench that in his opinion, he did have jurisdiction. Whether or not there is any element of contempt of court in the New Jersey suit is a question that has stirred up considerable interest in New York.

Spark Plug Repairs To Be Tested

Suit has been entered in the United States District Court by the Rajah Auto Supply Company against the American Auto Supply Company charging infringement of the Mills patent 825,856, covering porcelain spark-plugs. While the patent itself forms the basis of the suit, the main contention is that the defendant company made a practice of advertising and selling the porcelain parts of spark-plugs with which to repair Rajah plugs.

The suit raises an interesting point of law somewhat similar but much more limited in its scope than the point involved in the famous Dick Mimeograph case. The Rajah people claim that under their patent they have the right to insist on repairing their own plugs, using a patented material. In the Dick case the Supreme Court held that the patentee had the right to control the use of unpatented material with the patented device. Newell and Neal represent the Rajah party.

Court Approves W. C. P. Settlement

Following favorable action by the creditors of Wyckoff, Church and Partridge, Inc., the United States District Court has issued an order approving the sale of the assets of the embarrassed corporation to Chester Griswold, Howard C. Dickinson and George W. Ellis. The assets will be turned over to the committee on Saturday. The creditors receive $150,000 in cash in addition to certain credits that have been marshaled by the receiver, John S. Sheppard, Jr., which amount to between $20,000 and $30,000. All told the settlement means something over 27 cents on the dollar.

The claim against the Driggs-Seabury Ordnance Corporation and the counterclaim of that company together with the property of Wyckoff, Church and Partridge, Inc., held by the Driggs-Seabury company are not considered in the settlement. The attornews who have handled the matter state that the elements of the controversy will approximately balance.

A corporation to continue the business is in process of formation and its details will be announced subsequent to the actual consummation of the court action.

John S. Sheppard, Jr., has been named as trustee for the creditors.

Grabowsky Company Bankrupt

DETROIT, MICH., Nov. 25—The Grabowsky Power Wagon Company was adjudicated a bankrupt by Judge Tuttle, in the United States District Court on November 22. The concern will be operated by the receiver, the Federal Trust Company, until December 5, when a meeting of the creditors will take place, at which bids for the plant and equipment will be considered.

Receiver Named for Poss Company

DETROIT, MICH., Nov. 25—Affairs of the Poss Motor Company were brought to a head last week with the filing of a petition in the United States District Court before Judge Tuttle by the

Automobile Securities Quotations

THE stock market was strong again last week with Goodyear's continued advance the feature. This stock shot up $38 a share on a few bids and fewer sales, making another new mark at 450. Firestone also showed great strength, being marked up 5 points over last week's level. Goodrich declined a point on the New York Stock Exchange and the other tire companies were steady.

Detroit Foundry Company and several other creditors, to have the Poss concern adjudicated a bankrupt. E. H. Rogers was appointed receiver, and the case referred to Lee E. Joslyn.

It is claimed by the petitioners that the Poss company is insolvent and that the plant has not been in operation for the past 3 or 4 months. It is further claimed that a number of judgments have been filed against the concern.

The Poss Motor Company will contest the granting of the petition when it comes up in court again within 2 weeks, on the ground that with the help of the major creditors' committee which is now engaged with its affairs, it can be set on its feet. Reorganization plans are at present under way. It is stated that $150,000 new capital is needed and that half of this amount was in sight when the petition was filed by the minority creditors.

It is further contended that the truck is a good one and can be sold as fast as manufactured, and that additional capital is what is needed to make the concern a paying proposition.

Durant Heads Chevrolet Company

DETROIT, MICH., Nov. 25—The following officers were elected at a recent meeting here of the board of directors of the Chevrolet Motor Company, Flint, Mich.: W. C. Durant, president; J. D. Port, vice-president; W. H. Little, second vice-president; Dr. E. R. Campbell, treasurer; C. R. Hathaway, secretary; W. M. Murphy, assistant secretary.

Daimler Import Assets Very Small

Schedules in bankruptcy of the Daimler Import Company show liabilities of $67,261 and assets of $4,626.. The latter consist of an automobile, spare parts, accounts and a bond for $2,000. The liabilities consist of claims by Lawrence F. Braine and the New Netherlands Bank, H. A. Content and others.

Market Changes of the Week

FEW changes took place in the markets last week. Antimony, Bessemer steel, copper electric, lead and scrap rubber had changes. Antimony dropped $.00 1-8 on Thursday, closing at $.08 7-8. Bessemer steel dropped $.50 on Monday, due to poor trading, closing at $27.50 per ton. Copper electric suffered a material change of $.00 1-10. Lead dropped $.10 on Thursday, closing on Monday at $4.50 per 100 pounds. Tire scrap declined on Thursday $.00 1-8 and remained at that figure throughout the rest of the week, closing at $.09 7-8. Copper lake, open-hearth steel, petroleum, and tin remained constant. In the chemical market sulphuric acid and cyanide potash remained at their old figures of $.99 and $.19 respectively. Gasoline, linseed oil, rapeseed oil and lard oil offered no material changes in prices, closing at $.21, $.52, $.73, and $.96 respectively.

Huber Case in Spotlight

Patent Trial Interests Detroit Industry—Packard Adds Three More Buildings To Its Factory Plant

Five Manufacturing Companies Announce Changes and Promotions Affecting Their Department Heads

DETROIT, MICH., Nov. 25—Preparations for taking testimony in the Emil Huber three-point suspension patent case brought by the North American Vehicle Company, owner of the patent, against the Detroit Taxicab and Transfer Company, which is being defended by the Kelly Motor Truck Company, maker of the trucks operated by the Taxicab concern, are now under way. R. A. Parker, attorney for the plaintiff, states that in all probability the case will be begun in about 2 weeks, or as soon as the models which he is having prepared are completed. It will come before Judge Tuttle in the United States District Court in this city.

Changes in Michigan Factories

DETROIT, MICH., Nov. 25—The past week has seen a number of changes among the department heads of various Michigan factories. Among the more prominent are the following:

E. A. Nelson, chief engineer of the Hupp Motor Car Company, has resigned that position to take up consulting work. His position will be taken by his former assistant, F. E. Watts, while D. T. Hastings, formerly with the Packard company, will assume the duties of assistant engineer.

The Cass Motor Truck Company, Port Huron, Mich., has engaged E. J. Farkas, formerly chief engineer of the Cartercar Company, Pontiac, Mich., as consulting engineer. He is at present engaged in developing a line of trucks for the concern.

J. J. Ramsey has become vice-president and treasurer of the A. C. Knapp company, body makers. Mr. Knapp's former connection was with the E. R. Thomas Company, Buffalo, of which he was secretary and treasurer.

The Olds Motor Works, Lansing, Mich., now has E. R. Van Linden as its factory manager, G. D. Baker, who formerly held that position, having resigned to become manager of the Diesel Engine plant, Ghent, Belgium. Mr. Van Linden held a similar position with the Buick plant No. 1, at Flint, Mich.

The Flanders Motor Company has added W. F. McGuire to its staff as production manager. Owing to ill health Mr. McGuire resigned last spring from a similar position with the Ford Motor Company.

Packard Adds Three New Buildings

DETROIT, MICH., Nov. 25—The Packard Motor Car Company has enlarged its factory plant to the extent of three new buildings which are now in the course of construction. They are to be entirely of steel, concrete and glass and are in line with the company's policy of shop units. The Packard company already has 37 acres of floor space, and these new buildings, which bring the number up to thirty-three, will swell the acreage to about forty. About 7,000 men are at present employed at the plant, the weekly pay-roll amounting to about $500,000.

DETROIT, MICH., Nov. 23—The Gearless Differential Company has been incorporated with a capital stock of $20,000 to manufacture a patented differential device which is claimed to do away with gears for this part of the rear axle. A system of ratchets and rollers is employed. The incorporators are: Frank Howarth, G. D. Bailey and W. N. Trudean.

Warren Board Is Enlarged

Directors' Committee to Consist of Nine Members—First Solid Tire in West Built at St. Louis

Ohio Answers Insolvency Suit—Foreign Trade Will Pass $4,000,000,000-Mark Before the Year Ends

DETROIT, MICH., Nov. 25—At a meeting of the directors of the Warren Motor Car Company, several changes were made in the personnel of the concern. Homer Warren was re-elected president; C. R. Wilson was made vice-president; F. T. Lewis, secretary, and L. M. Hamlin, treasurer. R. W. Allen, formerly secretary of the organization was made general manager and assistant secretary and treasurer.

Under the reorganization, the directors' committee consists of nine as follows: Homer Warren, C. L. Wilson, C. H. Wilson, H. H. Bassett, S. G. Jencks, F. T. Lewis, John Mowe, G. Jahn and L. M. Hamlin. This committee is at present working on a trust agreement which will be submitted to those interested about the first of December.

First Solid Tire Built in West

ST. LOUIS, Nov. 25—The St. Louis Tire and Rubber Company, which was organized recently in this city turned out the first solid tire Saturday. This is the first solid rubber automobile tire to be made west of the Mississippi River.

J. A. Swinehart, who is vice-president and general manager of the new firm, stated that the company obtained possession of the building November 6, broke ground for the engine on the same day, unloaded all the machinery from the cars, placed same in running order and turned out a tire in 17 days.

Mr. Swinehart stated that there is no foundation for the report that the St. Louis concern is a branch of the Swinehart Company, of Akron.

Ohio Answers Insolvency Suit

CINCINNATI, O., Nov. 25—The Ohio Motor Car Company, against which the Eisemann Magneto Company and other creditors brought proceedings in involuntary bankruptcy a few weeks ago, has filed its answer denying that it is insolvent or that it has committed any act of bankruptcy as charged. A demand is made for a hearing before a jury. President C. F. Pratt, upon the authority of the board of directors, made the answer. Great efforts are being made to reinforce the Cathage plant. It is thought that the bankruptcy matter will be cleaned up the same as it was 2 years ago. According to a rumor, West Virginia capitalists have offered $600,000 for the plant.

Foreign Trade Over $4,000,000,000

Preliminary estimates of the foreign business of the United States for the calendar year of 1912 indicate that the aggregate will be not far from $4,000,000,000. This will be divided into exports, $2,300,000,000, and imports, $1,800,000,000. The big exports of grain may raise the total of out-bound shipment above the figures given. Imports have doubled in value since 1901 and exports since 1904.

Mais Factions Fight for Dividend

INDIANAPOLIS, IND., Nov. 25—Stockholders and creditors of the old Mais Motor Car Company are making a lively fight in the Superior Court in Indianapolis to determine which shall receive about $80,000 which is in the hands of Franklin Vonnegut, received for the concern. The property and business of the company was sold some time ago to a reorganized company by the same name, headed by Frank H. Wheeler.

When the company was in debt about $180,000 and before the receivership proceedings had been brought, creditors agreed to an extension of time if they should receive a payment of $75,000. The company raised $67,000 in cash and a note for $8,000 and paid the money to the creditors.

The stockholders now claim that the creditors were to receive nothing unless they received the full amount of $75,000, and that the payment of $67,000 was therefore illegal. They also claim they have a trust interest in the money in the receiver's hands.

Palmer Factory Nearing Completion

DETROIT, MICH., Nov. 23—The Suburban Motor Car Company, which has in construction an automobile factory at Ecorse, a suburb of Detroit, has been reorganized under the name of the Palmer Motor Car Company, of which R. A. Palmer, former general manager of the Cartercar Company, Pontiac, Mich., is vice-president and general manager. Mr. Palmer is also president of the Palmer-Bee Company, dealers in power transmission machinery and factory equipment.

The Ecorse plant is about half completed and it is hoped that it can be finished so that manufacturing may be commenced the first of the year, at which time announcement of the type of cars it contemplates building will be made.

W. A. DeSchaum, who designed the Suburban car, will not be connected with the concern.

Underwood Metal Bill as Revision Basis

The Underwood bill revising the tariff on metals, which was passed by both houses of Congress early this year and which encountered the veto of President Taft, will probably form the basis of the new legislation to be adopted at the special session of Congress next spring.

The metal schedule incorporated in the Underwood measure provided for a tax of 6 per cent. on pig iron; 10 per cent. on alloys and from 15 to 35 per cent. ad valorem on various kinds of manufactured and partially manufactured metals. These rates represent a downward revision of from 2 to 25 per cent.

The free list under the Underwood bill includes iron ore, hoop and band iron, barbed wire, fence wire, cut and wrought nails, tungsten ores, and a few other items.

Bankers Offer Overland Stock Purchase

Advance offering of the recently purchased block of $5,000,000 first preferred stock of the Willys-Overland Company has been made by William Salomon & Company. The stock bears 7 per cent. cumulative dividends. On the basis of last year's report of consolidated earnings, the company earned 66 per cent. on the preferred issue. According to the Salomon announcement, the company sold 22,548 cars in 1911-1912 season and for the year ending June 30, 1913, expects to put out 38,200. Figuring on that basis the bankers state that the company should earn full par value on the preferred issue offered.

DETROIT, MICH., Nov. 25—The first real get-together meeting of the Detroit Section of the Society of Automobile Engineers was staged at the Detroit Motor Boat Club house on Thursday evening, November 21. An informal dinner was served and there were 125 on hand to enjoy the repast. This is the largest gathering which has ever turned out for an affair of any nature given by the Detroit section. No engineering subjects were discussed, the object being to afford the members an opportunity to become better acquainted with one another. By offering social advantages to its members in addition to those merely technical it is hoped to gather in many others.

Grand Prix To Be Revived

French Club Decides to Run Classic Next Year With Small Field if Necessary But Extends Time

New York Dealers Organize To Rehabilitate Contests and Seek to Secure the 1913 Vanderbilt Cup Race

PARIS, Nov. 15—After being buried, the French Grand Prix race has been revived, the Automobile Club of France deciding to hold the race whatever the number of starters and to admit entries at ordinary fees until December 31, and at double fees until March 31. The race will be held during the first fortnight in July; the place has not yet been selected. At the present time there are seventeen entries, the makes being Sunbeam, Delage, Peugeot, Schneider, Itala (with valveless model) Mathis, Mercedes, and Opel.

In an interview, Chevalier Rene de Knyff, president of the sporting committee of the Automobile Club of France, gave it as his opinion that with the extended time for receiving entries the total number would be thirty-five or probably forty starters, thus assuring a most interesting race.

It was recognized that the original decision to close the lists at the end of October was a mistake, for a number of concerns were unable to decide whether they would be able to compete at such an early date, and even those who had entered were unable to commence the construction of cars until they had received assurance that the race would really be held.

A sidelight on the reasons which led the Automobile Club to revive its Grand Prix, after having obtained only sixteen out of the necessary forty entries, is given by *L'Echo des Sports.* "The real reason why the Automobile Club of France has decided to preserve its Grand Prix is the attitude of the newspaper *L'Auto*. Once more our contemporary has earned the hearty thanks of the automobile industry. Without it the Grand Prix would certainly have been dead and buried. It must not be supposed that this is a joke; it may be a little ironical, but that is all. We can declare to-day, without fear of contradiction, that *L'Auto* was not expecting the results it has provoked. All that it hoped for was the burial of the Grand Prix, although it took care not to give public expression to that hope. It would have followed the funeral procession with tears and lamentations; it would have accompanied the defunct as far as the cemetery. Then, having taken off its black coat, it would have rolled up its sleeves and given itself up heart and soul to the triumph of its own race, that race which was announced in all the majesty of big headlines and leaded matter in the issue of the paper declaring the certain abandonment of the Grand Prix, dead with only sixteen out of the necessary forty entries. It was a note of defiance which awoke the club to action. Without this note the automobile club would have been content to allow its Grand Prix to sleep its eternal sleep. Instead, it rushed into the fray, taking a decision which has earned for it the compliments of all lovers of sport."

The 3-litre race, to be held by *L'Auto,* has been fixed for Sunday, June 29, the course not yet being decided on. Present entries are Peugeot and Delage, but the list does not close until March, and it is confidently expected that between thirty and forty cars will be secured.

New York Dealers Seek Vanderbilt

The Motor Dealers' Contest Association, of New York, composed of prominent members of the metropolitan trade, was formed Monday at a meeting attended by about forty. The purpose of the organization is to rehabilitate racing, road contests and tours and the main object that confronts it is the capture of the 1913 Vanderbilt Cup race. The tentative plans of the association are to secure the race and run it on Long Island.

The association will be incorporated for $30,000 and the shares will be sold among the trade, the individual concerns of which are limited to three shares each. The machinery of the organization will consist of a board of directors, numbering eleven; an executive committee consisting of eight and three committees; respectively on racing, road contests and touring to be named by the board.

Temporary Chairman John C. Wetmore has announced the following committee to canvass the trade for co-operative support: George H. Robertson, William C. Poertner, Edward McShane, E. Lescaris, J. C. Nicholls, A. J. Inderrieden and E. F. Korbel.

Contest Board Rules on Protests

At the last meeting of the Contest Board A. A. A. the appeal of the Central Auto Company, of Grand Rapids, Mich., from the referee's decision in the recent reliability run of the Grand Rapids Automobile Club, penalizing a Cadillac car two points for raising the hood in control, was overruled. The hood was raised by an outsider but the board ruled that the possibility of such an occurrence showed negligence on the part of appellant.

The Coey-Mitchel Auto Company and the Stutz Motor Car Company, of Chicago, were suspended until June 1, 1913, for failure to report for start in the recent run around Lake Michigan.

The Moline Automobile Company and the Staver Carriage Company were suspended until June 1 for advertising the performances of the Moline and Staver-Chicago cars in the Lake Michigan run as those of stock cars.

Hoosiers Endorse Coast Tour

INDIANAPOLIS, IND., Nov. 25—The Indiana Automobile Manufacturers' Association, at a meeting in the Claypool Hotel in this city last Thursday night, gave a plan for a run from Indianapolis to the Pacific Coast its unqualified indorsement. This means that the Indiana manufacturers will make the trip, and July 4 was selected tentatively as the date for making the start from Indianapolis.

This trip will take the place of the Indiana Four States Tour which was held this year and last. It is estimated that a car with two occupants can make the trip for $370, including the return trip by rail. The route has not been selected and a committee is now working out this feature of the run.

H. O. Smith, of the Premier Motor Manufacturing Company, has suggested that immediately following the arrival at the Pacific Coast, exhibits of Indiana-made cars be held in Los Angeles, San Francisco, Portland and Seattle.

Motor Truck Club Extends Scope

The Motor Truck Club, of New York, has elected Ellis S. Howland secretary and general manager and has secured official headquarters at 1845 Broadway. The club intends to maintain a bureau for the collection and distribution of data on automobile trucks. It will hold weekly sessions at which leading men in the industry will be invited to speak.

The welfare committee, consisting of L. A. Van Patten, Emerson Brooks, E. W. Curtis, Jr., and Arthur J. Slade, has outlined some of the new activities in its recent report. Among the recommendations are the following: That a bureau of information be established to secure specific information about costs; that a registry of motor truck drivers be established; that the committee on papers work out programs for the coming year so that special emphasis can be laid successively upon the various phases of truck operation and numerous other practical suggestions.

Market for Motor Trucks Outlined By Industries

OF much interest to the industry is the following article and compilation issued by the commercial vehicle committee of the National Association of Automobile Manufacturers on the market for trucks as shown by the interest displayed by the various commercial industries in the last national shows.

A tabulation of all responses received to invitations to attend last winter's shows has been made by the statistical department of the National Association of Automobile Manufacturers. Invitations were sent, in round numbers, to 40,000 companies located in the territory embraced by the New England, Middle Atlantic and North Central states as far south as Tennessee and as far west as Oklahoma. Most of these companies have a financial rating of $50,000 or more, indicating that they are easily capable of buying trucks or delivery wagons.

About 7,500 companies responded to the invitations, and these are included in the tabulation, making the most comprehensive investigation ever undertaken along this line.

As originally compiled, the list showed 225 distinct lines of business, including manufacturers, jobbers, wholesalers, retailers, commission merchants and others in each line. These various trades have been rearranged into broad groups of allied lines for convenient reference. In order of the number of replies received, the trades most prominently represented are as follows:

Building and contracting trades	482
Metal and hardware trades	392
Grocery trades	306
Machinery and tool trades	276
Light, heat and power companies	255
Dry goods and clothing trades	253
Furniture, beds and bedding, carpets, rugs and house furnishing	223
Brewing and liquor trade	219
Expressing, teaming, etc.	214
Coal and wood	205
Printing, publishing and allied trades	176
City governments	155
Lumber trades	151
Textiles and dyeing	143
Paints, oil and decorating trades	142
Heating, plumbing and steam fitting trades	126
Department stores	123
Storage and moving	117
Produce and commission	117
Steam railroads and equipment	112
Paper and paper box trades	111
Meat and packing trades	106
Boots, shoes, hats, gloves and men's furnishing	100

It should be borne in mind that the number of companies represented in any particular trade is not necessarily an indication of the exact relative interest of that trade in commercial motor vehicles nor of its probable absorbing ability during the coming year. These are dependent upon the proportion borne by the number represented in the list to the total number of companies in each trade in the territory tributary to the shows and the average number of trucks operated by the truck owning companies in that trade. For example, the probable demand for power vehicles by the 123 department stores would greatly exceed the demand by the 176 printing and publishing companies or the 117 storage and moving companies.

In the entire United States there are 4,700 department stores, of which 123, or about 1 in 38, are represented in the show list; there are 989 storage warehouses in the country, of which 78, or 1 in 12, responded to show invitations; and there are 26,500 printers and publishers, of whom 133, or 1 in 200, responded

The tabulation is appended, with the trades insignificantly represented omitted.

Trades Represented at National Motor Truck Shows

	Chicago Show	N. Y. Show	Both
Baking and bakers' supplies	19	31	50

Machine Tools Interest Industry

rle L. Downs, secretary of the Automobile Board of Trade Committee, has returned to New York after a trip through Middle West devoted to the project of holding an exhibit of ine tools in connection with the coming national show in York. Mr. Downs stated that not over six manufacturers een signed up for the show but that there are prospects for siderable representation despite the shortness of the time s still available.

: show situation is somewhat complex as regards machine The contemplated exhibit will be the first to be held in ountry and its announcement attracted a large amount of ion throughout the industry. At the Olympia show there uch an exhibit and it proved to be one of the most inter- features of the show. But the manufacture of machine is largely on order, little stock being maintained. Thus, ifficulty that stands in the way of a complete exhibit in ry is that available machines will be hard to get.

er F. Clarkson, general manager of the Society of Auto- : Engineers, declares that a complete exhibition of ma- tools would be interesting to the whole industry and that A. E. was strongly in favor of adding such an attraction national show.

Atlanta Show Makes Much Money

ATLANTA, GA., Nov. 25—The Atlanta automobile show ended Saturday night. The accounts have not been cast yet, but it appears that enough money will be in the treasury to pay all expenses, refund to each exhibitor half the money he spent for space and will still leave $2,500 for a working fund.

The show was more economically run this year than last, but, thanks to good weather, to prosperity in the South, to the fine display of cars and to much publicity, and because it was given right at the start of the Southern buying season, it drew immeasurably larger crowds than ever before.

Senators To Hold Automobile Show

WASHINGTON, Nov. 25—Washington is to have an automobile show early in the new year which promises to eclipse any ever given in the national capital. T. Oliver Probey, president of the Michigan Motor Company, and proprietor of the Probey Carriage Company, will be the executive chairman of the show.

Committees will be appointed within the next 2 weeks to aid Mr. Probey in his work. The dates for the show have been decided upon. It will begin February 3, and last 1 week. The show will be given in Convention Hall. It has been 2 years since Washington had an automobile show.

To Oust Unhandy Manograph German Savant Builds Mechanical Indicator So Small and Rigid as to Shake with Motor but Never Alone—The Diminutive Diagrams Enlarged at Leisure—A Popular Pyroscope—Carbureter Construction

INDICATOR for High-Speed Motors—When the customary indicators are used for registering pressures and piston speeds in automobile engines the results are not satisfactory, and this accounts for the fact that these instruments are rarely used by automobile manufacturers, though they are found indispensable in the development of new designs or modifications of larger and slower motors. In recording pressures, the masses of the movable parts of the instrument—the pistons and the writing stylus—are subject to disturbing independent vibrations in the higher degree the larger and the more rapid the variations in pressure are in the machine under test. The shorter the duration of these independent vibrations, which are due to the intrinsic mechanical properties of the measuring instrument, can be made, the more accurately the true course of the variations of pressure can be recorded. To attain accuracy, the movable masses and their movements must both be reduced to a minimum. On this principle the change was made from the simple Watt indicator to the short-stroke instrument with a mechanically magnified movement for the stylus and finally to the optical indicators or manographs which work with exceedingly small masses. But with the latter it is necessary to use photographic registrations, and this feature renders them less practicable, as it is difficult to obtain sharp lines of even thickness, while the photographic plate is also underexposed when the light moves rapidly and overexposed when it moves slowly. Moreover, the whole process is laborious and does not admit of taking diagrams in rapid succession.

In applying the customary instruments to the recording of piston speeds, it has been considered most important to have a mechanism which could be attached quickly to the motor—as by belt drive—and one which was kinematically correct in principle, and less attention has been paid to the need of having it able to cope with the accelerations arising in its use at high motor speeds. Not only the drive must not break but it must also transmit the movements without gross errors. In order to meet this requirement the drive must be rigid.

Basing his efforts on these ideas Dr.-Engineer O. Mader, of Aachen, has aimed to build a new kind of indicator, which he terms the Mikro-Indicator, and the manufacture of it has been undertaken by Stärzl Brothers, 18 Kapuziner strasse, Munich. This instrument is supposed to be sufficiently accurate at motor speeds up to 2,000 revolutions per minute; to admit of taking diagrams in rapid succession; to produce diagrams which are visible at once, permanent and susceptible of manifolding; to be easily operated and not to be sensitive to rough handling. Different views of the construction are shown in Figs. 1, 2 and 3, while a diagram of the registering method is shown on a larger scale in Fig. 4. It is similar to the early indicators in this that the diagram is drawn direct from the movements of the indicator piston, and in this case by means of a sharp steel point which traces the curve on smoked glass, but the stroke of the indicator piston is reduced to a maximum of 2 millimeters, and the magnifying of the very small diagram thus produced is done subsequently under a microscope, thereby circumventing the disturbing influence of the motor move-vibrations on the magnifying process.

The drawing of the motor piston stroke is effected by a lateral movement of the light stylus. The indicator piston has a flat top A, Fig. 4, on which the circular disk forming the end portion of a small lever B may slide. The stylus S extends from the center of the disk. The other end E of lever B is drawn to and fro by the oscillation of a crankarm C on spindle D. A fine spring F holds B down to steady contact with A and obviates lost motion in the joints.

The indicator piston is guided below by the cylinder wall G, Fig. 2, and above by securing the hollow piston rod to the double, oppositely-wound spring H. These three parts—piston, piston rod and spring—form a unit and must be replaced as such, if it is desired to change the dimensions of the diagrams. The area of the piston is normally 1 square centimeter for pressures up to 30 atmospheres and proportionately smaller for higher pressures.

The stopcock J and a water-cooling chamber are built into the body of the indicator cylinder, the provision for cooling being needed only when the cooling system of the motor is inefficient at the point where the indicator is screwed in. By this compact design the tubular connection with the interior of the motor is made short and unobstructed, and the bore of it represents an addition of only 3 cubic centimeters to the volume of the motor under test.

The diagram-plate-carrier is a U-shaped frame pivoted upon a fixed shaft K and pressed by a spring L against a round eccentric cam M. Into this frame the smoked glass plate is inserted from above together with a backing plate, and both are held by leaf springs in any position given them. With one quick turn of the cam, by means of a crank, the glass plate is pressed lightly against the stylus and is again immediately drawn back.

If another diagram is to be taken, the plate is raised by turning the knob O. In this manner 24 diagrams can be taken on one plate in two rows, in 30 seconds if necessary. To start the second row, the plate is pushed to one side on the shaft K. The glass is a 28 by 48 millimeter plate, as commonly sold in the open market for microscopic preparations and germ cultures.

A simple drive with few joints is preferably used for actuating the micro-indicator; for example a walking-beam drive as indicated in Fig. 5. In this matter it is of the greatest importance that the bearings of the drive, as well as the indicator, follow all the vibrations of the motor. While the walking-beam drive is not kinematically uniform, the errors arising from this fact, and especially from the limited length of the beam, may be obviated largely by shortening the ecentric arm. In using this drive, it is advisable always to use the same crankarm length (45 millimeters), whereby the variations of the radius of the eccentric may be held within narrow limits (from 13 to 15 millimeters). The only parts which must be provided especially for each kind of motor is the driving crank, or eccentric, and the middle portions of the beam, for which parts, therefore, very simple forms have been chosen.

So as to be able to stop the movement of the writing lever—to replace a dulled stylus, for example—a coupling is provided for this lever which has no lost motion and which, it has been found, may be easily secured or released by hand even at the highest motor speeds.

The adjustment of the drive must be made with the greatest care, to avoid large errors in the diagrams. At a certain position of the piston—selected at the middle of its stroke and not at the dead center—the stylus must mark the same spot when going to the left as when going to the right.

THE ENLARGEMENT OF THE MINUTE DIAGRAMS

An ordinary microscope magnifying 40 times is used for obtaining an enlarged view of the diagrams. Mere observation of the diagram in the microscope is sufficient for guidance in the adjustment of valve cams and ignition. To permit the measuring of diagrams, however, they must be enlarged either by means of an ordinary enlarging-camera or by drawing an enlargement by hand with the aid of a special device furnished with the microscope. The latter is operated at an angle of 45 degrees, and the device consists in an arrangement of small reflectors in the under-part of the sight tube, near the ocular, by which the image of a blank drawing-surface—which is located directly beneath the ocular and conveniently to the operator's hand—is thrown into the plane of the enlarged image of the diagram, so that the operator sees both at the same time. This enables him to follow the lines of the enlarged image with a pen on the actual drawing-surface.

To define the scale of enlargement which has been used in representing the motor movements and pressures in the diagram, both the magnification and the resistance of the indicator spring are to be considered. The magnification is verified by a scale traced on glass, and it remains constant. The spring action is determined by a convenient pressure gauge operated with weights, as represented in Fig. 6.

The principal use for the micro-indicator lies in its handiness for determining the mean effective pressure and separating the thermic from the mechanical elements in the efficiency of a motor. The author refers to a number of determinations of this nature which he has made with the instrument of his design and by which its superiority in accuracy over old-style mechanical indicators is borne out. Its superiority over the manograph lies mainly in its convenience, robustness and the sharp and permanent lines of the diagram.

Among other uses, there may be mentioned the adjustment of valve cams and ignition, the determination of the time required for ignition and flame propagation, the measuring of compression and of possible leaks, estimates of strangulation in intake and exhaust pipes and valve ports, as well as of the nature of the combustion and the quality of the carbureter.—From excerpt in *Der Motorwagen* of September 30 of article first appearing in *Dingler's Polytechnisches Journal.*

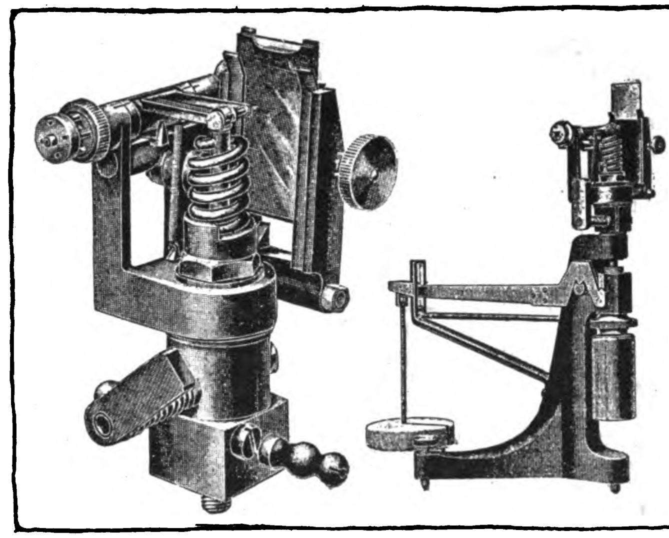

Fig. 1—Mader micro-indicator. Fig. 6—Spring pressure gauge

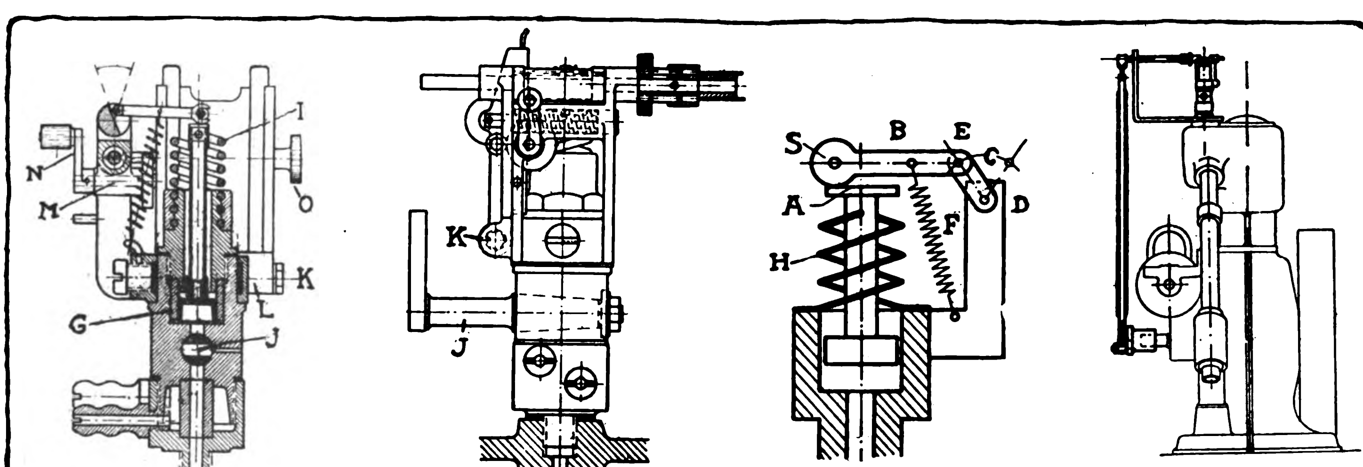
POPULAR Pyroscope—Among instruments which compete for ordinary industrial purposes with the scientific optical pyrometers, as well as with the electric instruments, one of interesting simplicity is mentioned as in use in some German factories. In general appearance it may be described as a kerosene lamp with a metallic and enlarged chimney to the side of which a short telescope is attached. The rays from the kerosene flame pass horizontally through a multiple diaphragm composed of a number of transparent films which are colored differently, so that the diaphragm as a whole presents a scale of colorations which in combination with the light from the kerosene flame correspond to the heat colors of steel from 650 deg. to 1650 deg. C. Obliquely in the telescope tube there is placed a small mirror which reflects the rays from the lamp, transmitted through one of the films, to the eye of the observer and makes this image appear as a round spot on the light image of the heated piece of work which is seen direct through the telescope. By turning a knurled disk the diaphragm is turned around until the particular film is in line which gives a light that disappears on the image of the work, for lack of contrast, and a hand is at the same time moved around on a



Figs. 2 and 3—Different views, partly in section, of Mader micro-indicator. Fig. 4—Diagram of the recording mechanism. Fig. 5—Mounting and walking-beam drive of Mader instrument drum inscribed with a scale of temperatures. The moment the correct position is found the temperature of the work can thus be read offhand. The accuracy depends upon the division of the scale, but also upon the constancy and light of the kerosene flame. Considerable attention must be given to the cleaning of the lamp burner and the regulation of the flame. The latter should have a certain height, for example 18 millimeters.—From *Der Praktische Maschinen-Konstrukteur*, September 19.

LATEST G & A Carbureter—Most of the design features in a new model of the Grouvelle & Arquembourg carbureter may be discerned by a glance at the accompanying illustration, Fig. 7. The large jet G is oblique, which arrangement facilitates adjustment and inspection and especially the adaptation of the same carbureter model to different motor sizes and motor designs, by modifying the holes at G. The additional air intake operates automatically by means of metal balls resting over the air holes, which means that the mixture is determined not only by the position of the throttle but also by the motor speed, and mainly by the latter. The throttle is closed completely when the lever M is in position 1, so that no gasoline is used when the vehicle is running downhill by gravity. In positions 2, 3 and 4 of lever M, the suction is switched by way of the groove *k* in the throttle body into channels *a* and F, drawing air from around the small jet *g* and gasoline from the latter. In position 4 the large jet also begins to act. The small tubular jet *g* passes through the middle of the float and acts as the stem for the needle valve. Two holes *r*, near the bottom of the float chamber, admit the gasoline to its interior. A hot-water chamber R, connected with the cooling-water system, assists in evaporating the spray from this jet.

The working parts of this carbureter are easily taken apart and reassembled without the use of tools. The wing nut L gives complete access to the main jet. By pressing down on the yoke N, against spring J, the tube F is released, and then, by the extension of the spring, the pin H is released also, permitting the yoke N to be turned around the housing of the priming-rod P. Now the cover of the float chamber comes off, and the jet *g* with the weights C and the float can be removed if desired. Also, with the cover removed, the action of the needle valve may be regulated, the weights being secured to the jet tube and not to the cover.—From *Omnia*, November 2.

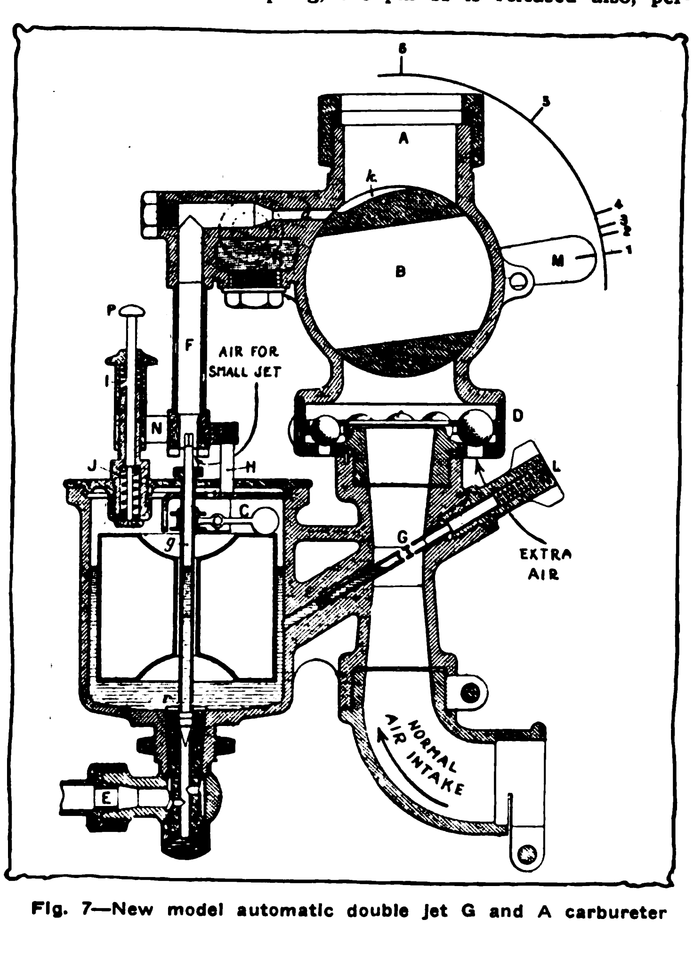


Fig. 7—New model automatic double jet G and A carbureter

MACHINES to Test Skill—As a consequence of the worldwide movement started by Frederick W. Taylor for increasing the efficiency of traditional working processes through analysis of the movements composing them, Professor Imbert, of the University of Montpelier, has devised a number of ingenious devices by which various kinds of common work may be measured with a view to determining what wages each of the working operations ought to command, and the French government has thereafter subsidized further experiments in the same line. Similar small machines have been made by which, for example, the skill of a workman who applies for a job may be put to a decisive and impartial test. In the case of filing or the cutting of metal sheets these devices furnish diagrams of the work done by each hand, of the vertical movements as well as of the horizontal ones and of the pressure exerted at any point of the stroke of the file or the shears, and by comparing the diagrams produced by a skilled workman with those produced by one whose skill is less well known the value of the latter as a workman can be gauged without the need of watching him. The speed is also recorded.—From illustrated article in *Werkstattstechnik*, October 15.

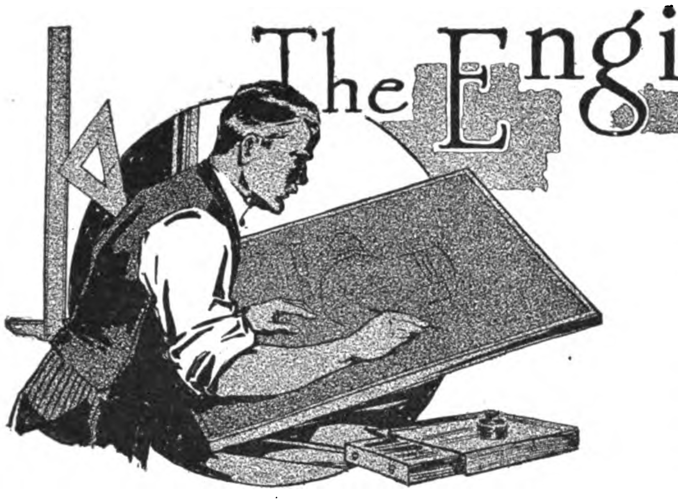
ALTERNATING Shows in Paris—The Association of French Automobile Manufacturers (*Chambre Syndicale de l'Automobile*) under the leadership of Marquis de Dion, has resolved that it is desirable to hold an automobile salon in Paris every year but that it is equally desirable that constructors in each main branch of automobile manufacture should not be called upon to develop and exhibit important improvements oftener than every two years, and that, therefore, one of two successive annual shows should comprise pleasure automobiles, vehicle bodies, bicycles, motorcycles and accessories, and that the other should be limited to commercial motor vehicles, motor boats and machine tools. If, however, the makers of accessories should express a preference for participating in both shows, the opportunity should be held open for them. The proposition is meeting with general approval though some dissenting voices are heard.—From *L'Auto*, November 7.

INTERNATIONAL Influences—At the Olympia automobile show there was seen on the stand for Charron cars one of these fashionable French vehicles equipped with a Lentz hydraulic transmission. The latter, according to *L'Auto*, of November 13, was considerably improved as compared with the form in which it first made its bow to the public. Though a German construction it was received with favor in England and by this route seems now to be in a fair way to win French approval. It was described in THE AUTOMOBILE of May 30.

GRAND Prix for 1913—The Automobile Club of France decided at a meeting held November 6 that a *grand prix* race shall be held in France in 1913, whether the number of entries received before December 31, 1912, comes up to the expectations or not. The decision was taken in order to justify manufacturers in making their preparations for the event well ahead of time.—From *L'Auto*, November 7.

SPLASH Guards—The second public competition for splash guards in Paris has been held, but the press refuses to take the new accessory seriously. It is not too much to ask that streets should be kept so clean as to render splash guard unnecessary, comments *Omnia*.

The Engineers' Forum



3-Point vs. 4-Point

Discussion of Relative Merits of These Systems for Supporting the Motor and Gearbox

Van Dervoort Lays Stress on Alignment—Birdsall Finds Both Systems Satisfactory

Part III

W. H. Van Dervoort Prefers Three-Point Suspension

Edward T. Birdsall Finds That Both Types Have Advantages

EAST MOLINE, ILL.—Editor THE AUTOMOBILE:—We started in at accomplishing what we now get in our three-point motor suspension—the alignment of transmission and motor by preventing the distortion of the frame as much as possible, through the use of the three-point spring suspension. We were among the first of the American manufacturers to adopt the unit power plant and with the adoption of this unit power plant we discarded our three-point spring suspension and went to the three-point power plant suspension, as in the unit power plant it is absolutely necessary to maintain perfect alignment of the motor and transmission shafts, and inasmuch as as it is not practical in the light-weight construction of automobile power plants to make the parts sufficiently rigid to withstand the severe cramping due to operating a car over unequal surfaces, the necessity for overcoming these strains as much as possible by the use of the three-point suspension for the entire power plant is apparent.

I feel there are some advantages to the four-point motor suspension when used in connection with an independent transmission, where perfect alignment between transmission and motor is not imperative.

In our earlier construction we used two points of suspension at the front end of the motor with a single point at the rear end of the transmission. Our present construction gives the single point of suspension at the front end of the power plant and the double point of suspension at the front end of the transmission, allowing the transmission to overhand the rear supports. This makes possible a very considerable reduction in the weight of the connecting link between engine and transmission, and inasmuch as we advocate an open flywheel housing instead of a closed flywheel housing, this is a point of considerable importance to us.—W. H. VAN DERVOORT, Moline Automobile Company.

DETROIT, MICH.—Editor THE AUTOMOBILE:—As to the relative merits of three- and four-point suspension I believe that three-point suspension is more necessary where a main frame construction is used than in the case of a subframe design. I rather favor the three-point for both pleasure and commercial cars, although I have yet to experience any trouble with the four-point, providing the strains are properly taken care of.

On commercial cars I would use the three-point suspension on account of the added assurance of freedom from possible trouble due to the gross misuse that the average truck gets from careless or ignorant drivers.

Then, again, there is the selling department's talking points to be considered, which often have a serious influence on design.

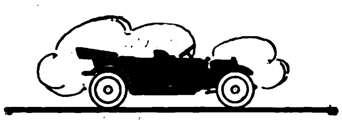
At the present time I have three pleasure cars and two trucks on the boards and they are all of main frame three-point construction.—EDWARD T. BIRDSALL, Consulting Engineer.

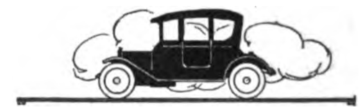
MARTIAN HEIGHTS, N. Y.—Editor THE AUTOMOBILE:—By triangulated trussing, stresses are transferred from joints to the material of struts and stringers, roughly speaking, but this undoubted virtue of the triangle wherever joints are most likely to constitute the weak points is not utilized much in automobile construction. The corner gussets of the frame are placed as disadvantageously as possible, for example. In my opinion 3-point suspension has no value apart from the construction together with which it is used. It may be advisable with one, inadvisable with another. If it were true that a 3-point cradle supporting the motor would conform to any position into which those three points in the automobile frame at which it is supported may be forced, a certain advantage relating to the protection of the motor would be realized, but, even when double-swiveled at one of the points, it does not do so. In the case of whipping or bending of the frame the mutual relations of the three points are changed, and the cradle is cramped to resist this deformation. It is only in the case of symmetrical torsion of the frame that the cradle hung at three points is relieved of stresses in higher degree than one hung at four points. The cradle must, then, after all be made strong enough to resist and prevent certain deformations of the frame, or else the suspension at the most exposed point, and possibly at two of them, must be made flexible in all three dimensions. On the other hand, a four-point cradle can more readily be made rigid against whipping and pitching stresses and can also be flexibly supported, with sufficient yield to allow for torsion, provided the frame construction and the spring suspension of the vehicle are designed with a proper degree of rigidity, considering the other purposes which they have to serve—for example that of carrying a vehicle body with doors and windows which should fit and operate flawlessly.

If it may be assumed that the art of automobile building has advanced to a point where it cannot be accepted as satisfactory engineering to protect the motor at the cost of neglecting other important requirements, it seems hard to find even an excuse for hanging the biggest weight in the whole construction at the smallest possible number of points. It stands to reason that, so suspended, it may contribute to the aggravating of frame deformation rather than to the checking of it, notably in all cases where the suspended unit rocks freely without being subjected to internal stress.

The subject is, however, much too large to be covered convincingly in a few lines.—UNATTACHED S. A. E. MEMBER.

Hansom Type Coupé for E.M.F. Chassis





Compactness and General Design Are Especially Suitable for a Runabout Chassis

By George G. Mercer

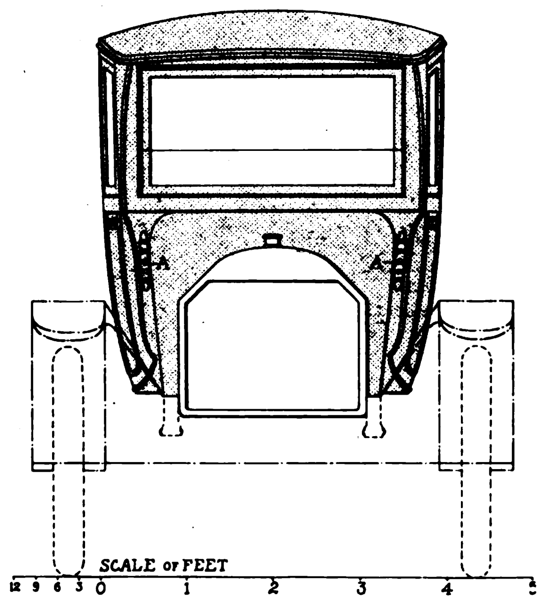


Fig. 1—Front view of E.M.F. coupé design

THE accompanying scale drawings show a light-weight coupé body adapted from the lines of the well-known horse-drawn hansom cab, and suitable for service on a small runabout chassis. Such a body design would adapt well to the chassis of the E.M.F. 30 roadster, and this car has therefore been chosen as a basis of illustration.

The hansom cab is probably the most compact two-passenger vehicle that has ever been generally used, and its general design is for this reason especially suitable for application to a small chassis where light weight is an important consideration.

The E.M.F. 30 has a wheelbase of 112 inches, with a 4 by 4.5-inch motor and tires of 32 by 3.5 inches. This car is regularly equipped with three or more styles of bodies. The illustrations show the roadster model with the body removed and the proposed coupé body set in its place. The gasoline tank, tool box and tire carriers remain at the rear undisturbed, and the wheel guards are also untouched.

In its standard form the E.M.F. runabout is arranged for right-side driving, and owing to the fact that the change gear and brake levers are set well within the frame for operation on the inside of the foredoor, no changes are necessary and therefore no expense is incurred in order to prepare the chassis for the reception of the new coupé body.

Fig. 4 gives a good general impression of the body mounted. It may be of interest to point out that in actual dimensions the body is smaller than appears at first sight, this effect being produced by a full extension of the roof at the front, and also by carrying the forward moulding at the bottom well in advance of the door. Constructed as shown, this body should not exceed the weight of the stock roadster body by more than 450 pounds.

All the most important measurements are indicated in the drawings. As shown in Fig. 4, the width of door over mouldings is 20 inches while the extreme length of the body from front to back on the belt line is only 39 inches. The distance from the dash to the front of the seat cushion is the same as on the roadster, as also is the height from the floor to the top of the cushion. The vertical distance between the cushions and the underside of the roof is 39 inches, and the width of the cushion, shown on the plan, Fig. 2, is 37 inches. The space between the steering wheel and the seat back is approximately 15 inches. These interior measurements afford ample accommodation for two average people.

The exterior dimensions of the body are: length 50.5 inches by 47 inches wide. The construction is combination wood and metal panels with wood framing, the lower body and door panels and the cowl being formed of metal. Steel can be used to advantage for all these panels except the cowl, though by so doing the weight of the body would be slightly greater than with all aluminum panels. The upper body panels, side and rear are .375-inch thick whitewood, and the roof panel is either pine sheathing or laminated wood roofing. The rounded corner at the rear is formed with the framing pillar, and the side and back panels, both upper and lower, do not follow around the corner and intersect, but terminate at the moulding line indicated on the two views Figs. 3 and 4.

As indicated by dotted lines in Fig. 4, the location of the levers permits of easy entrance from either side. The space on

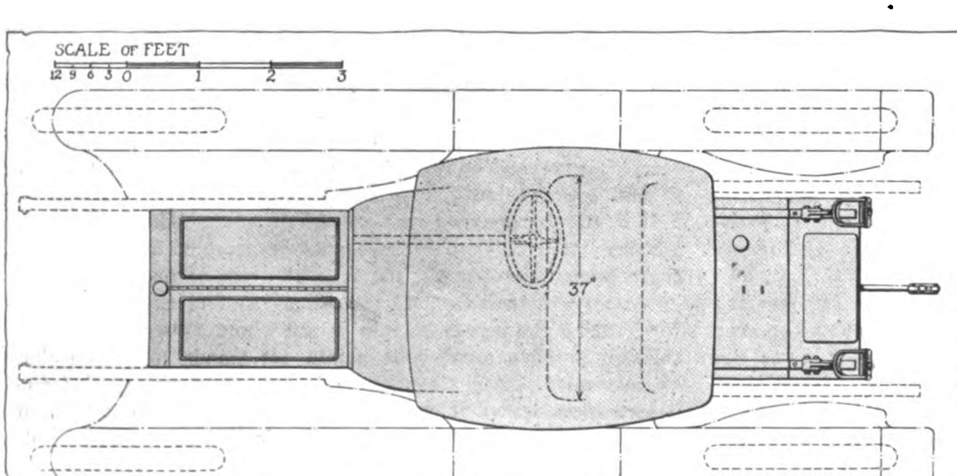

Fig. 2—Plan view of suggested E.M.F. hansom type coupé

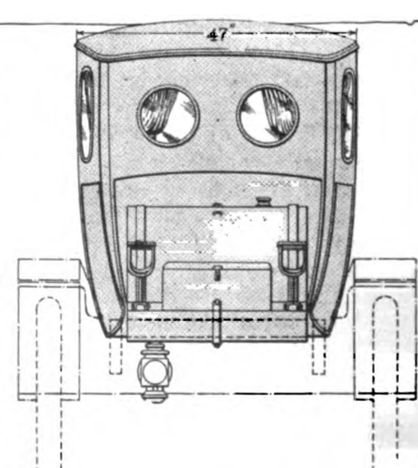

Fig. 3—Rear view of E.M.F. coupé

the chassis occupied by the body extends from the dash to the block that supports the tank at the rear without disturbing the latter. Regarding the dash, the best plan is to have this made integral with the body. It costs a little more for a new dash and installing it on the car, but it effectively prevents the rain leakage around the joint of the moulding, that is apt to occur if the dash is not built solid with the cowl.

Plate glass windows with mahogany wood frames, are fitted to the doors, provision being made for opening by dropping their full length. The oval lights on the sides and the round ones at the rear are made stationary and metal tee mouldings are used around the openings to keep the glass in position and to serve as a finish.

Ventilation is secured by dropping the door windows, or opening the front windshield visor which is indicated in Fig. 4. In addition there are two elongated openings, marked A on Figs. 1 and 4, that are controlled by shutters operated from the inside of the car.

The lamps used are those furnished with the stock car, the only ones disturbed in mounting the new body being the dash lamps, and these are reassembled on the car in their former positions. The horn is located under the engine hood and does not call for any interference.

For the exterior finish different shades of green combined with either yellow, or white or black are good suggestions, and some of the brown shades combined with black are also very suitable. Interior trimmings chosen to match whichever of these combinations is adopted will look and wear well.

The most economical color to use, however, will be the standard color on the stock car, as this well save repainting the chassis to match, provided the paint is in good condition. Assuming that this latter decision is made, the lower body panels and the cowl will be blue, as will also the recessed panel that forms the rounded corner at the rear. This will be blue the entire length from top to bottom and between the mouldings that mark the end of the side and back panels. The mouldings will be black and also the roof and the upper panels above the belt. Black should also be used for the underside of the roof where it projects forward of the windshield.

The exterior color scheme is therefore the same as the stock body, blue with black, hair line gray striping and gray wheels.

If a cloth is decided on for the interior finish a gray to match the color of the wheels and the striping could be introduced with pleasing effect. Cloth is certainly better for trimming the interior of a winter car body than leather, all things being equal. There is a coziness and warmth to cloth that no leather can give.

The most durable cloth materials in the lighter shades are the cords, either whipcord or the bedford cord and the latter seems to be most generally favored. Among the gray bedford cords it is common practice to use a fleck or marking of some darker shade, and a gray with a black fleck will suit admirably for trimming the seat, the sides and back of the seat, the body and roof. The broad lace used on the doors, and the finishing lace would of course be chosen to match the interior scheme of color, as also should the floor carpet. Suitable curtain material would be plain gray silk, the doors being mounted on spring rollers while those on the side and back windows could be draped and held in place with a cord.

The appointments will consist of silver mounted electric dome light in the roof, gray morocco covered toilet and card cases, and ash tray for the doors and pockets on each side under the cowl. All metal parts inside silver finished.

Though of compact form the inside dimensions of the body permit of ample thickness in the trimming of the seat back and sides and cushion. For the latter 6 inches is allowed for the depth. A driving cushion does not need to be made too thick. An excess of flexibility in the seat cushion used by the driver, due to the greater length of the cushion springs and consequently greater thickness of the cushion, is undesirable because it gives a rolling motion to the seat. The cushion should therefore be moderately firm and the trimming of the seat back should not be too far removed from the steering wheel. Both the seat back and the cushion should support the driver's body firmly in the position that he is obliged to assume in order to handle the wheel properly. The trimming of the passenger seat can be made more luxurious to suit a more reclining position.

The cost of a body according to the design and specifications above outlined will approximate an outlay of $900. This should insure first-class workmanship and materials and should be of a style and finish to satisfy any reasonably critical customer. This figure includes mounting the body on the chassis ready for service.

On the return of warm weather the old body can be replaced with little trouble, the only expense being that of the actual labor of making the change. By providing himself with this extra body the owner of a small runabout is therefore prepared for comfortable traveling all the year round.

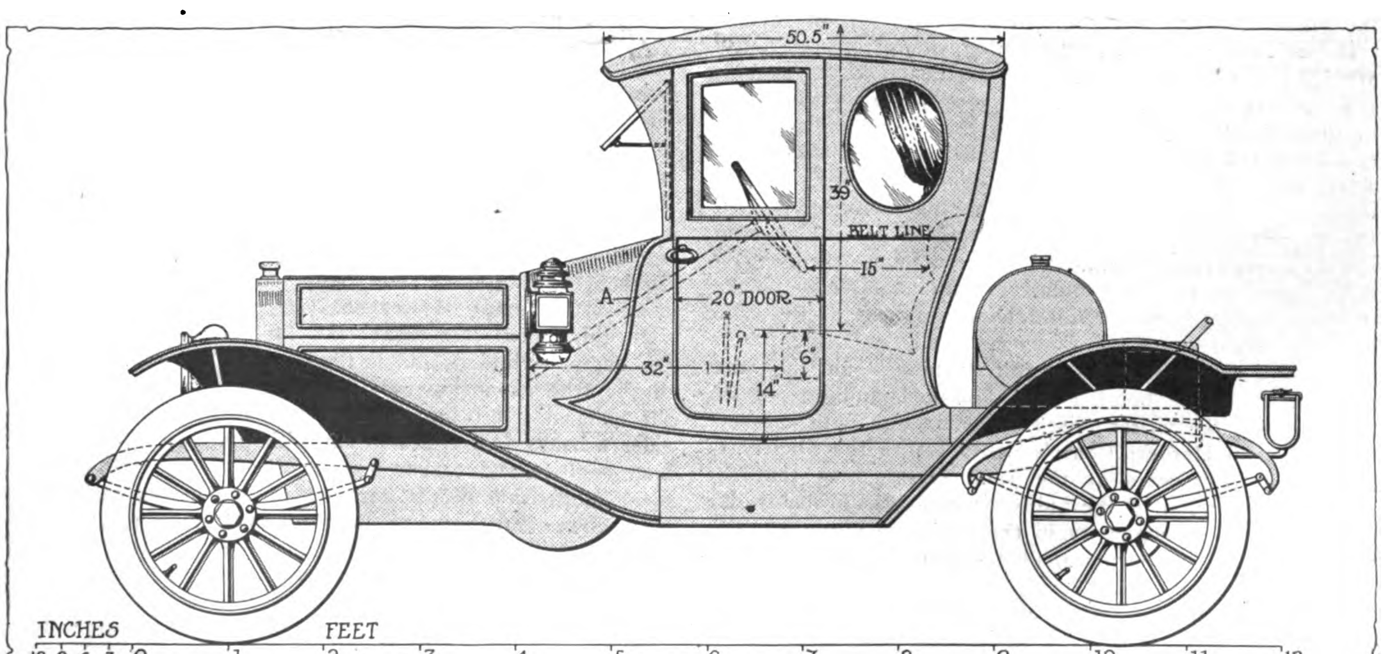

Fig. 4—Side elevation of the hansom type coupé design for E.M.F. 30 roadster chassis

Carburetion

Part II

by Robert W. A. Brewer

Subject Digest

Carburetion cannot be good unless the liquid fuel be divided into the most minute particles.

When the fuel is not broken into a particularly fine spray or mist the resulting mixture cannot be homogenous.

The particles of hydro-carbon at the center of a fuel globule cannot combine with the oxygen of the air and with a large globule it takes the air longer to reach the center.

Much of the fuel that goes into the cylinder in a liquid state passes out through the exhaust without being burnt. It is thus a dead loss of power and efficiency.

Precipitations are caused by a change in direction of flow; they are minimized by the application of heat.

The rate of flame propagation varies with the homogeneity of the mixture and is more rapid and regular when the surface to volume ratio of the globules of incoming fuel do not vary from one location to another.

IN Article I, published November 14, it was shown how the addition of heat is necessary in order to effect carburetion, and we will now more carefully consider the question of the homogeneity of an explosive mixture. It is essential that in a gas or vapor engine the working fluid should be supplied to the engine in as homogeneous form as possible, in order that the rate of propagation of the flame through the mixture may be uniform and of a maximum velocity. Particularly is this necessary in high-speed engines where the flame velocity has to be very great in order that the pressure should, as it were, keep up with the piston.

It has been found in practice that **where lack of homogeneity in the mixture occurs, the expansion of the burning gases is erratic, and produces humps on the expansion curve of the indicator card.** Sometimes these humps have been rather difficult to explain, but I think we may take it for a fact that they are due to variations in the stages of combustion of a liquid fuel due to the lack of homogeneity in it. We do not find these humps occurring in gas-engine practice to any marked extent, and where a hump has occurred it has been of a fairly regular formation, and may be due in some instances to the interchange of heat between the burning mixture and the cylinder walls.

We find, however, in an engine burning liquid fuel, that in some cases the hump is most marked, and one of the points which the writer raised in connection with a recent discussion on Herbert Chase's paper before the Society of Automobile Engineers at the June session was that the irregular formation of the indicator card was probably due to the lack of homogeneity in the explosive mixture which was produced by the particular carbureter fitted to the engine.

In further confirmation of this theory, Mr. Chase pointed out that the proportion of air to fuel was abnormally small for a high-class carbureter under testing conditions, and it is very probable that the mixture in this case was too rich on account of lack of homogeneity. That is to say, that certain portions of the mixture were abnormally rich in order that the other portion of the mixture should have the correct ratio of constituents.

It is difficult for our minds to consider the smallness of a molecule, but in the limit we may take it that an ordinary perfect gas is body divided into its finest possible particles. In a hydro-carbon mixture, gas with air, it is obvious, in order that the rapidity of combustion should be insured, that the hydro-carbons must be divided into the finest possible particles so that each molecule of hydro-carbon can combine at the critical moment with its necessary molecules of oxygen.

One of the objects of the carbureter is to break up the fuel into these finely divided particles in the limit into a gas or mist, and any variation from this ideà is a step in the downward direction in carburetion. **We come, therefore, to the question of surface to volume ratio, and it is a well-known fact that a sphere presents the smallest surface to volume ratio of any known shape.** If you study the formation which a liquid takes in issuing from an orifice or in moving through space or the atmosphere, you notice that the spherical form is always taken by the particles. **We have, therefore, as a peculiarity of nature, to deal with liquid which naturally presents to us the greatest difficulty with regard to its presentation of surface for the carbureting process.** We ought to divide these globules into the largest number possible in order to present a maximum surface of fuel from which evaporation can take place. **A simple law of mathematics shows us that the relations between the volumes of different bodies are to one another as the cubes of their diameters,** so that if we have a globule whose diameter is 1 in any particular units, and another globule whose diameter is 2, **the latter will contain eight times as much volume as the former.**

The importance of fine subdivision of the fuel in the carbureter itself is thus emphasized, as **it is obvious that those particles of hydro-carbon at the center of a globule cannot combine with the oxygen of the air until they are actually in contact with it.** This means that **the time element is proportional to the size of the globule, and where rapid carburetion takes place, either the subdivision of the fuel must be very fine, or an excess of fuel must be permitted to pass through the carbureter, the external portions of each globule only being correctly mixed with its necessary amount of oxygen.**

In this latter case either the fuel passes as liquid into the engine cylinders and is there burnt, causing distortions of the true expansion curve; or it passes away unburnt to the exhaust. It is my contention that **what I should consider a heavy fuel consumption with the majority of American engines and carbureters, is due to the lack of sufficient subdivision of the particles of fuel in the carbureters** themselves. Furthermore, in many cases, although this subdivision or spraying may take place in the first instance, its effect is nullified by obstacles presented to its path through the carbureter on the way to the engine.

We now come to a very important feature in carburetion, namely, the shape and condition of the flow path between the carbureter jet and the inlet valves. In the first place, there is undoubtedly an awakening in America to the advantages of the venturi-tube principle, which principle is a very old one in carbureter designs. I had a venturi-tube carbureter fitted on an early Decauville car 11 years ago. At the throat of this tube was a jet of the form of a mushroom valve. This instrument worked perfectly well when in adjustment, the upper taper of the cone in the venturi being 7 degrees.

A butterfly valve was fitted, which was fortunately very thin. **Here we come to the first possible source of trouble in an obstruction, as such an object right across the center of the flow path tends to cause precipitation of the finely divided particles of fuel held in suspension in the air.** At this early stage of the carburetion it can scarcely be said that the fuel is already evaporated, and it is my contention that even **a gauze screen does more harm than good.** Such a device immediately causes precipitation to start, affecting the homogeneity of the mixture by alternations of weakness whilst the liquid is precipitating, and richness when the precipitated liquid is dislodged by the air stream.

Such a state of affairs undoubtedly takes place whenever a change of direction in the flow path occurs, and it can only be minimized by the application of heat. **If heat is applied to a surface which tends to cause precipitation, the liquid on coming in contact with such a surface is evaporated. Modern carburetion owes much of its improvement to this fact,** and there is no doubt that the reason why certain six-cylinder block engines of modern type carburete more easily than the old induction-pipe engines is that very large heated passages are provided through which the carbureted air has to pass. Such passages, cored in the waterjackets of the engine, form ideal means for carburetion, by reason of the fact that the flow velocity is quickly reduced. A time element occurs in which evaporation can take place, and any precipitated liquid has an opportunity of diffusing throughout the whole mass.

A controversial point here arises, as to whether it is better to allow the mixture to enter the engine at practically atmospheric temperature, thereby getting the greatest weight of charge into the cylinders every time at full throttle opening, or to allow the mixture to reach a higher temperature, at which it is more perfectly carbureted, although the weight per charge is less.

I certainly am of opinion that the latter is the better state of affairs, as, although the weight of charge may be slightly less, due to its rise of temperature, the more homogeneous mixture in the latter case will burn far more efficiently. By this is meant that **the rate of propagation of the flame through a homogeneous mixture is more rapid and regular than is the case where the surface to volume ratio of the incoming fuel varies from one location to another.** It is a fact that with modern grades of petroleum distillates it is quite possible for the heavier fractions of the fuel to pass through the engine cylinders unburnt, but even if this ultimate state is not reached, retarded combustion takes place, resulting in an unduly high temperature.

(To be continued.)

Fundamental Principles of Carbureter Adjustment

ADJUSTMENTS on carbureters of all makes follow along the same lines. That is, there is a rational method of procedure, which, if followed, will permit of reaching the required result in a shorter time than if the hit-or-miss principles are generally followed. One cardinal point must be remembered in all carbureter adjusting, however, before anything else is considered and that is that a leanness of mixture should at all times be favored.

There should be three distinct points of adjustment: First, with the motor idling. That is, with the gears in neutral, the spark retarded and the throttle closed as far as possible. Second, at high speed with gears in neutral and spark advanced, and, third, accelerating on the road. The carbureter should function well under all these conditions and should not choke up or backfire when the throttle is opened and closed rapidly.

Start the motor going without changing the carbureter. If it is impossible to start the motor with this adjustment on the carbureter close the needle valve as far as it will go and then open two full turns on the screw that holds it. In general, on a carbureter it would be well to start with what looks like the medium adjustment on all the valves. The valves differ on all the carbureters on the market, and it is only desired to give a general outline of the process of adjustment so that any carbureter may be tuned up by simply carrying out the previously planned system.

When the motor is running, open and close the throttle several times with the spark set in different positions to see if any black smoke is emitted from the exhaust or if backfiring into the exhaust pipe occurs. **If backfires occur, the mixture is too lean and the needle or fuel valve should be opened slightly or the air valve closed.** Where the adjustments are made on the auxiliary air supply the tension on the spring should be loosened slightly so that the valve will open under less suction. If black smoke is exhausted the fuel valve should be closed. In the latter case the mixture was too rich and this is to be avoided carefully if the carbureter is to give the maximum economy. It is quite possible that too rich a mixture is being given without the exhaust of any black smoke and for this reason it is wise to close the fuel valve until the motor starts to backfire. The needle valve is then opened slowly until the backfiring just disappears.

When the motor appears to be running satisfactorily, try it idling as slowly as it will go. When it turns over smoothly, arrange the throttle valve-stop screw on the carbureter so that the throttle cannot be closed any further. This will prevent the motor from choking up and dying if left running at the curb for any length of time. Now speed up the motor and note if backfires occur. If they do, it will be necessary to tighten the air valve slightly. **In any case do not try to change the level of the gasoline in the float chamber for this is arranged at the factory and is in the best possible position for good results.** When the motor runs as well as it should on high speed, try it again on low, making whatever adjustments on the fuel and air valves that are necessary to secure smooth running.

The car is now ready to be taken out on a hill and given the final test. This is the accelerating powers on the hill. Start the car slowly on the hill and then press down on the accelerator pedal and note how it picks up. If the carbureter chokes and the motor hits on one or two cylinders and then starts to fire regularly, or perhaps continues to miss, the trouble is in the design of the carbureter or the mixture is too rich. **The carbureter should not be condemned, however, if it chokes when the pedal is pressed down as far as it will go immediately.** The accelerating should be done more gradually. When the pedal is pressed all the way down before the motor is moving fast enough to take care of the amount of fuel this will cause to be fed to it, the carbureter is almost sure to become choked.

It is very frequently found that the motor will hit on all cylinders at high speed but that at low speed it will miss badly. This is not due to carbureter trouble in a great number of cases, but to the fact that one or more of the sparkplugs have too large a gap between the electrodes.

Foreign Constructions Designs and Practices

The French School of Engineering

American Engineer Analyzes Features of French Designers and Makers—Delahaye Crankshaft Details—Gearbox Bearing Supports—Accessible Combustion Chambers—Well-Made Air Pumps—Gasoline Tank Locations

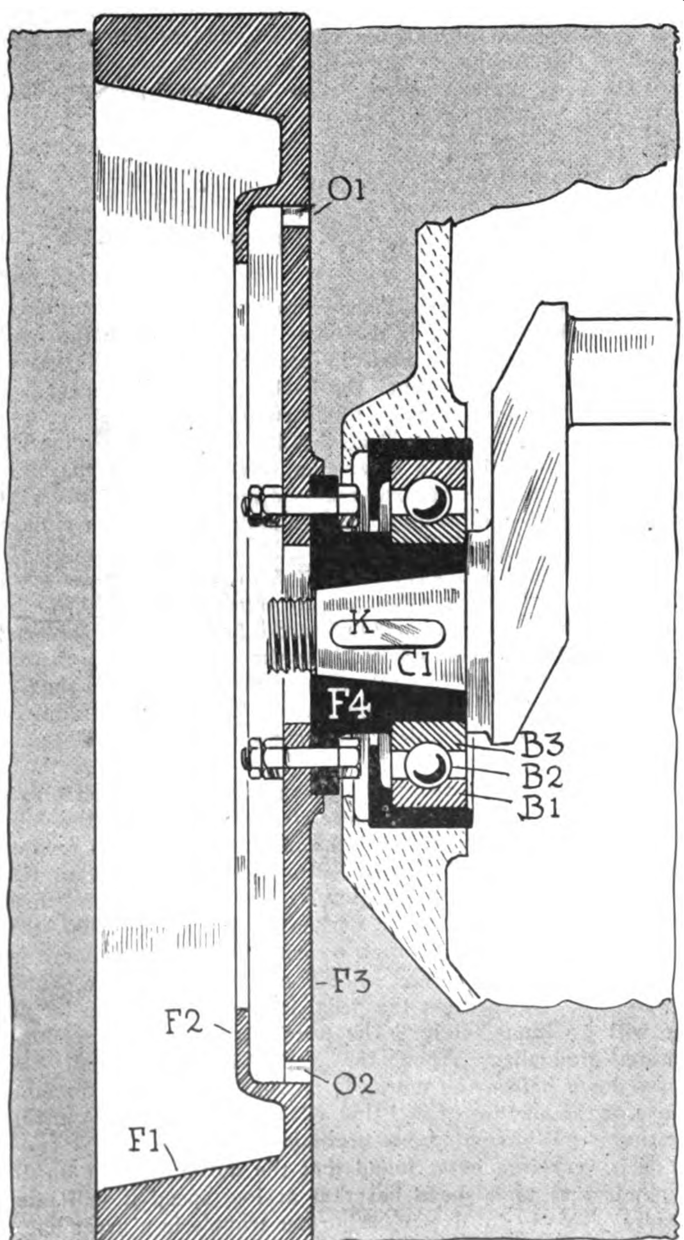

Fig. 1—Delahaye flywheel attachment to crankshaft

IT is in the detail that success or failure lurks. French engineers pride themselves upon their clear understanding of this point. It remains, then, to look at the French method of disposing of details, and learn by so doing how they think and what they accomplish. That there should be a profit in the enterprise must be true. If the French school of designing is far advanced it may be copied with profit. If there are glaring inconsistencies, to unearth them is advantageous; the process will help all around. Then, too, by open discussion, if through some lack of good understanding our appreciation of some of the French methods is to do them an injustice, it will be timely to listen to their explanations to the mutual profit of all parties.

That the French should explain the points that fail to satisfy our understanding must hold so long as French automobiles are offered to our purchasing public. Moreover, we expect to broaden our knowledge of the intricate detail of automobile designing by closely scrutinizing French effort, and it is only fair to them that any little misunderstandings should be wiped out.

With this brief introduction merely to establish the position that we take respecting the subject matter presented here, it remains to introduce the points to be enlarged upon, and for purposes of clearness resort is had to a series of sketches showing as closely as possible how French engineers do their work.

Attaching the Flywheel

Fig. 1 is a section of the crankshaft of a motor at the flywheel end, the flywheel and the crankshaft ball-bearing. showing the method used in assembling as it is brought out in the Delehaye motor of the type offered for use in the postal chassis. The flywheel F1 is of relatively larger diameter with more than the usual amount of metal in the rim. Means are provided for disposing of any lubricating oil which may fall on the flywheel. The flange F2, on account of centrifugal force, forces the oil in the diametral direction and, as it sweeps into the pocket formed by the flange facing the flange proper F3, it accumulates until a sufficient excess is stored, when this excess flows out through holes o1, o2, etc., drilled in the flange F3. The flange F3 is not dished. Since internal strains due to unequal cooling are set up in all castings during the foundry process, and, in view of the absence of any dishing to permit of strain compensation, it must be taken as true that the strains, such as they are, will reside in these flywheels so made, after the automobiles are delivered to users. It would appear, under the circumstances, that French foundry practice must be so perfected that, by a system of uncovering the metal, which requires precision of workmanship, the metal is cooled fast or slowly over the several zones in proportion to the ratio of surface to mass, sufficiently to save undue internal strains; otherwise flywheels so made must be regarded as bordering upon the unsafe.

The flywheel flange is bolted to a separate hub-flange F4, the latter being on a taper of the crankshaft end C1, and a key K is provided as a further means for preventing rotation of the flywheel on the shaft. It is obvious that the designer is a firm believer in flange-bolted fastenings for flywheels on crankshafts. The effect of this construction is contrary to the designer's express preference. The fastening, taking it as a whole, is that of a taper fit. It is easily seen why the benefit of a flanged fit is lost. The crankshaft is of the ball-bearing type, and in order to locate the ball-bearing it was found necessary to interpose the separate hub with its integral flange F4, and Fig. 1 shows how the inner rod B3 of the ball-bearing is clamped between the shoulders of the hub F4 and the crankshaft C1.

Method Aids in Assembly

The advantage of this method of assembling is one that the salesman can readily appreciate. After the motor is assembled and put in the chassis the casual observer will only be able to see that the flywheel is flanged and bolted to its mate-flange on the crankshaft; but there will be no way of telling that the flange F4 is separate and that, after all, everything depends upon a taper fit of the hub on the shaft end.

Referring now to the ball-bearing, it is true of this construction that it is of large diameter, and service conditions exact just this large diameter of ball-bearing. It is also true in service, as experience has adequately shown, that the inner race B3 of the ball-bearing must be clamped so tight that rotation of the race on its fit will be prevented. The design, however, makes no suitable provision for clamping because it is impossible, in practice, to make a taper fit that will be at once a tight fit and at the same time permit of a fixed travel of the hub on the shaft. If the hub fetches up on the taper of the shaft before it does against the shoulder on the hub clamps the inner race B3 of the ball-bearing, the latter will be free to thrash around, which it will not do for long without showing depreciation; but if the shoulder on the hub F4 fetches up against the inner race B3 of the ball-bearing this is a guarantee that the fit of the taper will be poor, if indeed, it may not be so bad that the key K will be left to do all of the work.

The outside raceway B1 is provided with a jacket of steel, the latter being a tight fit in the base of the aluminum crankcase. If the outer raceway B1 is a tight fit in its jacket of steel, then the axle alignment of the inner raceway B3 with the outer raceway B1 may be such that the balls B2 may be pinched, or the orbit of the balls formed by the two races may be elliptic—the result will take the form of damaged balls. On the other hand, if the outer raceway B1 is a sucking fit in the jacket, then, as experience tells, the race race will pound around in the jacket until some serious mishap sends the motor to the repair shop.

Good Engineering Indications

It will appear from what has been said that the designer in this example picked out a particularly difficult task for his day's work. It would be doing scant justice in this instance not to mention the excellence of proportioning, the eye to exactness, and the generally good completion of the whole undertaking. If there are questions to be answered they have to do with the scheme of design, the principles involved and the expediency of plan involved.

In order to gain further knowledge of French practice, Fig. 2, showing a part of a gearbox in section, is shown. This illustration raises two important questions: First, referring to silence or the reverse, noise; and, second, uniformity of design or, in its absence, there is the expedience of special grades of materials.

The design shows the shaft S1 in its relation to the stubshaft S2 with a ball-bearing intervening in the usual way, the latter being housed in one of a pair of connecting gears. The stubshaft is provided with a pair of ball-bearings B2 and B3, and they are far enough apart to assure a good result. The stubshaft S2 has four diameters, the largest diameter being in the ball-bearing B2, reducing to the diameter of the pore of the pinion P1 of the constant mesh or master gearset, which imparts rotation to the layshaft S3; then the stubshaft S2 is reduced in diameter to facilitate assembling and to accommodate the ball-bearing B3, and this shaft is again reduced in diameter to fit the universal joint member J1.

The plan of construction necessitates these reductions in diameter of the shaft S2, it being necessary to provide for the inner races of the ball-bearings among other points. It must be obvious to the reader that there is a striking lack of uniformity in the strength of the shaft in its relating sections. This defect is all the more significant if the mind reverts for a moment to the fact that the strength of a round solid section changes as the cube of the diameter.

Then there are three abrupt changes in the diameter of the shaft, and as a result, as many shoulders to serve as starting points for cracks, and these cracks are all the more likely to be experienced since the shaft has to undergo heat treatment, the latter being necessary to insure service of the clashing gear on the end of the shaft. True, the designer had no alternative in this case. To get away from the char-

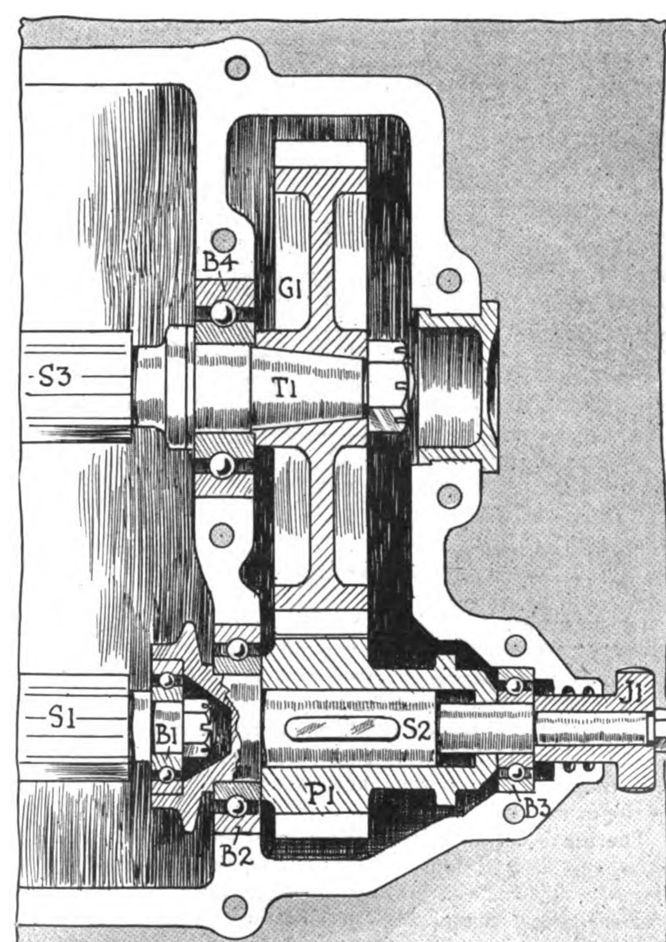

Fig. 2—Part section of Delahaye transmission gear, showing how the shafts rotate, details of design and fitting of relating members

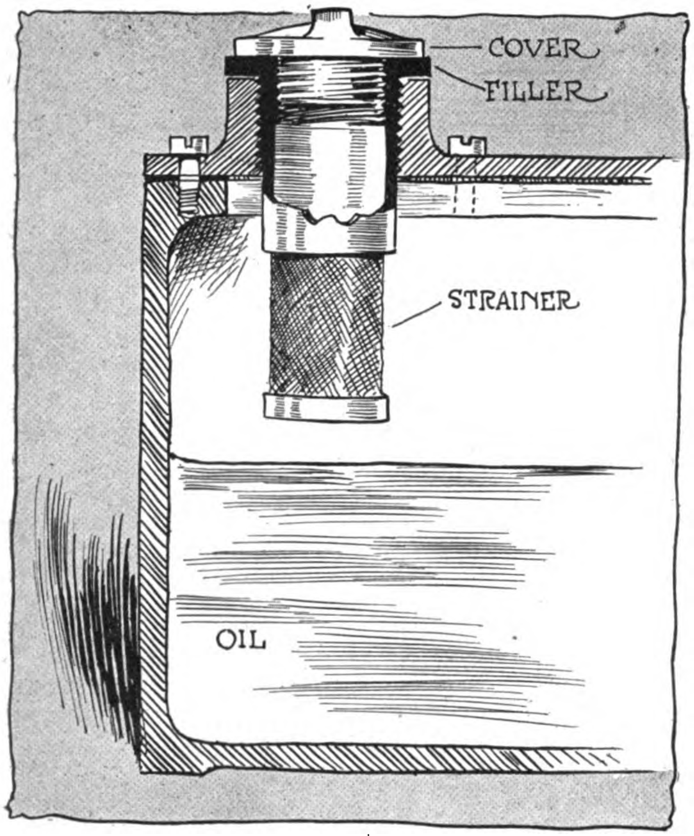

Fig. 3—Oil reservoir of Vermont motor, showing filters for the oil

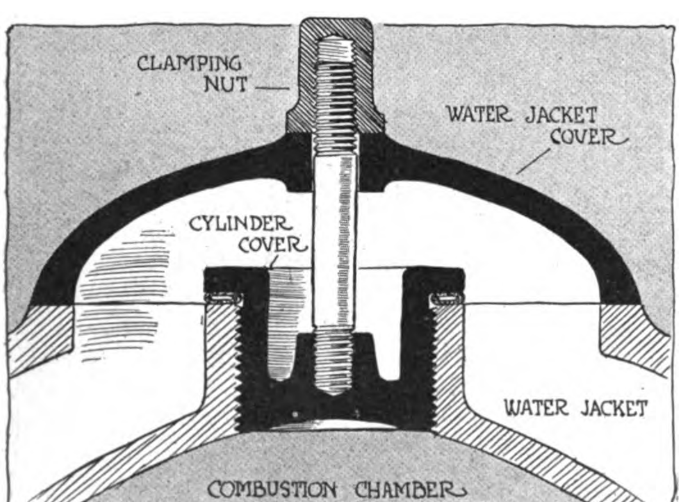

Fig. 4—Securing cylinder-head plug in Cottin & Desgouttes motor in 16-horsepower chassis

acteristics here brought it would be necessary for him to make a new start along more promising lines.

Referring to the important subject of silence, this condition must be difficult to fix in the type of gearset here illustrated, because the gear G1, on the layshaft S3, is pressed up on the tapered end T1 of the shaft, which overhangs the ball-bearing B4; the shaft, in consequence, is unsupported in the plane of the master gear.

There are certain details which receive excellent attention from this illustration, namely, the designer shows by the use of a taper T1 for the gear G1, on the shaft S3, that he has a liking for tapers. The question is, why does he so willingly give up the taper idea when he applies his skill elsewhere, as in the fitting of the pinion P1 on the stubshaft S2; and, too, in the fitting of the universal joint member J1 on the end of the same shaft? On the other hand, why

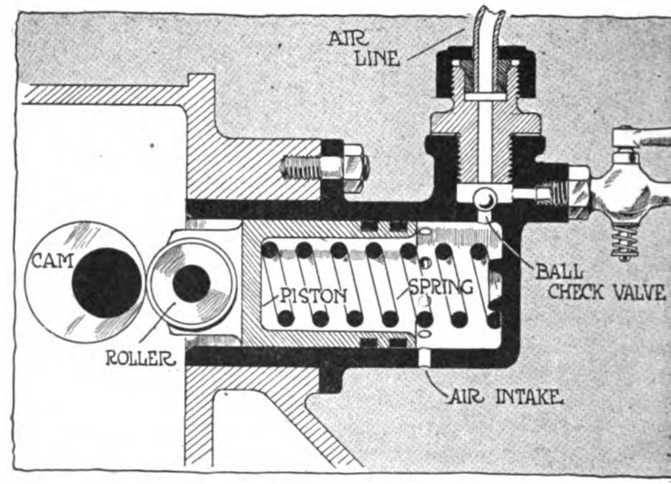

Fig. 5—Air pump in Panhard, showing the piston actuated by a cam and a spring for returning the piston

bother with a taper on the relatively unimportant end of the shaft S3, if a taper cannot be used for the universal joint member?

There are certain details which receive excellent attention in the French school. Fig. 3 will suffice for the moment to make the point. In this illustration the lubricating oil for a motor is shown in a sectional reservoir, partly broken away, and the filler is provided with a filter or strainer, so designed that the strainer may be screwed out, cleaned and put back into place ready for further service in a moment. The oil is put into the reservoir by unscrewing the cover on the exterior of the strainer shell to afford the desired opening and fine mesh gauze is wrapped around the exterior of the shell to serve as a filter. The oil goes into the shell, and, to get to the main body below, it must pass through the gauze. Any dirt is left behind in the shell.

Points in Cylinder Castings

There are certain details which receive excellent attention which are never above suspicion. Take cylinders, for illustration. The practice is to cast the cylinders with a core-hole in the head, it being desirable, if not actually necessary, to fix the core to keep it from displacing by means of a tapered core connection passing through the head of the cylinder, hence the necessity of hole in the cylinder head. **If a hole must be allowed for, the further reasoning is, why not make it large enough in diameter to accommodate the boring for which it is used in the process of rough-boring the cylinders during the finishing interval?**

But the hole in the head is, unfortunately, an opening in the cylinder wall just at the zone of greatest pressure and maximum heat-change, as well as highest temperature, the latter, in internal combustion motors, following as a matter of course. If the cover is not tightly fitted, or if it will not remain tight under service conditions, compressed liquid will escape during the compression and power cycles, and water will enter during the suction cycle. Either of these incidents will suffice to thwart the operation of the motor.

Leakage, due to defective cylinder-head plugs, is still a common trouble of motors, even after 20 years of practice, and French engineers, recognizing this fact, are still on the hunt for something more secure than either of the ordinary methods in vogue. Fig. 4 presents, in section, a cylinder of a Cottin and Desgouttes motor, showing how this firm of the French school approaches the subject. The cylinder-head cover, Fig. 4, is screwed into the cylinder. The water-jacket is provided with a separate cover. A stud is screwed into the cylinder-head cover and a clamping nut on the other end of the stud is screwed down against the waterjacket cover. The adjustment when made presses the waterjacket cover more or less firmly into place. But all of the pressure exerted by means of the clamping nut on the stud is offset by an equal and opposite force which tends to pull the head out of the cylinder. This pressure is in the same direction as the pressure exerted in the cylinder by the liquid when it is compressed, ignited and burned. These efforts combined tend to strip the threads of the cylinder-head cover and the mating threads of the hole in the cylinder head.

Good Airpump Design

It is not without profit that some of the French cars are examined. They conceal jewels of designing. Fig. 5, a Panhard airpump, shows one of these nuggets! This pump, shown in section, comprises a piston in a cylinder actuated by a circular cam eccentric to the camshaft of which it is a part. The roller, concentric with its pin, the latter passing through a pair of ears extending out from the piston head, is pressed against the cam by spring pressure from a stout spring located within the piston, bearing against the head of the piston at one end of the spring; the other end pressing against the head of the cylinder, the piston is inverted. Air enters through holes in the cylinder wall uncovered by the piston when the same is at the inner end of the stroke as shown. The air is compressed when the cam rotates, pressing the piston out against the spring. The ball check valve is lifted off of its seat by the compressed air which passes on through the air line to the gas line tank. The piston is packed tight enough to hold pressure up to the requirement. The pump is small, with simple construction features, and, in operation, is noiseless. **The advantage of clean air over foul liquid of combustion from the cylinders of the motor for use in the gas line tank is obvious.**

Panhard Clutch Coupling

An excellent piece of designing at a point where strength is necessary is shown in Fig. 6, a Panhard 18-horsepower gearset, showing, in section, the shaft detail as it extends forward to the flanged joint. Attention is called to the bell-shaped flange F1, integral with the fluted extension or hole H1, mating with flutings of the shaft S1, with a nut N1 of the castellated type on the end of the shaft, by means of which the flanged hub is forced against the shoulder S2 of the shaft S1, with an accommodation piece A1 intervening. The second function of the accommodation piece A1 is in conjunction with the thrust ball bearing B1, spacing it in its relation to the annular type ball bearing B2 and the relating mechanisms of the clutch, which, in this example, is placed within the same housing—the clutch is of the multiple-disk type.

But the point which it is proposed to bring out here lies in the excellence of the flanged connection and the generally uniform proportions of the parts. The flange, considering the use of an extension member reaching to a mating flange of the shaft extending back from the motor, affords ready means of removing either the motor or the gearbox unit from the chassis without disturbing the remaining unit.

Dash Gasoline Tank

The desire to place the gasoline tank in the space made by the overhang of the dash is strong. Not a few examples of this idea are bad. Fig. 7, of the tank, as it is located in one of the Delahaye models, corrects the trouble usually experienced. The tank is situated on the side opposite the driver. The pipe, as shown, has a goose-neck bend in it, which saves the pipe from the ills of vibration.

Where to put baggage, or how to do without it, is still on the list of pressing problems to be solved. Fig. 8 is a rough approximation of one man's methods. He was sitting on a mile-stone which indicated that it was 14½ kilometers to Paris when interviewed. The car was considerably encumbered as illustrated. The tourist, a well-known American, said, "I would be all right if I didn't have so damn much tire trouble." The ladies in the party voiced the same sentiment with their eyes.

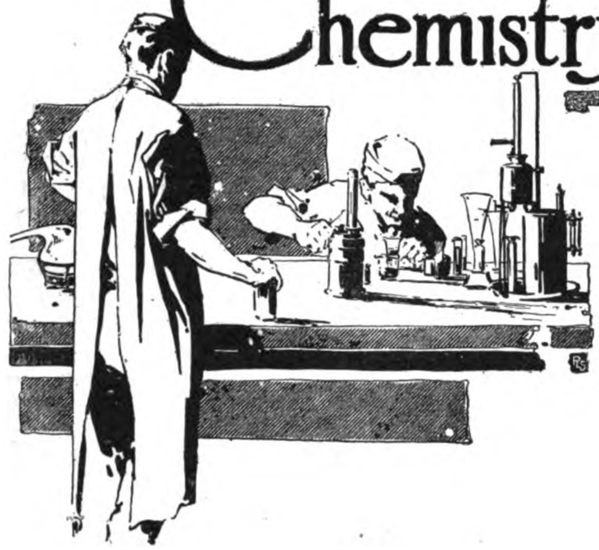
The Chemistry of Cylinder Oils



Nomenclature Not Borne Out by Analysis in Heavy, Light and Medium Oils of the Same Make and Brand

Part V

Being the fifth of a series of articles on cylinder oils which will appear from week to week. Discussions are invited and the columns of THE AUTOMOBILE *are open to pertinent criticisms.*

By W. Jones

IN this article we give the analysis of 28 samples of oil. These samples were all obtained in Detroit, and, with the exception of the last three, or brand N, are supposed to be the same oils as those published last week. They come to us under the same name and grade. While the brands are all represented, the different grades are not all present. This is on account of it being extremely difficult to obtain samples of oil from dealers, for analysis. Just why this objection should exist, we do not understand, except that the oils being handled are not what they are represented to be. That this may be the case seems highly probable, and this view is well borne out when we compare the Detroit samples with the New York samples, or we may even say when we look over the table of Detroit analysis.

We will first make a little comparison between the two tables. In table B which appeared in the November 21 issue of THE AUTOMOBILE, and which shows the New York oils, we have in brand A, eight samples or grades, and these same eight grades are shown in table C, which gives the oil as obtained in Detroit. The gravities in these two lots of oils are fairly well alike, and we think as close as might be expected in commercial samples. When we come to the viscosities at 80 degrees Fahrenheit, more difference is shown; the two white oils being considerably thicker in table B than in table C. Coming to Nos. 1, 2 and 3, we find the reverse; table B being made up of thinner oils than table C. **But when we come to No. 6, the extra-heavy oil, we have a difference which is so great that we can hardly think it is the same oil, or anything like it.** This is also shown in the flash and fire points. However, taking this brand as a whole, with the exception of this last sample, these oils agree fairly well.

In brand B, there is only one grade of **this oil put up.** This oil is well represented as we have **two samples from** each city, but it is strange that in **New York the oil is** heavier than in Detroit, although the **first sample is about** the same as the second one in Detroit. **In this brand, the** first sample on the New York table is a **sample direct from** the works, and we therefore consider **this the correct oil.** This agrees with the second sample from **Detroit. The other** two are simply mixed oils and not this **oil at all, one being** lighter and the other heavier. Consider**ing the parties who** put these oils up, we think there is but **little doubt that it** can be obtained of the same quality all **the time, or very** nearly so.

In brand C, we have Nos. 1, 2 and 3, **or light, medium and** heavy, in duplicate from New York, **and the same three** grades from Detroit. The first three in the New York table are from the parties who put up the oils. The others are not. The second three New York oils are heavier, while of the three Detroit oils Nos. 1 and 3 are simply absurd imitations.

In brand D there is only one grade put up. The sample in the New York table is from the makers, and although a little thinner than that from Detroit, the two agree very well.

In brand E we have in table B Nos. 1, 2 and 3, and in table C only Nos. 1 and 2. The makers of this brand of oil in New York refused to give any samples for analysis. The samples, however, were obtained, with their labels (the labels of the makers) and as far as we could see came from their works. These are shown in the New York samples. **In these samples light, medium and heavy do not seem to mean much of anything, as the medium seems to be lighter than the light. Turning to the Detroit table, we find both No. 1 and No. 2 to be absolutely the same oil, which does not agree very well with any of the New York grades.**

In brand F, we have in table B three samples Nos. 1 and 2; No. 2 being in duplicate. They are supposed to be the same oil, with the exception that the second No. 2 has had an acid treatment, while the first has not. This acid was found in the oil, as it seems that it can never be wholly removed. The analysis of these two samples show them to be practically the same oil in all respects, but when we turn to the Detroit sample, there does not appear to be the least resemblance, except in the gravity, and we do not think it would take much stretch of the imagination to say that this oil is the same as the last two, or brand E in the Detroit oils.

In brand G, we have for comparison Nos. 1 and 2. In both cases, both New York and Detroit, the oils come through dealers, so there can be no certainty as to what we have. However, the three New York oils seem to run fairly well from light to heavy, and would appear to agree very well with the three grades in other brands. Turning to the Detroit table, we have Nos. 1 and 2, but do not find the least resemblance to the New York samples, while in No. 1 we again have the same oil as in the last two brands, No. 2 being a very different oil, as is shown by the gravity and the viscosity, and also by the fact that it does not contain any sulphuric acid, while all the others do.

In brand H we find three samples from the oil company in the New York table, and only No. 2 from the Detroit company. These two No. 2 samples we find to vary all the way through, and also find that the three New York oils have had no acid treatment, while those from Detroit have had it, ıd again we do not hesitate to say that this is the same ıl that we have had in E, F and G.

In brand I, we have three samples on the New York table, ·hich came from the oil company. **The viscosity in these amples show a wider variation than in any other oils we ave had.** In the No. 3, or what is marked heavy oil, the iscosity is 54.6428, and in these three oils No. 1 has had cid treatment and contains sulphuric acid, while Nos. 2 and have not been so treated. Now, when we compare this Vo. 3 oil with the No. 3 we have in the Detroit table, we ınd a viscosity of only 4.8214. This, at first sight we thought night be a mistake in the marking of the oil before being ·ent; but it does not agree even with No. 1, except in gravity.

In brand J, we are again not sure of our samples. The New York samples came through a large dealer, but were ıot original samples. Therefore there is doubt as to their ɔeing true samples. The two New York samples are very much alike, partcularly as to viscosity. The two from Detroit are also very much alike, but differ very much from New York, both in gravity and viscosity. Neither of the two New York samples contain sulphuric acid, while both samples from Detroit are full of it.

In brand K, we have only one oil for comparison, No. 2. These oils are very different, not only in gravity and viscosity, but also in that the New York oil does not show sulphuric acid, while the sample from Detroit does.

In the Detroit oils if we compare the brands I, J and K together, and note the fact that they contain about the same amount of sulphuric acid, it would look as though they were practically the same oils, and we will further say that we think they are **the same oils that we had in E, F and H, only mixed with a little lighter oil.**

Brand L, contains only one grade, and we have the same grade from both New York and Detroit, but as neither are original samples, again, we are not sure of them, although the New York sample came through a large dealer and we think is all right, and as we come to the bottom of the list, it is somewhat of a relief to have two samples from the two cities, which are very nearly alike, and without acid.

We notice two points in these two lots of oils. First, the carbon figures in the Detroit oils as a whole are lower than those we had in New York. This would seem to be largely due to the oils from brand E to K being practically the same oil, and an oil giving a low carbon.

The second point, which is due to the same cause, is the large number of Detroit oils which have sulphuric acid in them. We have in the twenty-eight samples fourteen which have the acid, while in the New York samples there are only eight out of forty samples carrying the acid, and in four of these there are only traces. This acid, of course, has been added in the treatment of the oil, and it seems that after this acid treatment, it is not possible to remove the acid entirely, by washing. This small amount of sulphuric acid does not appear to be any more harmful than to slightly corrode the cylinder, and this corrosion is not very heavy, but its presence is an easy means of deciding between an acid and non-acid treated oil, and if we are expecting to get a certain oil which we know is a non-acid oil and get one containing acid, we are certain we are not getting the oil we expected. It makes no difference if the dealer considers the oil just as good or even better. When a certain make of oil is called for, that is what we should get. That this is not always the case, may be shown in the following.

In the New York oils we have the acid, present only in the eight cases shown in the table, while in the Detroit oils we have it in many more oils which are supposed to be the same. The brands of oils in the New York table which show this acid also show it in the Detroit table, and in addition to these, the Detroit oils show it in the following brands where the New York table does not.

Brand A, No. 2; brand C, Nos. 1 and 3; brand E, No. 1; brand F, No. 2; brand G, No. 1; brand H, No. 2; brand I, No. 1; brand J, No. 1, and brand K, No. 2.

Here we have a list of ten oils, which by this one test alone cannot be the same oils as those obtained in New York under the same names. Therefore, unless you are dealing with a reliable party, it is useless to think you are getting what you want, or what you are paying for, and, as in the case of the Detroit oils, where without doubt many of the oils came out of the same lot or barrel, you may be getting the same oil you want as far as the label is concerned, and no more.

(To be continued.)

The Joining of Metals

A Description of the Three Groups of Processes, by Means of Which Metal Parts May Be United

Ordinary Cementing, Autogenous Fusing and Cementing Under Pressure Are Applied in Different Instances

Extract from a paper read before the British Institute of Metals by Alexander E. Tucker, F. I. C.

THE methods in practical use for joining metals may be divided in the order of their importance as follows:

1. **By metallic cements,** such as tinman's or brazing solder, which have to be brought to the plastic or liquid state, and whose constituents should be capable of alloying perfectly with the metals to be joined.
2. **By autogenous fusing,** in which the two parts are heated and liquid metal of the same character run around the mass, or the parts are heated to fusing point, and the surfaces worked together by pressure or hammering.
3. **By the use of a cementing metal under pressure,** generally that of a rolling-mill, and at ordinary or only slightly raised temperatures.

In respect to the first method, it is obvious that the fusion point of the solder must be lower than that of the articles to be joined, and as, speaking generally, the higher the melting point the stronger the solder, it follows that **it is desirable that a solder or brazing spelter should be used whenever possible, the melting point of which is only a few degrees less than that of the metals to be joined. The solder should also have, if possible, the same characteristics, such as malleability, color and hardness.** Such conditions imply greater skill on the part of the operator, but the union will be the more perfect, and the process under such conditions more nearly approaches autogenous soldering.

Tinman's Solder—Field and Use

Tinman's Solder—In the use of this care should be especially taken to avoid the presence of zinc, and in certain cases even a trace of zinc is especially prejudicial; it thickens the solder, and probably on account of its liability to oxidation forms a superficial scum which the ordinary spirits of salt is incapable of dissolving. If the presence of zinc be suspected, the addition of a few drops of acid will help greatly. Antimony is frequently present in tinman's solder—this, by forming a cement of higher tensile strength, may, under special conditions, make a joint of greater strength. **In the use of solder—either soft solder or brazing solder—it is clearly the correct method to raise the work to the highest temperature that the solder and the work will stand, because under such conditions the penetration of the solder into the surfaces to be joined will be better, and further, the soldering medium may then be squeezed out to the maximum from between the surfaces by suitable means, and hence the requirement can be met, that the thinner the layer of cementing material and the closer the surfaces are together, the stronger the join. Additional strength, because of the additional intimacy effected, may be given to the work by rubbing the surfaces carrying the liquid solder together;** in the same way it is always well to rub the soldering iron, when possible, over the work when it is used, the wetting of the surfaces is then more perfect, and no stripping of the solder is possible when this rubbing is done. In order to obtain a lower melting point in tin solder, bismuth, and sometimes cadmium, is added. Such solders are used for delicate work, as is occasionally required for electrical fittings.

Bicycles have been built in which the tubing was fixed in the respective lugs with soft solder instead of the ordinary brazing. They stood every test.

The conditions here are very different from those in the case of the brazing of brass and copper, because it happens that all the metals employed in brazing and tinman's solders destroy the character of the steel they are intended to join if they are heated sufficiently with the steel, while they have no corresponding injurious effect when used for brass or copper work.

When soft solder is used the thin gauge tubing is not so likely to be spoiled by deteriorating action on the steel, or by being oxidized at the heat necessary for brazing; and, further, on account of the greater liquidity of the soft solder, it will, when properly applied, sink into the small annular space between the lugs, etc., and the tubes more completely than can be expected with the more viscous flux and brazing solder. The reasons that soft solder is not used for such work are, firstly, because the heat of the enameling stoves makes its use risky, and secondly, popular prejudice—a soft soldering frame sounding badly to the untechnical layman.

It is a common habit of workmen, and amateurs who have soft soldering to do, to depend on the ordinary bit, when they might **use a Bunsen or blowpipe. These, in many cases, would heat the work more generally than is possible with the bit, and would allow of the penetration of the solder into the surfaces, and the subsequent squeezing out of the excess of solder.** . . .

On the other hand, many forms of soldering bits are now in use, in which a Bunsen burner connected with a light flexible tube is employed to heat the bit, and the flame can be conveniently made to heat the work as well. This form of soldering iron has many advantages. One of the best fluxes I have found for ordinary soldering can be easily made by macerating flux skimmings from galvanizing pots with weak hydrochloric acid. On filtering, the solution is ready for use, and is an ideal flux, because of the chloride of ammonia present with the chloride of zinc. No iron or lead is dissolved if the acid added is not in excess. Solder is often used in the form of granules or strips of various sizes, and in this form is very convenient for routine work. In the case of spectacle frames or other light articles a large amount of work can be prepared, on each of which a small piece of solder, either in the form of a granule or a strip, is placed with flux on the part to be joined. The articles are then put in a tray, which is afterward taken to a muffle working at a convenient heat, or in some cases it is sufficient to put the work on a metal plate, heated by a gas flame or even a spirit lamp. Brass tubes are often made by bending the strip through dies and fixing a wire of suitable composition in the overlap with borax, or the borax may be mixed with finely granulated spelter. On passing the work through a furnace to raise it to a red heat, the spelter runs perfectly and a good join is made. The flux is then dissolved off the work and the tubes are finished by drawing through dies with or without a mandrel.

The best brazing, if it may be properly so termed, is done with "silver solder," thus the blading used in turbines is all fixed with silver solder. It is, of course, of the utmost importance that the small pieces used in the construction of turbine motors shall be immovably fixed and cemented in position, on account of the heat and centrifugal strain to which they are subjected. Various silver alloys are used, but they are generally about 60 of silver, 23 of copper and 17 of zinc, the flux used being borax, or borax and carbonate of soda. Such a mixture is remarkably liquid when in the molten state, and on this account penetrates interstices which ordinary brazing spelter would fail to fill.

Composition of Brazing Solder

Brazing Solder—**The composition of ordinary brazing solder ranges** within wide limits; the analyses of samples I have examined show **a variation from 61 to 33 per cent. of copper and 39 to 67 per cent. of zinc. The tin may vary from nil to 14 per cent. and the lead from nil to as much as 3 per cent. Any of such metals may be and are used for brazing, in accordance with the character and requirements of the work to be done. The higher the percentage of copper the higher the melting point, and the higher the percentage of tin the lighter the color.** We thus have a very large series of alloys available for very varied requirements. The presence of other metals when in small amounts is often of no consequence in the brazing of brass or copper, though obviously in all cases it is very desirable in important work, such as the brazing of high-pressure steam-pipes or where great strength is required, that the composition of the brazing metal shall approach as closely as possible to that of the metal to be joined, as only under such conditions can the maximum strength of the joint be obtained, and it is the non-observance of these conditions which has led to disaster. The skill of the workman is often limited to the fluxing of the solder, and seldom extends to an appreciation of its composition.

When, however, we come to brazing iron and steel the importance of purity is very much greater, and I have found the presence of tin in brazing solder intended for bicycle frames to be very injurious. The explanation is probably to be found in the extraordinary deleterious effect of tin on iron and steel. It is well known that a very small amount of tin scrap, if allowed to get into a bath of molten steel, will make it very red short, and when brazing solder containing as little as 0.5 per cent. of tin is used for brazing bicycle frames I have found that the joints are very unsatisfactory and unsafe.

An ingenious method of making a brazed joint is by connecting the two parts to be joined with the terminals of a suitable dynamo. On account of the local resistance the two parts become heated, and if suitable brass wire is wrapped round the object and the whole surrounded with a reducing gas, such as hydrogen or coal gas, a very perfect joint is obtained without any borax or other fluxing medium.

The reducing gas under such conditions will ensure the absence of any oxide of iron or other metal used, and no previous cleaning is required. Such method of joining has the great advantage that there is no borax to remove from the joint. On account of its great hardness this removal of borax is a serious matter, and much money has been spent on experiments to remove it by pickling and other methods. It is best removed by sand-blasting, the whole frame being so treated leaving an excellent surface, on account of its roughness, for enameling.

Liquid Brazing—Several patents have been taken out for details of apparatus in which a bath of brazing spelter has been kept liquid. The parts to be joined are dipped in the molten metal, the metal being prevented from adhering to the parts that have not to be brazed by applying a coating of blacking to them. The advantage of this method consists in the fact that less metal is used in making the joint, as so little is lost in applying it, and also the heat is general on the joint instead of being local, and I have no doubt that on routine work the consumption of gas for heating is less than when blow-pipes are used, and, of course, blast is not required.

Brazing by Copper-Wire Pieces

A modification of brazing is the use of copper in the form of sheet or wire. Under the Simpson patents tools are thus made in which the cutting part is a small piece of high speed or other steel, while the shank is mild steel or iron. In making, say, a lathe tool by this process, a bar of square mild steel is taken, and a channel planned or milled out on it in which a suitable square piece of high-speed steel fits. The two or three sides being clean, strips of copper are fitted in with a special flux, and the whole highly heated to the fusing point of the copper. After welding, the compound tool is cleaned up and treated for hardening and tempering in the ordinary way. There are some features about this process of building up tools which seem to have considerable merit. First, if ordinary brazing were used, the hardening of many tools implies such a temperature as would often destroy an ordinary brazed point. The zinc would possibly be volatilized, which is not the case when copper alone is used, the temperature of fusion of the copper being so much higher. Secondly, it is conceivable that the weld would be considerably stronger than with an alloy of zinc, because while copper alloys to a considerable extent with iron, the same cannot be said of zinc, which therefore under such circumstances would become a deteriorating element. Thirdly, the saving of expensive material, such as alloy steel, must be considerable in the case of heavy machine tools, as only a small portion of metal is ever in actual use. In a sense, therefore, the shank becomes a tool-holder without the disadvantages of the latter in respect to unsteadiness, difficulty of setting, etc. The process lends itself to many interesting applications, thus milling cutters may be made having a core of mild steel instead of tool steel. Hardening and tempering such cutters is a source of much difficulty and loss through distortion and cracking, and if the compound cutters can be so produced the possible economy should be considerable. There is no doubt as to the perfection of the join, as I have seen pieces of steel joined by the process which on splitting did not part at the weld, the original metal appearing to be the weaker material.

A process has been invented by F. Pich (Berlin) for the hard brazing of cast iron in a smith's hearth. The patent consists in the decarbonization during brazing of the cast iron surfaces to be united, and in bringing at the same time the molten brass solder into close contact with the cast iron surfaces which are decarburized, but without exposure to the air. For the decarburization of the surfaces copper oxide is used, which is mixed with borax, as a flux, until it has the consistency of a paste. This is applied to the surfaces to be joined, which must first be carefully cleaned. The cast iron pieces are then firmly tied together with wire and heated. The borax first melts, protecting the surfaces from oxidation, and taking up any oxide that may be still clinging to them. It also precludes the attacking of the copper oxide by the oxygen of the air. As the heating proceeds the copper oxide fuses and gives up to the now red-hot surfaces its oxygen, which combines with the graphite of the cast iron forming carbon monoxide and dioxide, while the metallic copper is set free in a very finely divided state. This alloys with the brass solder as it melts when strewn on, and the new alloy combines with the decarburized iron of the surfaces which it is desired to join.

Specimens of cast iron united by this method were prepared and subjected to tensile and breaking tests, and a **summary of all the results shows that when the brazing of cast iron pieces is carefully performed according to the details given by Pich, the strength of the pieces so joined is virtually equal to that of the solid material.**

As is well known numerous patents have been taken out, and numerous mysterious mixtures have been advertised for the so-called soldering of aluminum. In nearly every case the result is that, while fairly satisfactory for a short time, the join failed after a time, varying from a few days to some months. **One of the most severe tests to which such joins in aluminum can be subjected is that of warm steam. Joins which look well and are apparently mechanically strong, fail rapidly when submitted to this test.** In all soldering, it is obvious that the flux used must efficiently clean the surfaces of the metals to be joined, otherwise no alloying of the solder used with the surfaces is possible. In the case of aluminum very few materials adapted for such fluxes are available, the requirement being that they shall absorb oxide of aluminum. Another detail of importance is the great heat conducting power of the metal. A consideration of the results obtained with all the so-called solders of aluminum shows that the metal is so susceptible to electrical action and oxidation that the use of any metal in which aluminum itself does not preponderate is hopeless. The best results have invariably been obtained when the solder was of the same composition as the material to be joined. This condition involves the principle of autogenous soldering, which will be subsequently dealt with. The best flux used is a mixture of alkaline aluminum chloride, with the addition of fluorides, such as potassium fluoride or calcium fluoride. When these are mixed in suitable proportions and damped with alcohol, and heated on a strip of aluminum, the surface of the metal is cleaned perfectly. It therefore follows that if two surfaces of aluminum are so cleaned, and an alloy containing a high percentage of aluminum, with such addition of other melted metal as will reduce its melting point slightly below that of pure aluminum, applied with the flux named, that a very satisfactory join will be obtained. The heat such as from a spirit-lamp or Bunsen burner must, however, be applied from below the work. I have seen such joins made over a spirit-lamp which stood every test, including that of the steam test.

Difficulties arise from the presence of high percentages of aluminum in alloys in connection with soft soldering. These may be largely overcome by coating them electrically with copper. The following directions for soft soldering their alloys, containing from 5 to 10 per cent. of aluminum, have been issued by an electric smelting company:

"Cleanse well from dirt and grease. Then place the part to be soldered in a strong solution of sulphate of copper, and place in the bath a rod of soft iron, touching the parts to be joined. After a while a copper-like surface will be seen on the metal; remove it from the bath, rinse quite clean and brighten the surfaces. The surfaces can then be tinned in the ordinary way."

Uniting Lead Joints by Heat

It is obvious that these directions are intended to be used only where an ordinary electrotyping plant is not available.

The second method of joining metals referred to is that of autogenous fusion or running liquid metal of similar character on the surfaces to be joined, and in its simplest form is very old. It is illustrated in the case of repairing broken rolls and in lead-burning. It has been a practice for the broken surfaces of rolls to be cut away to give room for the new metal. The whole roll is then heated and hottest possible metal run into the intervening space, with suitable headers to allow of escaping gases. I have seen very successful jobs made under these circumstances, and the system is obviously applicable to many other cases.

In the wiping of lead joints for water services we have an example of semi-fusion welding, for, as is well known, the metal used, invariably a mixture containing a high percentage of tin—lead 33 and tin 67—is always in the plastic state during the operation. Great skill is shown by the workman who frequently makes his own metal, not only in so adjusting the addition of the tin that he can tell by its appearance whether he is right or wrong, but also in his use of it, because the heat at which he applies it has to be adapted to the work in hand, and judgment must be further exercised in seeing that the successive layers he applies are really melted or crystallized on to the preceding chilled ones without any "cold shutting." This process of wiping a joint looks very simple, but undoubtedly it requires a great deal of experience and observation for its successful practice, and many branches of plumbing in which the various pieces of lead are joined show a very high order of technical and manipulative skill. On the other hand, I am told by good practical men that if they had their choice there are many cases where they would not wipe the joints. Thus, if a union or cock has to be fixed in a lead pipe, the pipe can be coned or socketed and tinned inside, and if the union or cock to be fixed is also tinned and driven in the pipe, and tinman's solder with extra tin be melted in the annular space with a soldering-iron and finished with a blowpipe, a perfectly satisfactory join results. I think that this is so is obvious, as the bursting strength is clearly greater at such a point than that of the pipe itself. It is also obvious that the bursting strength of most of the wiped joints is unnecessarily greater than that of the pipe on which they are made, and so expensive metal is correspondingly wasted. Two ends of lead pipe may be joined perfectly by fitting one into the other and tinning both surfaces and using solder, as above mentioned. Such joints, however, are not recognized in England by public authorities, though I have often seen them, with variations of detail, on the Continent. Thus I have seen a tinned brass tube inserted in the two ends and the whole soldered up—this makes a very neat and cheap job.

History of Autogenous Fusion

The application of autogenous welding by acetylene hydrogen, benzol, petrol or other hydrocarbon vapor to commercial purposes has extended enormously during the past few years, and constructions and work are now possible by the use of such methods which could not be carried out by any other means, thus repair work of ferrous and non-ferrous metals is now done in every town of importance and tubes of all sizes are made on a very large scale. For branch pipe construction the process is quite unrivaled. For high-pressure steam-pipes the joints after screwing are often welded up, and metal vessels instead of being made with folded joints are now made with the blowpipe more cheaply and far more efficiently. **Lead burning forms an excellent practice for acetylene welding, as it is fusion welding in the simplest form. It is usually carried out with hydrogen and air, and if the workman can make a good joint with and without a stick of lead it is a very easy step for him to advance to making one of aluminum or steel, or any metal.** Lead burning, which at that time seems to have been also known as "autogenous soldering," was first introduced about 1833 by Mr. Mallet, although the invention was also claimed by Professor Daniel, of King's College, and Mr. Thomas Spencer, of Liverpool, read a paper "On the Theory and Practice of Soldering Metals," before the Liverpool Polytechnic Society in 1840, in which he also claimed the discovery of the process. The advantages of such soldering were at once appreciated, especially for chemical works. The objections to ordinary tinman's solder were the great local action set up by varied metals used; and further, the contraction and expansion of the solder under the influence of heat is different to that of the lead which it joins, and so leaks are much more likely to develop.

Fletcher, of Warrington, was the first to introduce autogenous welding. This was in 1888, but he had no commercial success, partly on account of the low heating power of the oxygen and coal gas which he employed, and, secondly, on account of the poor quality of the oxygen at his disposal. Further, the blowpipe used was very imperfect; there was great difficulty in maintaining a uniformly reducing flame. The first practical success with fusion welding was obtained by the late Felix Jottrand, of the Oxyhydric Company of Brussels, who also introduced the first commercially successful application of oxygen for the opposite purpose, namely, the cutting of iron with oxygen, a process also previously demonstrated by Fletcher.

Jottrand's success was undoubtedly due to the fact that the gas employed by him was made by the electrolysis of water, and so was of high quality, and his blowpipe, though complicated, was very efficient. It is still a disputed point whether under some conditions his method with oxyhydrogen is not better than oxyacetylene. In either case it is important that the oxygen used be considerably less than the theoretical amount required, in order that although only a lower flame temperature is available the flame will always be reduced in character. **Benzol, petrol and other hydrocarbons have been recently used in place of hydrogen and acetylene for autogenous welding, and their use would under certain conditions have advantages.**

In practice I have found that a proportion of four volumes of acetylene to five of oxygen gives much better results than the theoretical two volumes of acetylene to five of oxygen. So important is this detail that blowpipes are now generally constructed to consistently maintain a reducing flame. Such a blowpipe is that of the Drager-Greishiem. In this blowpipe the automatic reducing valves on the cylinders are fitted with gauges, which instead of being graduated to pressure are marked with the thickness of the material to be welded—all, therefore, that is necessary is for the workman to adjust the springs on both regulators, so that both gases indicate the same thickness. A simple mechanical mixer is arranged on the blowpipe, making the whole apparatus very practical and convenient.

A characteristic of the oxyacetylene flame is that it indicates the correct mixture, for when the acetylene is in excess a small green cap appears over the inner cone of the flame. On reducing the oxygen there is a point at which the cap disappears. The right mixture is just at this point, and the effect is so distinct that when working with acetylene the workman has no excuse for not getting the right proportion.

If temperature were the only consideration, the oxy-acetylene process would be used in all cases in the working of thin metal, but its use requires much greater skill than the lower heat of the oxy-hydrogen flame. Then again, when a fixed acetylene generator is not available, the risk and danger of a portable generator is considerable, and in such cases for oxy-acetylene welding "dissolved" acetylene only should be used. On the other hand, this is very expensive, and the apparatus is heavy, and it therefore follows that the oxy-hydrogen method with its complete portability is very often to be preferred, because hydrogen can be obtained in the usual bottles, and thus forms very convenient plant.

In welding metals other than iron, not only the melting point but the heat conductivity of the metal must be considered. Thus copper with its high conductivity and its low melting point can hardly be worked with the oxy-hydrogen flame. Indeed, for the same section as iron it requires a much more powerful oxy-acetylene flame. Brass, bronze, and indeed any metal, may be autogenously welded, and many require much less care than that for aluminum.

The conditions of success which apply to all welding with acetylene or other hydrocarbons are: (1) the use of pure gases; (2) the use of a metal rod of approximately the same composition as that of the work to be joined; (3) the thorough fusion of the inside surfaces before the additional metal is applied; (4) cleanliness of the parts, and when desirable the use of suitable dioxidizing and fluxing powders, such as charcoal and borax, and lastly, the use of a blowpipe capable of complete control in respect to size of flame and proportion of mixture. With extended experience in the autogenous joining of non-ferrous metals, it is to be expected that this method will replace ordinary brazing where quality of work is of the first importance.

Welding of Alloy Steel Described

It should be noticed that in consequence of the highly local heating action of acetylene, contraction strains are likely to be set up, which may be more serious than those occasioned when the whole work is heated and welded up in the smith's fire in the ordinary way. In the case of cast iron, it is very desirable that such strains should be avoided by making the weld first and then reheating the mass as much as possible, and cooling slowly. With respect to steel, it has been repeatedly shown that an acetylene or electric weld should not be hammered while the weld is being made. It is well known that cracks are likely to be made by hammering the metal at a black heat, a temperature occurring quite close to the point of fusion. The work, therefore, should be allowed to cool slowly and then raised to a high temperature in the ordinary way and not by the blowpipe; the weld can in this way be much improved both in shape and strength. A good fusion weld very seldom breaks at the point of welding—indicating, therefore, that this point is stronger than the neighboring metal. I believe this is the explanation of the paradoxical effect noticed with fusion welding, that thick sections never give as high a tensile strength as thin. I have figures showing this.

Thus .167 inch 3 per cent. nickel steel strips gave 97 per cent. strength, 1.25 inch gave 90 per cent., while 1 inch bars broke at 60 per cent. to 70 per cent., with the fracture clear of the weld every time. Again, welded .5 inch copper rods drawn down to .375 inch in the ordinary way gave regularly 95 to 97 per cent. as compared with the original drawn rod.

There is an interesting series of processes for the autogenous joining of metals, most of which are patented, which depend on the reducing power of aluminium. **Anyone who has seen the application of the Goldschmidt or**

Thermit process to the joining of the ends of tram-rails can hardly fail to be struck by its extreme beauty and simplicity. We have here a small steel foundry not much larger than a silk hat, from which the metal pours in a perfectly liquid state.

As showing the great heat obtainable when aluminium powder is used for welding, it may be mentioned that if a wrought iron plate 1 inch thick is placed under the crucible, the liquid metal when tapped will burn a hole straight through it, leaving a fairly smooth edge. Experiments show that the heat of the molten metal approaches 3,000 degrees Centigrade, the temperature of a Siemens furnace being about 1,600 degrees Centigrade.

It is very probable that in point of strength most Thermit welds are superior to those electrically made, because the volume of heat is greater if not more intense, and, again, there is less risk of the original surfaces being burnt or oxidized. The Thermit metal can also be adjusted to carry reducing media, which would quite eliminate any oxidizing influences.

A third system of autogenous welding is the electric, of which two methods are in use—namely, arc welding and resistance welding.

Arc welding is applied for repairing breakages and filling up flaws in castings, while resistance welding is rapidly being adopted for the working up of metal articles, and it is common to find electric plant in operation for sheet-iron working. Two forms of machines are on the market for this purpose, one known as the Spot-welding Machine, and another for Butt-welding. In the spot-welding machine the sheets are joined at spots instead of rivets, hence the name. The electrodes are shaped in accordance with the work to be done, and are put onto the work by pressure effected by a foot-lever, and the current, which is automatically switched on at low potential, welds the parts together at that point. After removing the foot-lever the work can be moved along for welding at a new point.

The entire process is so rapid that an unskilled workman is able to make 1,000 welds per hour on plain sheets, while in the same time an experienced hand could hardly put together a quarter as many rivets. The up-and-down movement of the upper electrode may be performed automatically by means of a motor electrically worked. The electrode then falls and rises at regular adjustable intervals, and the workman only has to move the pieces of work.

This machine may also be applied on water-tight welding. In this case the travel of the work takes place slowly, so that the points of welding lie close together, forming an unbroken seam. The edges of the sheets are completely softened, and are pressed together seamlessly. Similarly, when the sheets are not too thick, and irregular shaped sections do not have to be dealt with, the spot-welding machine makes a very satisfactory weld. Thus wheel rims for cycles and motor-cars can be joined perfectly by its means, while the advantage of this system for welding handles on covers, or for welding rings on cooking utensils, etc., are conspicuous. In the same way half-stampings, such as kettle spouts, make up to a very satisfactory job with seamless welding.

Spot-welding is coming into very extensive use for the manufacture of kettles, buckets and similar articles in which the surface is required to be joined only in parts.

In the case of kettles intended for enamelling the old form of riveting occasioned difficulties when the goods were enamelled, because the edges of the rivets and the edges of the sheet refused to take the enamel, or in such thin layers as to interfere with the appearance of the finished work. The difficulty has been avoided and riveting rendered unnecessary by fusing the parts which were formerly riveted by means of the electric arc. The two surfaces are fused together at the point at which the arc is applied, and the enamel can then be run on without any difficulty.

Again, in the manufacture of gas-stoves, where it is desirous to have a layer of air between two sheets in order to economize heat, spaced depressions are made by means of a blunt punch on the sheets, and the sheets put back to back. On applying the arc to the depressions the apices of the latter are fused together, after which the sheet or sheets are enamelled in the ordinary way.

The same process is applied to other goods in order to avoid riveting, and one other advantage is the one of greater permanency in point of mechanical strength, where the goods are alternately heated and cooled. Under this condition of heating and cooling, rivets were often becoming loose, and so occasioned trouble. Galvanized work can be spot-welded. The zinc volatizes off, leaving the iron exposed at the point where the dies come in contact with the metal.

The acting electrodes can be made into various shapes to suit special work. Thus, one can be made circular, freely movable on its axis, while the upper one may be formed of a circular piece of copper swung by a lever. Such electrodes are useful for welding short seams, such as triangular spouts of coffee pots, etc. As the pressure put upon the material is very high, it will be understood that there is hardly any difference in strength between the welded portions and the unwelded material.

Rubber and Carbon Dioxide

A GERMAN chemist, F. Steinitzer, has investigated the absorption of carbon dioxide by rubber and the passage of the gas through rubber membranes, from the standpoint of its use for the inflation of pneumatic tires. He finds that various qualities of rubber used for the purpose show different absorptive powers toward the gas, varying from about 25 cubic centimeters in the case of a heavily loaded gray inner-tube rubber, to 131 cubic centimeters in the case of a best red Para rubber per 100 grams of rubber. The samples were exposed in an atmosphere of dry carbon dioxide at a pressure of 1 kilogram to 1.5 kilogram per square centimeter for periods of from 5 to 8 days for the various tests referred to. Certain of the samples, notably the purer ones, became more or less tacky on absorbing carbon dioxide, and a decrease in tensile strength of from 12.6 to 27.5 per cent. was sustained. In the diffusion tests, the area of the test-piece was 22.3 square centimeters, and the pressure of the carbon dioxide on the high-pressure side 1 kilogram per square centimeter. Some time passed before diffusion began, after which its rate showed only a slight diminution in 10 days. The rate of diffusion increases with higher temperatures, being with sample No. 4 at 10 degrees, 15 degrees and 20 degrees, 0.00200 cubic centimeters, 0.00229 cubic centimeters and 0.00266 cubic centimeters respectively per square centimeter per hour. A solution of 10 to 15 parts of glycerine and 20 parts of glue in 100 parts of water is recommended for producing a thorough gastight coating on the inner surfaces of the tubes.—*Engineering*, Sept. 6.

Heat and Platinum Metals

IN the Proceedings of the Royal Society for 1912, Sir William Crookes gives the results of experiments suggested by his experience with an electric resistance furnace. He found in this apparatus, which consisted of a close helix of platinum strip around a porcelain tube, that the strip thinned and ultimately melted, and on the porcelain tube at the pont of rupture a deposit always occurred, which was found to consist of microscopic hexagonal crystals of platinum. He was thus led to examine the volatility of platinum and the allied metals at temperatures below their melting-points. The metal samples were heated in the electric furnace to 1300 degrees Centigrade for successive periods of 2 hours, when the loss of weight was found to be approximately proportional to the length of time of the heating.

After exposures to 1,300 degrees Centigrade, the platinum had not sensibly changed its appearance, the palladium gradually lost its smoothness and became crystalline with a *moiré* appearance, the iridium showed the same change in a higher degree, while the rhodium slightly darkened, but did not become crystalline. The ruthenium plate, which is very noteworthy for its high volatility, became dull black and was coated with oxide. With iridium, the amount of loss for equal periods of heating at temperatures between 1,100 degrees and 1,400 degrees Centigrade increased proportionally with the rise of temperature. With palladium the loss of weight was more rapid in the earlier stages and the blistered appearance of the metal indicated the escape of occluded gas.—*Engineering*, Sept. 6.

Lengthening the Wheelbase; Novel Valve Action Suggested; Why Five Cylinders Are Not Used; To Add Clutch to Ford Car; Changing Magneto and Camshaft to Chain Drive; A Tempory Spring Clip

Wants to Lengthen Wheelbase

EDITOR THE AUTOMOBILE:—I have a 1911 Regal Roadster which is 100-inch wheelbase and I want to make it 118-inch. The motor is 3 3-4 bore and 4 1-2 stroke. Kindly let me know how much additional power it will require.

Fitchburg, Mass. J. D. G.

—Your motor will have sufficient power to operate the car with the additional wheelbase. The change is not recommended, however, as it will be very expensive if done well, and if it is not done well will weaken your car to a considerable extent. Radical changes in a chassis which has been designed with the special intention of making the parts fit together in one harmonious whole should be avoided.

Running with Dead Cylinder

Editor THE AUTOMOBILE:—If in a four-cylinder four-cycle engine running at about 250 or 300 revolutions per minute with one cylinder disconnected, the petcock to that cylinder were opened, would it affect the speed of the engine, and, if so, would it increase or decrease the speed?

New York City, N. Y. L. E. HOWE.

—If the petcock were opened the speed would probably be decreased. This is true for the following reason. The opening of a petcock is so restricted that the cylinder on its upstroke would have to work against a large degree of compression due to the fact that the air could not escape through the opening rapidly enough. Were this compression maintained as it would be if the petcock were closed, the piston would be assisted on its downward stroke by the expansion of the air compressed on the upstroke. Instead of being aided, however, by the air the latter will have escaped to a large degree through the open petcock during the time the piston was near top dead center and going through the slowest part of the stroke. The result is that on the down stroke the piston will have to pull against a partial vacuum which will further retard its progress.

Wants Parts for the B.L.M. Car

Editor THE AUTOMOBILE:—Could you inform me where I can get parts for a B. L. M. runabout or who took over the stock of that company after they went out of business?

The office of this company was in Brooklyn and the car was made by three men by the name of Breese, Lawrence and Moulten. As far as I can find out this car was made abroad and assembled here. The car I have is the same as those that were entered in the Vanderbilt Cup Race held about 4 or 5 years ago.

Woodmere, L. I., N. Y. Q. F. DISHER.

—This concern went out of business and no one took over the stock or parts. P. H. Gill & Sons, 2 Lorraine street, Brooklyn, made a number of the parts for this car, however, and they may be able to assist you. The motor and several parts were made in Europe as you supposed and then assembled in this country.

Suggests Novel Valve Action

Editor THE AUTOMOBILE:—I have designed a valve action which is new and which I think would be silent as well as of long life. The method of actuating the valves is shown in the accompanying sketch, Fig. 1. It consists of a worm-driven transverse shaft upon which are located a series of eccentrics which are used for driving the rocker arms communicating motion to the valves.

On the end of the crankshaft is located a worm A which engages with the gear B, mounted above it. The gear B is mounted at the center of the transverse shaft C, and is keyed to the latter. As will be seen, the shaft C rotates in two long sleeve bearings and terminates with two cams or eccentrics at either end. The eccentrics D, E. F and G then operate the inlet and exhaust valves, as shown on the left side of the illustration. The eccentric T is connected in such a manner to R that the latter is free to oscillate and at the same time to communicate a reciprocating motion to the shaft S. Through the flexible connection M the bell crank lever O is actuated, moving the rocker arms L which in turn lift the push rods Q. The valve return is secured by the valve springs in the same manner as is customary when cams are used.

Philadelphia, Pa. J. M. WHITE.

Experience with Five Cylinders

Editor THE AUTOMOBILE:—For the benefit of some of your readers who wonder why five-cylinder engines are not used more extensively, I would like to tell of my experience with them and some reasons why they are not more popular.

A few years ago I had occasion to couple together five single cylinders and install in a cruiser. They were all mounted on a heavy cast-iron subbase with thin cranks set at a difference of 72 degrees. The forward cylinder retained its original balance wheel, the other being discarded. After installation I found that it was much superior to a four but in the same way that the four is superior to the three. I cannot say that it even equaled the six in any way whatever. (I am referring to four-cycle motors only.) It is true that in the five each explosion overlaps the next, but not sufficiently to produce the same constant torque that is produced by the six. The impulses in the six are numerous enough so that one does not finish its work before another has taken place and the piston on which it is acting is in a position to do its best, but in the five each piston arrives at the end of its useful stroke before the next one has taken a position where it can do much more than turn the balance wheel. For example, we will assume that we have a five-cylinder motor coupled to its maximum load, without a balance wheel, and we will create an explosion in a cylinder that has its crank enough past center (100) so that it could act. That explosion would turn the crankshaft 150 degrees where it would stop unless another explosion takes place to keep it moving. Now when the first crank passed the 144-degree mark another explosion will occur, but the second crank will not arrive at the 10-degree mark before the first one had lost its power, therefore it would not carry its load. In the six, however, on account of the impulses being only 120 degrees apart the load would be carried very easily, all other conditions being the same. The above figures, although not exact, illustrate a true condition. I think this proves that the five cannot equal the six for continuous torque.

There are other reasons why they are not more popular and I will mention the most important. The expense of manufacturing the crankshaft. When one stops to consider that the crankshaft is a pretty expensive unit and that two sizes can be turned out in the same time that one five can be turned out, he will not wonder why five-cylinder motors are not used.

For the benefit of those who might not understand why the six crankshaft is less expensive I will state that it has but three offsets on account of the cranks being paired together, while the five has five and cannot have any less.

Portland, Me. GROVER C. RICHARDS.

Wants Governor for Cadillac

Editor THE AUTOMOBILE:—Do you know of any governor that would be suitable for a one-cylinder Cadillac?

Niagara Falls, N. Y. R. N. PATTISON.

—An ordinary centrifugal governor could be used on a motor of this kind. Any competent machine shop can install one and the cost would be small. The governor could operate the throttle or it could be attached to the ignition and the motor governed by the hit-and-miss principle. That is to say, when the speed of the motor increases beyond what is required, the ignition is either switched off or short circuited so that there will be no explosion until the motor slows down again. The latter method is a little more expensive as to fuel because the charge is drawn in and exhausted without being burnt.

Lightness Lengthens Car's Life

Editor THE AUTOMOBILE:—Which is of longer life—conditions in both cases being the same, a roadster or a touring car, the chassis in either case being the same? Is not a roadster more economical in every respect, as regards upkeep, than a touring car? What is the most satisfactory arrangement of four forward speeds for country use?

Plattsburg, Mo. M. W. BOHART.

—Everything else being the same a car of lighter weight costs less to keep it up because the tires are not worn as quickly. A man who keeps a roadster and a touring car will find that at the end of year the touring car has cost him more because the expenses included in entertainment will have amounted to considerable more. Should it be necessary to carry three or more people, however, a touring car is necessary. There are many occasions where the owner of a roadster will be unable to accommodate guests whom he desires to take with him on a ride but as far as the expenses of running, such as fuel consumption, etc., are concerned, where the chassis are the same there will be no perceptible difference.

This is a question which has been provocative of lengthy discussion among very prominent engineers. You are referred to THE AUTOMOBILE of July 18, in which practice on this point was fully discussed. In specific answer to your question, however, it may be stated that the following ratios have given satisfaction:

Table No. 1

Speed	Trans. ratios	Ratios—engine to wheels
4	.86—1	3.01
3	1—1	3.5
2	1.76—1	6.16
1	3.4 —1	11.90
R	4.6 —1	16.10

Table No. 2

Speed	Trans. ratios	Ratios—engine to wheels
4	1—1	3.5
3	1.29—1	4.51
2	2.1 —1	7.35
1	3.76—1	13.16
R	4.57—1	15.99

The ratios given in table 2 are recommended because it will be seen that, when it is necessary to change from fourth to third, a speed is obtained which enables the car to go over the hill at a fairly good rate. The second in this is almost between the first and second of the others; consequently, if the car is fitted with a good clutch, the operation for all ordinary driving resolves itself down to a three-speed job (as the second can be used for starting on the level), leaving the extremely low first and reverse for emergency.

On Mounting of Ball Thrust

Editor THE AUTOMOBILE:—In your answer to J. J. Lessing, relating to mounting of ball thrust bearings in motor car clutch, in the issue of November 14 I perceived with some degree of interest the illustration, Fig. 2, showing a ball bearing in place, which you have, no doubt, intended to show your correspondent as a typical construction. The bearing shown is a single row type of the conventional annular pattern and merely supports the end of the shaft that telescopes into the hub of the clutch driving member. Bearings of this type are not suitable to re-

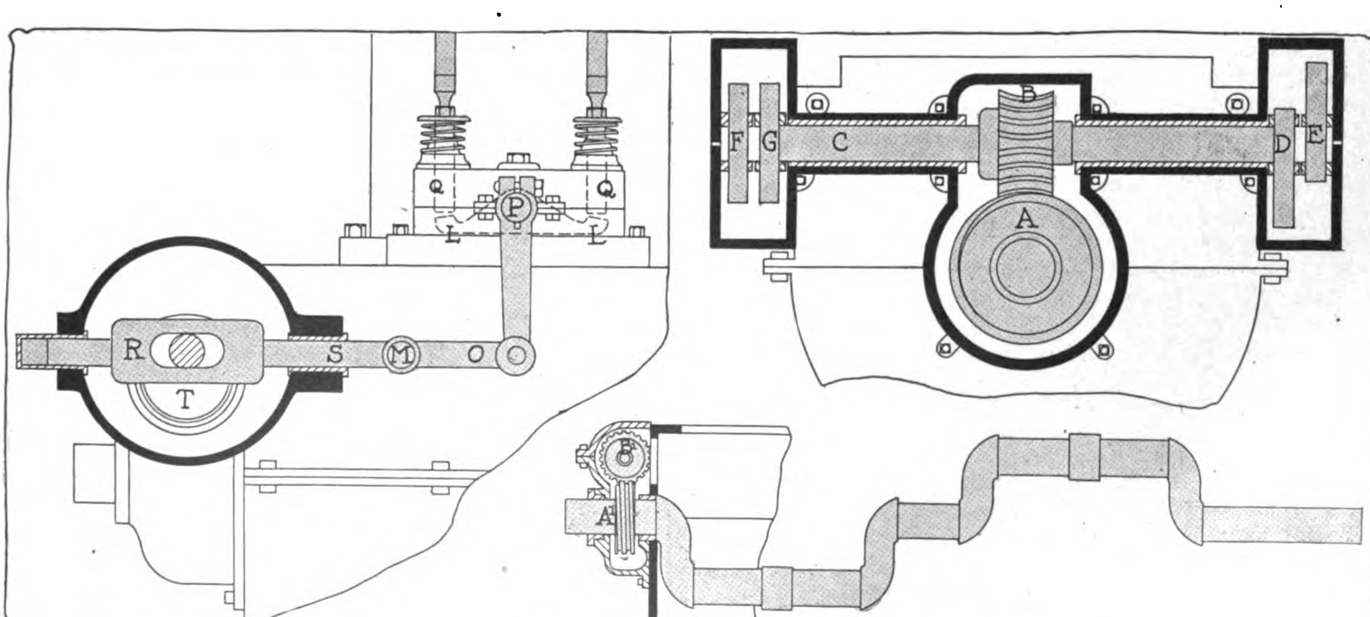

Fig. 1—Worm-driven valve action designed to silence motor. Three views are shown, end, rear and front

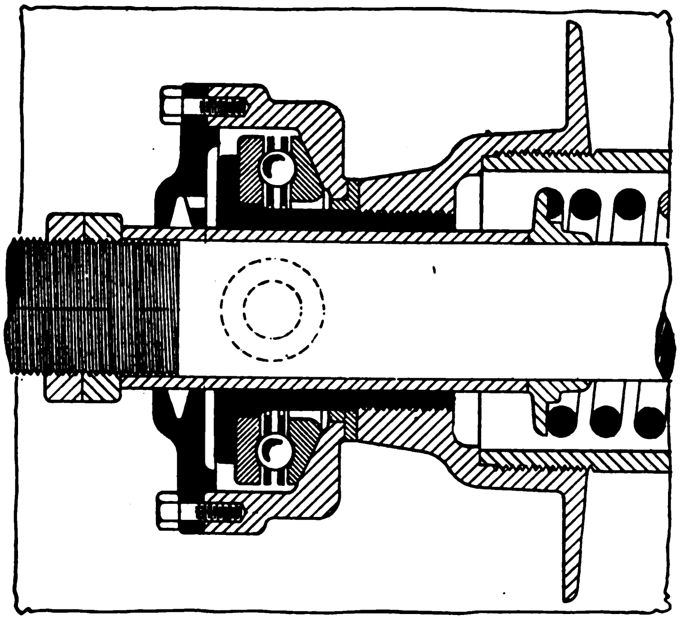

Fig. 2—Mounting of ball thrust on clutch explained below

sist end thrust greater than 25 per cent. of their radial load capacity, so it is difficult to understand how this bearing performs any other function than to support the end of the telescope shaft. No exception can be taken to the explanatory matter, but the illustration is misleading. In order to assist in making this matter clear, I am sending herewith illustration of a typical clutch and gearset assembly, showing clearly the application of a ball thrust bearing as ordinarily mounted. The clutch spring is usually installed so the thrust, when driving, will be self-contained; that is, the pressure of the spring does not exert any thrust against parts not turning with it.

In Fig. 5 you will note that the driving disks C are carried by a member E driven by the engine, while the driven disks revolve with a special member F keyed to the telescopic shaft and extending to the spring thrust abutment screwed on the extension. The clutch actuating spring is mounted outside of this extension sleeve as indicated. When the disks of the clutch are locked together by spring pressure, the spring thrust exerted directly against the abutment at one end, and the pressure member at the other is self-contained, because the parts are virtually locked together and revolve as a single unit. The spring presses against the disks, these in turn against the back plate, forming part of the member carrying the screwed on spring abutment. The ball thrust bearing G shown is under absolutely no thrust load when clutch is driving shafts of gearset. If it is desired to release the clutch, the clutch throw out yoke bears against the radax or cup and cone type thrust bearing outer race, then this member transfers the pressure (opposed to that of the spring) through the medium of the balls and inner race mounted on clutch spring enclosing annulus. This member is drawn back when the pressure applied exceeds that of the spring and as the spring is compressed, its pressure and consequently the degree of frictional adhesion between the disks becomes less until the driving contact is broken. It will be evident, therefore, that the ball thrust bearing is used only when clutch is released. The bearing for telescoping shaft is, therefore, subjected to very little, if any, end thrust.

In practically all clutch designs, the only time the ball thrust bearing is in use is when clutch spring pressure is relieved to break driving contact between clutch members.

Bristol, Conn. VICTOR W. PAGE.

Want Four-Speed Light Car

Editor THE AUTOMOBILE:—I wish to thank you for the stand you take regarding the introduction in this country of lightweight, small horsepower, flexible cars with four-speed gearbox equipped with wire wheels. I have wished to buy a new car for some time past along these lines, but so far have not found a single domestic manufacturer who makes a car along the above lines, and the price of a foreign car with the duty added is too expensive. I sincerely hope that before a great length of time that this sort of car will be produced, as there is already a great demand for it and I feel sure that there would be a ready sale. In the small town in which I live on Long Island I have several friends who would buy a car of this nature.

In case you know of any domestic manufacturer who is contemplating the manufacture of a car along these lines I would consider it a favor if you would furnish me with his name and address.

New York City. W. H. FALLS.

Wants to Add Clutch to Ford

Editor THE AUTOMOBILE:—I have a Ford model S roadster. I cannot keep the grease in the planetary transmission. I have tried almost every grease on the market. At present I am using Dixon's fiber grease. It certainly reduces the noise somewhat, but it slowly, but surely, works out. Would it be possible to put a positive clutch or a clutch that could be engaged gradually on the transmission in the place marked on Fig. 3 at A, so that the high could stay in while on neutral and just a few seconds before starting pull out the high, engage the proposed clutch and then again shove in the high. The object of this clutch is to eliminate noise while on neutral. Complication of control is no objection.

St. Louis, Mo. TRANSMISSION.

—You are running with a gearset which has become worn out. This accounts for the noisy action. It would be cheaper and more satisfactory to replace the worn parts than to attempt to fit the clutch, which would necessitate so many changes that it would be impractical. In order to prevent the working out of the grease you could have an aluminum casting made, such as is used in the model T. This would rest on the side members and would allow the gearset to set down within the bottom casting. Over the top of this would fit a coverplate that would enclose the gearset with an oil-tight gasket. In order that the fiber drums will not slip when covered with grease and cause lost motion, they should be removed and asbestos fabric substituted. The castings can be easily and cheaply made by your local foundry.

Changing to Chain Drive

Editor THE AUTOMOBILE:—Is it feasible to change the magneto and camshaft drive in a four-cylinder motor to the chain drive?

Hasbrouck Heights, N. J. F. W. HOBBS.

—This could be readily done, but it is doubted if the results would be as satisfactory as would be the case if you replaced your worn gears with others which fitted closely. The use of the chain entails the necessity of having a chain adjustment unless the center distances are exactly as required. This, taken together

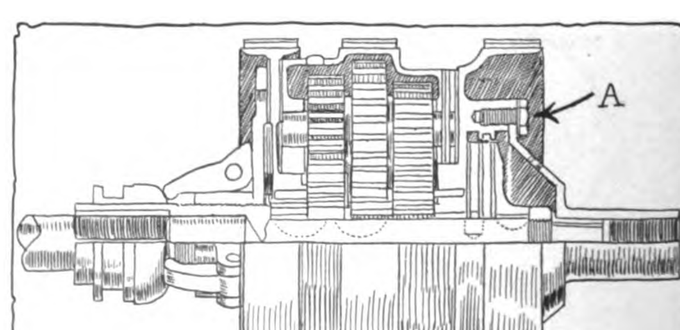

Fig. 3—Showing proposed location of clutch on Ford gearset

with the fact that the wheels would have to be replaced by others suited for the chains and that these wheels are wider by 100 per cent. in many cases, may render it impractical. On the other hand, however, it may be that the chain drive is well adapted to your car. The following data is necessary in determining if the chain drive would be applicable, and if so, what would be the size chain required:

1. Brake horsepower of motor at 1,000 revolutions per minute.
2. Maximum revolutions of engine.
3. Number of cylinders.
4. Pressure in pounds to lift each valve spring.
5. Will pump, magneto or fan be driven from crankshaft?
6. Ratio of motor to camshaft speed.
7. Ratio of motor to magneto speed.
8. Ratio of motor to pump speed.
9. Minimum bore of pinion to fit crankshaft.
10. Pressure per square foot of exhaust gas at opening of exhaust valve.
11. Diameter of valve head.
12. Weight of valve and tappet.
13. Profile of cam.
14. Details of any dimensions that are limited by conditions.
15. Rough sketch showing the disposition of the drives and the desired working center to be attached.

The above is a copy of the form sent out by the Coventry Chain Company, of England, which is represented in America by the Sarco Engineering Company, 116 Broad street, New York City.

Percentage of Slip of Wheels

Editor THE AUTOMOBILE:—Why are not speedometers attached to the rear wheels of a car? Is there no way of eliminating the complicated mechanism necessary for attaching the speedometer to the front wheels? What is the cause of the comparative inaccuracy of a speedometer? That is, why will one instrument measure a certain distance over a certain stretch of ground while another, mounted on a different car, will give a distance which is at distinct variance with the results given in the first case?

New Rochelle, N. Y. OSCAR WHEELEN.

—The mounting of the speedometer upon the rear wheel would be the cause of great inaccuracies because the rear whels have more slip than the front wheels and because the differential action would interfere to some extent. Henry Souther, former president of the Society of Automobile Engineers, compiled some useful information on the slip of rear wheels at the Brooklands track in England. The following tabulation prepared by him after carefully investigating this question throws considerable light on the matter:

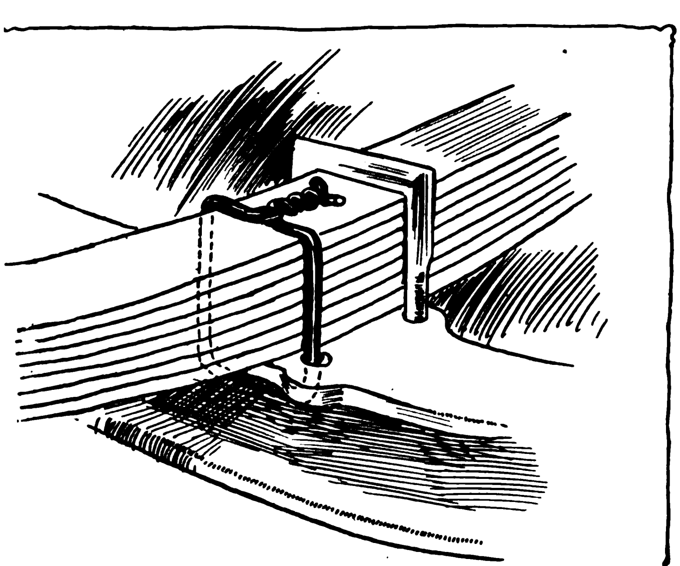

Fig. 4—Temporary repair replacing missing spring clip

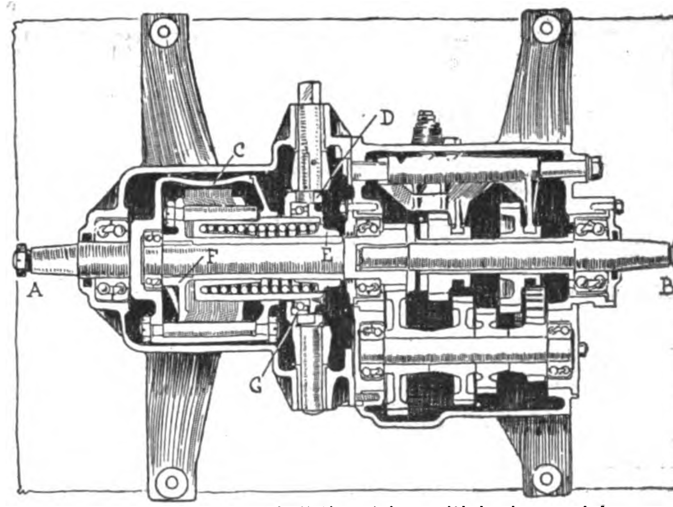

Fig. 5—Mounting of ball thrust in multiple-disk clutch

Percentage slip	Speed
.3	40 miles per hour
.6	50 miles per hour
1.1	60 miles per hour
1.8	70 miles per hour
3.7	80 miles per hour
5.4	90 miles per hour

It will be seen from the above table that traction is better at low speeds than at high. The tests were made with plain round tread tires. It was noted that the inner wheels slipped a little more than the inner while rounding a curve at speed, because the centrifugal force tended to remove the weight from this side. The Knox Automobile Company has mounted the speedometer upon the drive shaft for next year. This does away with the complicated mounting and enables the makers to place the speedometer where they desire without having any difficulties with the flexible shafting. The difference in two instruments may be due to many causes, such as inherent inaccuracies, improper mesh of gearing, rough roads, etc.

Tires Stick to Rims

Editor THE AUTOMOBILE:—I am going to put up my car for the winter season and I would like to know how to prevent an annoying trouble that caused me a large amount of distasteful work with emery paper this spring. The rims became so rusty that I could not put tires upon them until the rust had been removed. I live in a very damp climate and as the air is somewhat salty its action on metal is very rapid.

Freeport, N. Y. B. T. HAFF.

—The best way to avoid this trouble is to clean your rims thoroughly with kerosene when you remove the tires for the winter, and then to paint the rims with graphite paint.

Made Temporary Spring Clip

Editor THE AUTOMOBILE:—The other day, after I had accidentally discovered that one of my front spring clips was missing, I had a temporary repair suggested to me by a member of our party which proved of considerable value. In my tool kit I have always made a practice of carrying some stout pieces of wire for emergency. We took one of these pieces of wire, about 14 inches in length, and bent it into a U shape. This was slipped up through the holes used for the missing spring clip, as shown in Fig. 4. The two loose ends of the wire were then loosely twisted together and a strong screwdriver inserted in the loop and used as a tourniquet. By turning up tightly on the screwdriver the wire was brought strongly up against the spring and then bent down. We had a run of about 200 miles over rough country before we arrived home and the repair held excellently. I would advise any automobilist to do this rather than run any distance with a missing clip.

Redesigning the Body

WE are trailing—Europe is leading.

The Englishman with his round-the-world reputation for comfort is to-day setting the pace in automobile body design. It is meet that he should fill this rôle in so far as comfort is concerned, but it is further true that he wears the rôle of leadership in design also.

At last the English designer, who is generally a French importation, has recognized the fact that **body design begins with the radiator and ends with the baggage rack or license light.**

Up to the present the body design started at the dash or ended with the tonneau. There was no harmony between the bonnet and the body. The same radiator or bonnet were used for the runabout, the berline, the coupé or the seven-passenger tourist. The same straight-line bonnet and radiator lines were used whether the body were a stream-line creation, a straight-line design, a combination curve and convex or a torpedo model. To-day nearly all American makers are still doing this, so are the majority of the European builders, but the end is in sight.

Art is entering into body building.

Because a man wears a cuff on his outing trousers does not call for such decorations on his evening suit. The red necktie may be correct in the business office, but it is, nevertheless, unpardonable at the banquet table. So with the bonnet on the car. It is an integral portion thereof and must be considered a part of the body design.

The days are passing when a maker will refuse to alter the bonnet shape or radiator design solely because he looks upon it as a recognized trade-mark or name-plate. While there is a stock-in-trade value in respect there is also a deterioration in appearance.

To date many body designs have been but compromises. The body builder, a graduate of the horse-carriage trade and hopelessly ignorant of the automobile chassis, set boldly at a task, a task which began at the dash and worked back to the rear end. He was not even permitted to make the bonnet. The buyer who purchased a chassis also purchased a bonnet, and while the carriage builder was given carte blanche in body lines he could not even alter the bead work of the bonnet or a line on the dash. The resulting body was a natural sequence—a two-part affair, one the radiator, bonnet and dash, the other the body proper.

The recent Olympia has demonstrated that the renaissance has begun. The designer has included the bonnet and dash in the body proper. Before him is no easy task. He has started valiantly, however. To accomplish the task has consumed space in some models. Space is needed to imperceptibly mold the body into the dash and bonnet. But even here economy is at hand, a gasoline tank has been taken from under the front seat or from the rear of the chassis. This leaves more available baggage space, gives shorter gasoline connections and makes gravity feed feasible. While doing all of these things it offers a solution of the hollow dash, a dash which forms a pleasing transition between bonnet and body.

But the end is not yet! **The top will have to be improved.** As to form, there is little certainty. It may be that when the top is folded it will disappear within a space in rear of the tonneau upholstery, so that a leather flap will hide it and give a completed finished appearance. Some day the spare tire and spare wheel problem will be solved. These will be concealed within the body, or, in other words, the body will be designed to contain them. More adequate baggage space must be provided.

Europe for 1913 is experiencing a return to the four-passenger body, as compared with the pronounced tendencies to five-passenger designs of the last 2 or 3 years. The onward march of the small motor has partially caused this, but it is also true that the four-passenger size has a broad field and is more comfortable for a load of four than a five-passenger style.

Many foreign countries are leading us in the vital question of weight reduction. American cars are to-day too heavy for their general design and also their requirements. A leading maker recently stated that carrying the two demountable rims with tires in rear of the tonneau was equivalent to two 200-pound passengers in the tonneau. This is an enormous load, carried as it is well in the rear of the axle where its side-slip, as well as its vertical whip, is maximum. Such a load racks the chassis, makes steering more difficult and wears out rear tires.

Manufacturing Success Points to Concentration

George W. Bennett's Address Before the N. A. A. M., Outlining the Subject at Greater Length Than Appeared Last Week Brings Out New Thought on Close Relationship of the Maker with Men Who Distribute His Product

THE trend of success in the automobile industry today is unquestionably pointed toward concentration, and concentration is not possible where the product is divided into several models. **Little doubt exists in my mind but that eventually the marked successes of the automobile business will lie in specializing, each plant making that which best fits its demand, and making that model in the quantities to which its place in the automobile market entitles it.**

To make several models in a factory which is equipped to make not more than one satisfactorily, necessarily restricts the output of that plant and divides the energies of its engineers, its operatives and its selling force into several small channels, all of them considerably below par in efficiency because of such division.

Experience has shown that there exists a market for a certain number of cars at a certain price, each of a different class, and each appealing to a different grade of buyer. The growth of the industry shows that the most prominent manufacturers have realized this and are catering to the class they can best supply.

I believe this development will become more marked and that in a very few years each factory will limit its product to one model, with perhaps several styles of bodies interchangeable on the chassis.

One Chassis Type Not Always Possible

It may not always be possible for one manufacturer to profitably restrict himself to one chassis, but it will be possible, if more than one is considered necessary, to make a large number of the parts interchangeable, and only in this event would the production of two models be warranted or likely to be successful. We are all familiar with the most striking success in the industry, who for the past 3 or 4 years has made practically no changes in his chassis, who makes his various styles of bodies fit that one chassis, and has limited himself to that one model, producing it in immense quantities.

I do not believe his success can be duplicated, since the existing product practically fills the market for automobiles of that price. Nor is it possible that any other manufacturer can compete with him, as the model in question is the culmination of many years' experience in building that particular type, and of daily and prolonged thought to economy in its manufacture.

I am fairly well satisfied there is no other equally large market available, the demands for cars of higher price being necessarily limited by the decreasing number of individuals whose incomes are sufficient to justify the greater expenditure. This decrease becomes more marked as the prices go up. It will take a cleverer statistician than I am to compute the possible markets along this line, although it must be clear to those who have given the matter any thought that the quantity market for each class of car is limited to the possessors of sufficiently large incomes to make the purchase. It is a point, however, that should be seriously considered by every manufacturer today. **Obviously there are more manufacturers of automobiles than there are classes of purchasers, and the process of elimination, which it must be admitted is working fairly fast, must in the near future determine that ratio.**

Furthermore, the subject of subsequent service is involved so much that where more than one model is built adequate service to the user is difficult, and consequently seldom satisfactory, and without that satisfaction complete success is impossible.

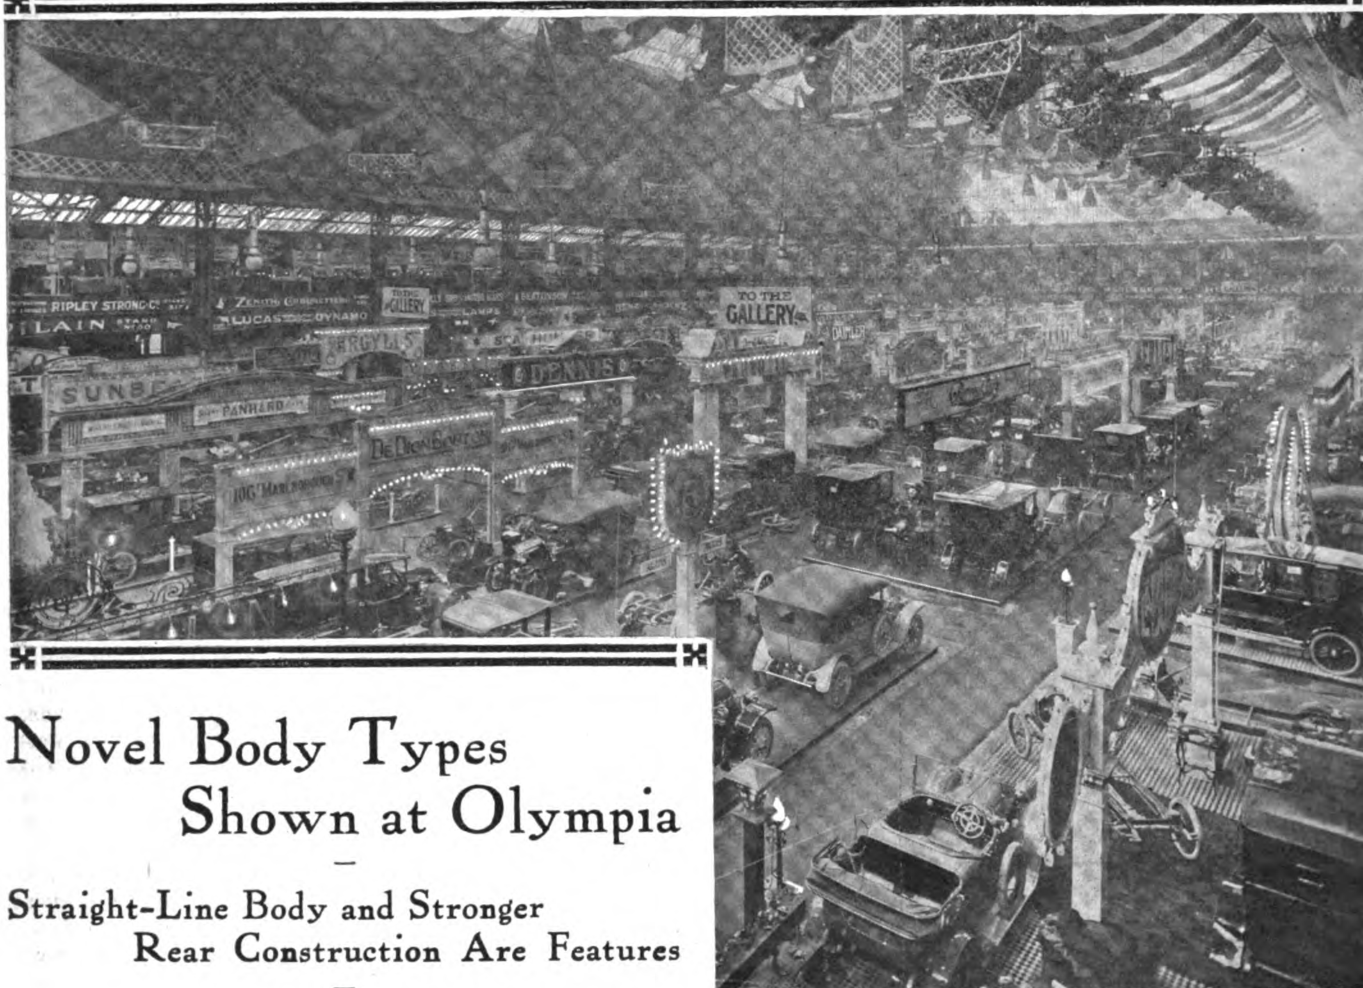
In view of the endeavor of the pioneer manufacturer to supply his dealer with a complete line, and admitting in the majority of cases his necessity, and further having in mind my remarks as to concentration by manufacturers, I think the same result will be accomplished by a different method. Dealers who are limited by their agreements with manufacturers to sell only the one line, are necessarily restricted in their markets and in their earnings. This course invites competition among dealers, adds to their number many who are irresponsible, and the final result is that but few of them at the end of the year show any profit. With the idea of concentration carried out by manufacturers, it would necessarily follow along to the dealers, and would result in each dealer having a line no two models of which would be competitive in price, or similar in general detail, and which would enable him to cater to more than one of his markets.

The manufacturer cannot be successful unless his dealers are successful, and their interests are so interwoven as to be identical and absolutely dependent each upon the other. I venture to assert that this phase will receive considerably more thought in the future than it has in the past.

It would be expecting rather too much to hope that we shall be able so to arrange the production of automobiles that all of us will prosper and each occupy his own niche in the industry. I believe, however, that this association, which comprises most of the manufacturers of automobiles in this country, is in a better position to accomplish approximately this than any other agency that can be imagined. We have no factions, no politics, no patents, and, so far as I know—and I speak with some authority as to the executive committee—every individual comprising the working end of the association is working for its benefit and for the harmonious operations of the industry.

Association Another Form of Concentration

It would be anticipating the millennium to believe that any of us—myself included—is going to bare all his inner thought to public gaze or even to that of his fellow members, but I am certain that the closer we keep together, the oftener we have these meetings, and the more freely we interchange ideas, the better it is going to be for all of us. We are all fairly experienced men of the world, and while, as I say, none of us is likely to speak with absolute frankness, I believe the lines of thought disseminated at such meetings as this, properly analyzed and considered—as they are likely to be by those hearing them—will have the effect of unconsciously shaping our plans to the desired end, so that eventually we shall all be moving along the line of least resistance and accomplishing that which we deem success.



Novel Body Types Shown at Olympia

Straight-Line Body and Stronger Rear Construction Are Features

By J. S. Critchley

Fig. 1—Bird's-eye view of Olympia during first week of the show

OLYMPIA continues to show the tendencies of European design as in previous years. Primarily an exhibition of expensive cars, it is only to be expected that luxuriant body work will be exemplified in the cars which are seen here. That this is true will be seen in the brief descriptions of some of the more noted types, given at the end of this article.

Last week THE AUTOMOBILE dwelt at length upon the developments of the motor, clutch, gearset and rear axle construction. Continuing a detailed study of these features before commencing the investigation of the body, some of the types which stand out on account of noteworthy design will be mentioned.

A few of the most important developments should be described, however, apart from the individual description. The worm drive is one of these features.

One of the questions which has not been fully decided in either English or Continental practice is whether the worm should be mounted above or below the gear. There are two reasons for this uncertainty on the part of designers. The first is the fact that when the worm is below the gear, lubrication is easy. The oil being in a pool in the lower half of the housing is generally of sufficient depth to submerge the point of contact between worm and gear teeth. The advantages of this are readily apparent. Wear is reduced to a minimum, the worm is rendered, if possible, even more silent in its action and the length of life of the bearing parts is indefinitely extended.

On the other hand, however, there is the question of road clearance. Foreign practice, while less exacting in this respect than American, still calls for at least a minimum of 7 inches.

Another point which attracts considerable attention is the mounting of torque members and the general distribution of stresses throughout the rear construction. It may be of interest in this connection to refer to Fig. 3, which shows a plan view of the four-cylinder, 15.9-horsepower Arrol-Johnston chassis. As may be seen from this illustration, the side channel frame members are swept in at the rear and firmly joined by a gusset plate which constitutes a horizontal web, thus producing a remarkably rigid structure at this point and one which would be practically impregnable against all ordinary racking strains. The torque tube is still in common use and there is no tendency for its abandonment, although the juncture of the torque tube to the frame and rear axle has been given more attention.

Springs, both in the mounting and shape, seem to be undergoing a process of development. The cantilever type of rear spring is increasing in popularity. The Rolls-Royce Company has changed to a spring of this type. The drive is taken through this spring and in place of the radius and torque rods a large, spherically ended torque and radius rod of circular section inclosing the propeller shaft is fitted. This means a decrease of weight, less expensive work and at the same time an equal amount of strength.

It is well known that in springs of the cantilever type means must be taken to prevent a lateral movement relatively to the rear axle. This is effected in the Rolls-Royce by collars formed on the rollers carrying the ends of the spring. Another interesting point in connection with this spring on the Rolls-Royce car is the provision of a safety stop which prevents the axle from leaving the frame should there be a fracture of the torque tube.

Brakes have not ceased to attract the attention of the designer. Improvements at this point have gone hand in hand with other efinements about the rear end of the chassis. Fig. 9 shows how he back of the Sheffield-Simplex car is constructed. The large ibbed brakes are a prominent feature. The wide face of the rakes will be noted also. This is illustrative of a general increase in brake sizes throughout European practice. With the icrease in body and chassis refinements, especially with the ixurious appointments of the former, an increase of weight as rendered necessary an increase in braking power. This has lso made it necessary to maintain an extraordinary rigidity irough those members which absorb the braking strain. For iis reason we see an increase of the strength of the rear axle ousings, torque members and, where the drive is carried hrough the springs, in the connections of the latter to the rame members.

Another feature for which perhaps the increase in braking ower is responsible is the increase in transverse stiffening members at the rear of the frame. Referring again to Fig. 9, the hannel connections at this point may be noted. The mounting f the gasoline tank between these members, while not really structural feature, is of interest.

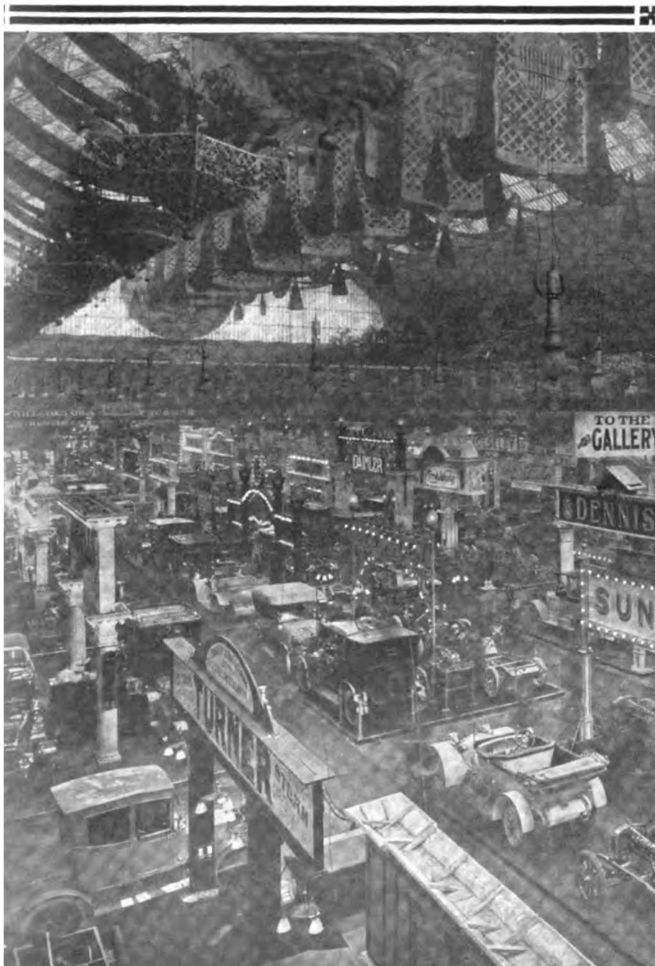
Before leaving the subject of springs, the reversion to the nderslung rear under the Daimler car will be of particular iterest. As shown in Fig. 11, this form of mounting permits f a flat spring when the car is under load. In the illustration ist referred to it will be seen that the spring has a slight curvture. When under the load of the body and passengers this pring will be practically flat and horizontal. The use of the full liptic rear on the Arrol-Johnston should also be noted. It ill be seen in Fig. 5.

A complete gear is being fitted in place of the sector on many f the steering gears. The object of this is to provide for a change of the teeth which are in engagement with the worm as soon as they become worn. It is only necessary to revolve the gear through 90 degrees in order to secure a complete new set of teeth in contact with the worm. In this connection it would appear that the slight increase expense in manufacture was more than equalized by the increased possibilities of compensation for wear.

Before touching on a few mechanical features which were not in last week's article the marked developments in body work should be mentioned. In the higher-priced cars there seems to be no possible luxury that has not been incorporated. The convertible body, as it is understood in America, has not as yet forced its way on the British market. In place of this there is the cabriolet, which can be quickly changed from a town to a touring car. Landaulets, limousines and Berlines are meeting with considerable favor, although they are being modified more or less to follow the whims of fashion. Torpedo touring bodies, such as that shown in Fig. 10, are increasing in popularity. The scuttle dash also prevails to a noticeable extent. Dashboards, in the latest cars, are invisible, the upper end being flush with the straight-line body. Another marked tendency is that shown in Fig. 16, where there is no definite line to mark the junction of the hood and the scuttle dash. Bizarre types of body, while frequently seen at the exhibition, are not turned out in any of the manufacturers' stock models, being merely given as body maker's suggestions.

The bodies illustrated at the end of this article, other than the French diligence coach, are to be found in the regular stock bodies turned out by the car makers. The stripped chassis is disappearing and in its place the complete car is being marketed.

In the Vauxhall car both types of detachable wheel are in use, the wood artillery wheel and a double spoke wire wheel with the Riley locking device fitted. The same driving pegs are employed in each case. To revert to the axle itself, the main casting is steel, into which steel tubes are fitted. It will be seen at once that the entire weight is carried on these last mentioned tubes and not upon the axles, which have to take torsional strains only and are consequently fairly light in section, the diameter being 1 3-8 inches. Each hub is supported upon three ball journal bearings. The centers of the two outer bearings are 5 1-8 inches; the outer bearings have 3-8-inch balls and the inner and larger bearing 7-16-inch balls. At the inner end of each hub a substantial ballthrust bearing is provided, the balls being 7-16 inch in diameter.



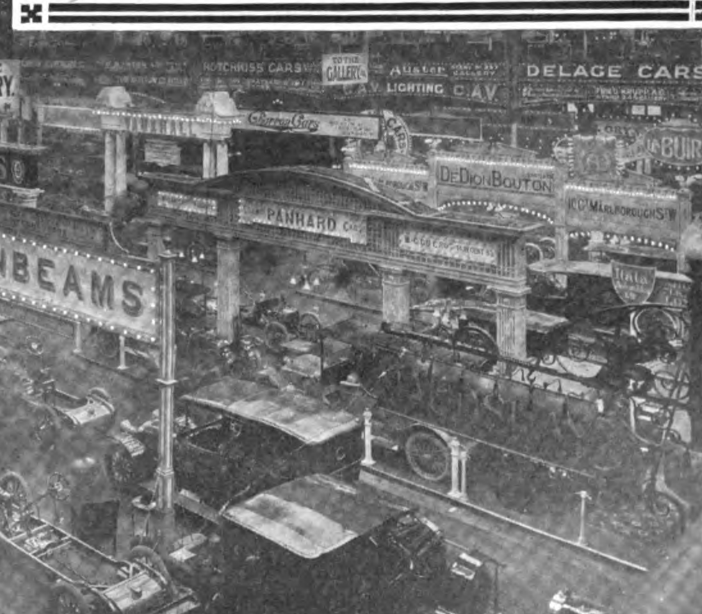


Fig. 2—Looking down one of the aisles of the English section of Olympia before the opening of the show

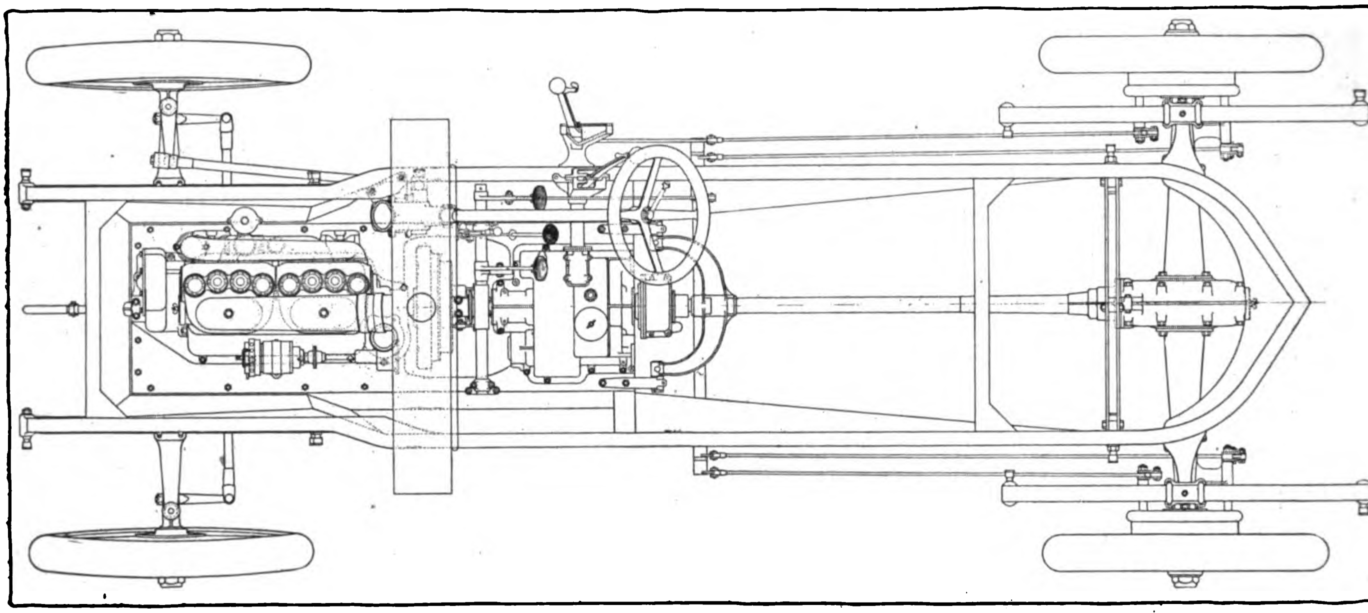

Fig. 3—Plan view of the four-cylinder 15.9 horsepower Arrol-Johnston chassis, showing the unique rear junction of frame side members

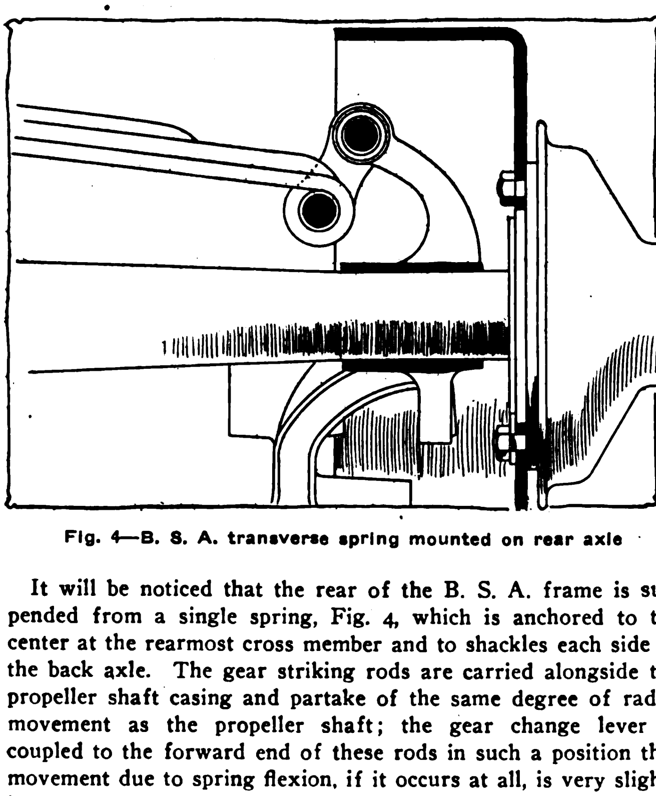

Fig. 4—B. S. A. transverse spring mounted on rear axle

It will be noticed that the rear of the B. S. A. frame is suspended from a single spring, Fig. 4, which is anchored to the center at the rearmost cross member and to shackles each side of the back axle. The gear striking rods are carried alongside the propeller shaft casing and partake of the same degree of radial movement as the propeller shaft; the gear change lever is coupled to the forward end of these rods in such a position that movement due to spring flexion, if it occurs at all, is very slight; in any case it has no effect upon the meshing of the gears within the box. The brackets for holding the back end of the engine are of good, substantial construction, and they can be clearly seen in the plan of chassis.

The chassis presents a very neat and simple appearance, the brake and other rods being all very direct, bell-cranks and such devices being conspicuous by their absence only.

Fig. 6 shows various views of the Belsize worm-driven back axle. The worm is of the parallel type and is situated above the worm wheel. This latter is a little unusual in its form. It has considerable width so that when bolted up in place it forms the outer casing of the differential box, the sides of the box being plain flange pieces with holes drilled to take the differential spur pinion. The construction is a very simple and cheap one, and does not appear to possess any bad points whatever, indeed each one of the parts is comparatively cheap to produce and therefore cheap to replace; there is perhaps a little more metal to the worm wheel than would usually be the case, but this is not a formidable objection.

It will be noticed that the differential spur wheels are cut solid upon the axles, which latter have a diameter of 32 millimeters. This gives a very strong sound job, but in the somewhat unlikely event of a spur tooth breakage it would be necessary to replace the entire shaft with its spur wheel cut upon one end and its other end splined to take the permanent hub. It is no very easy matter to decide how far to carry the once piece system in any design; carried too far it is an undoubted nuisance to the owner, in the case of breakage, and yet on the other hand the absence of any pieces fastened on, knocks out one possible source of trouble. It would seem that the particular piece of design referred to may be classed as good practice and not really objectionable. The greater part of the weight of the road wheels is taken upon the axle tubes, though there is a bending moment in the axle ends as well.

Means are adopted to prevent oil reaching the brake drums, for the screwed in plate that retains the ball journal bearing in position has at its outer diameter a V-shaped edge. Any oil flung from the edge of this when the wheel is revolving passes on to the light steel metal cover shown and cannot well reach the braking surfaces. The brake drums have a diameter of 10 inches and the shoe width is 1 3-8 inches.

The axle is braced by a steel tension stay 7-16 inch in diameter; this is attached beneath the spring seatings and passes under the axle casing. It will be noticed that instead of using a double ball thrust bearing at the back of the worm as is usual practice, single thrust bearings are employed and these are placed outside the journal bearings. Such an arrangement is perhaps conducive to cheapness, but it possesses the objection that if the worm and its shaft become at all heated—as it is quite likely to—the expansion throws an altogether unnecessary load upon the ball thrust. Perhaps the makers allow for this fact by permitting a trifle of end play for the worm shaft; if this is the case the matter must be attended to in the assembling as there is no possibility of after adjustment.

The Wolseley differential case is made of malleable iron and split vertically, being strengthened with an under tension stay. The worm and shaft can be removed without dismounting the axle, and the worm is of steel hardened and polished, with a worm wheel of phosphor bronze. The differential ends of the driving axles are mounted with ball bearings and the thrust provided against by ball thrust washers, and felt pads are employed to retain the oil. The drive is taken through the springs and torque rod is provided, the fore end of which is anchored to a ing mounted link secured to the frame cross stay. All spring nts are as a matter of course fitted with grease cups.

)n the Vauxhall car the lock nut used in connection with the ey wheel is of interest, inasmuch as in place of the usual double k with which it is customary to furnish a detachable wheel, re are in this case to all intents and purposes three locks. Two :he small spring catches in use can be observed in the figure, l over one of them is a pivoted cover or flap, which also serves purpose of a lock. Further details will perhaps be out of ce just here.

:he differential gear is of the strength spur-pinion type and is haps a little stronger in construction than is usual,. for the eels are of good sinze and have a pitch of number 6. The ball rnal bearing that supports the driving axle close against the wn wheel is a strong one and has balls 5-8 inch in diameter. ›se alongside it is a thrust bearing to take the thrust due to bevel drive. The bevel pinion which is one piece with its .ft is exceptionally well supported, as will be seen by an exination of the figure. There are here three journal bearings well as the usual thrust bearing. It would seem that through- the axle the designers have been at great pains to insure that ball bearing shall be overloaded, as not only are the bearings ge but in several cases they are in duplicate. In the whole e there are no less than fifteen ball bearings—a number that uld have been considered extravagant a few years back. The wn and bevel wheels have a pitch of 5 and the teeth are -2 inches wide. When necessary the bevel pinion can be reved by swinging the propeller-shaft clear and removing four s on the front casing. The axle casing is filled with oil ough a filler projecting at the back; the top of the filler uth corresponds with the correct oil level in the axle case, so t it is not possible to pour in more oil than is necessary. The r axle brake drum and the shoes can be seen in the drawing. as they are of fairly usual construction they do not call for special comment.

)n the steering gear a noticeable feature is that the worm ft is supported by roller bearings and it is presumed that substitution of roller bearings for ball bearings gives a ater freedom for the steering; if this is indeed the case then can well approve of the alteration. A complete worm wheel ısed in place of the perhaps more usual sector, and since only ›ve 90 degrees of the wheel comes into use from complete lock one direction to complete lock in the other, the wheel can be fted round a quarter of a circle when worn, thus giving ır separate positions to compensate for wear.

:here is a conveniently placed oil filler on the upper part of steering box, and it is of interest to observe that both the eel and the worm are of phosphor bronze.

Before leaving this very interesting chassis some particulars materials used in the construction of the more important parts l be cited, and it will be seen that the quality of the material could not at the present time well be improved, and this will be clear from a perusal of the table that follows:

Name of part	Materials	Ultimate stress. Tons per sq. in.	Elastic limit. Tons per sq. in.
Crankshaft	Nickel chrome steel	50	40
Gear shafts, propeller shaft and axles	Nickel steel	40	22
Gear wheels	Nickel chrome steel	108	102
Front axles	Mild steel	35	24
Stub axles	Mild steel	35	24
Crankshaft bearings	White metal	..	..
Gudgeon pin bushes and bushes generally	Phosphor bronze	..	..
Crankcase and gearbox	96% aluminum	13	
Cylinders	Hard cast iron	..	..
Levers	Mild steel	28	14
Hubs and brake drums	Mild steel	28	19

A bevel drive is used in the new Star back axle and the bevel shaft is supported by large diameter ball journal bearings placed 2 3-4 inches apart. The bevel pinion shaft has a diameter of 1 3-4 inches and it will be seen that there is a small ball journal bearing immediately behind the pinion so that the shaft is well supported. The width of the bevel teeth is 1 1-4 inches, rather a less width perhaps than is usual, but the wheels are both of good diameter. A bevel type of differential gear is employed, the shaft wheels being mounted upon squares. The axles are 1 1-2 inches diamter and do not take any part in supporting the weight of the vehicle, but serve merely as driving shafts. The wheels are mounted upon large ball bearings on the axle tube ends and a detachable wheel is used.

The design of the axle is throughout compact, but there appears to be some degree of unnecessary weight, more especially in connection with the bearing supporting sleeves which fit into

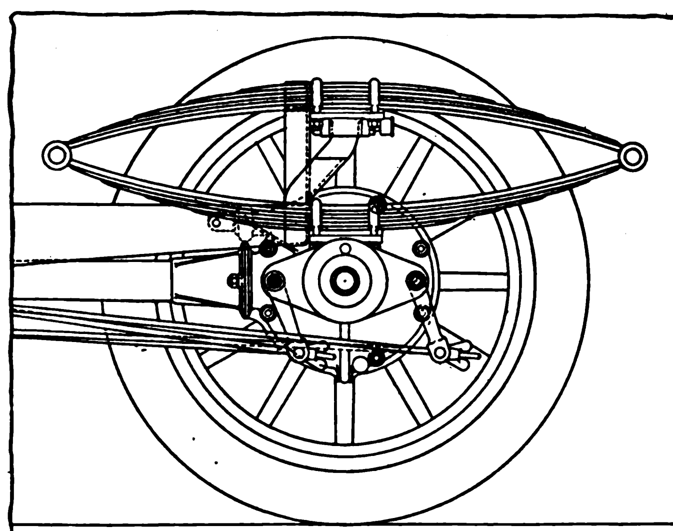

Fig. 5—Arrol-Johnston uses full elliptic rear spring

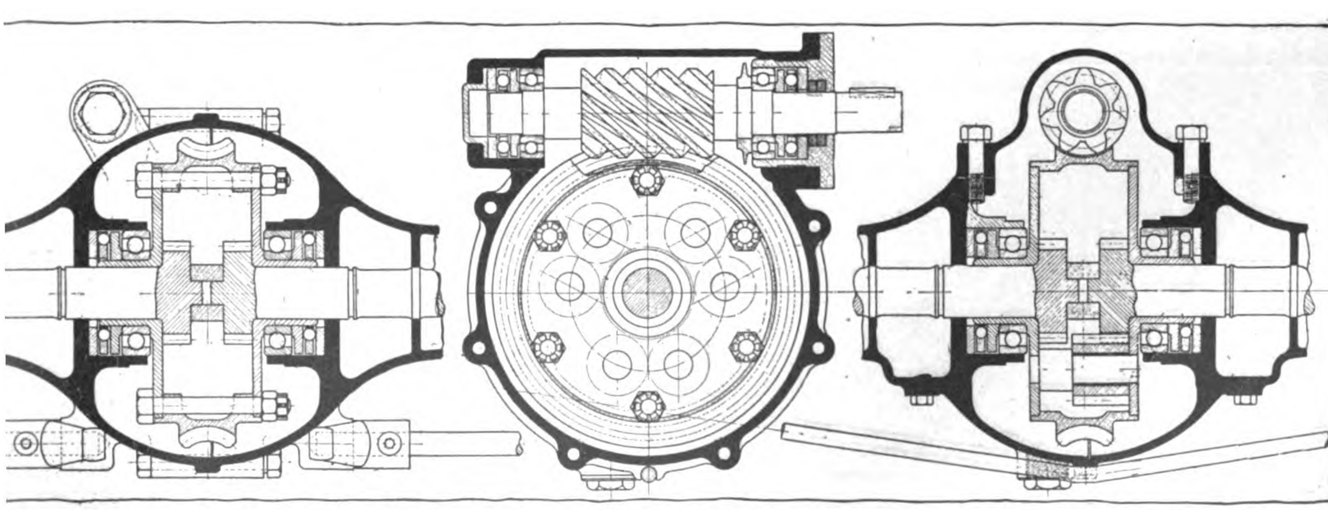

ig. 6—Belsize worm drive, showing ball-bearing mountings for worm and gear. Left and right views show end and center shows side view

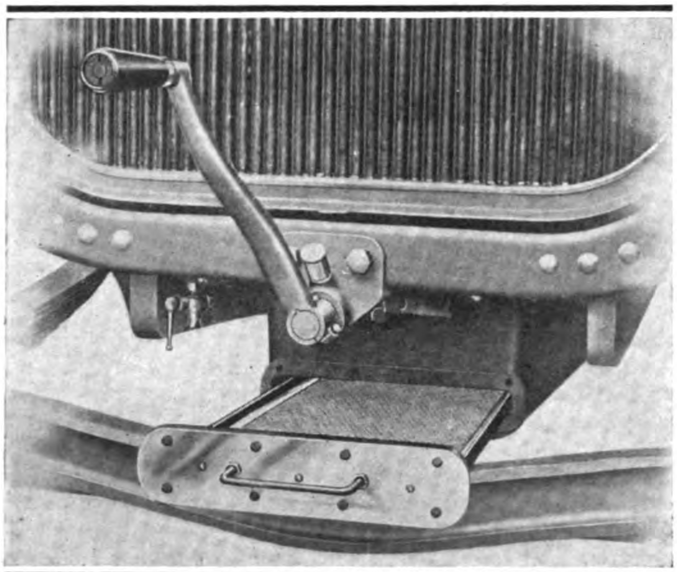

Fig. 7—Removable strainer pan in Vauxhall oiling system

the cast axle tubes. These, it will be noticed, are heavy and might well, one would think, have been made lighter without unduly decreasing strength. The axle tubes themselves, too, are perhaps a little heavy, though when using castings here a good deal of weight is difficult to avoid.

The brake shaft, which is 1 inch in diameter, is well supported by two bearings whose centers are 8 1-2 inches apart and the bearing brackets are strong. The bracket nearest the brake drum nearly always takes the form of a suitably ribbed disk, in some cases slightly dished; thus the chances of a breakage here are not at all considerable.

The Swift rear axle is of the floating type supported on load ball bearings throughout, the bevel pinion being carried on a separate unit bolted to the differential case and can thus be easily dismantled for inspection purposes. The differential case itself is split horizontally, thus insuring oil being retained. The torque of the bevels is taken up by a V torque rod with buffer springs hinging from the forward cross member of the main frame. The frame itself is of pressed steel inswept at front, upswept at rear, the inner folds of the side members being extended and pressed to rectangular section and thus forming an under frame for supporting the engine and gearbox. This is an expensive job but undoubtedly tends to ensure perfect rigidity and alignment. The steering is of the worm and nut type, the box itself being attached to the main frame by a circular flange, provision being made for a varying rake of steering post to be fitted. The springs are semi-elliptical front with three-quarter elliptical rear, the latter taking their support on the spring

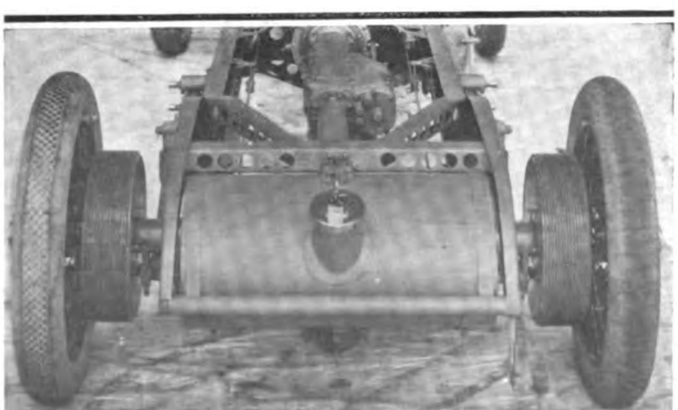

Fig. 9—Tank and brakes on 30-horsepower Sheffield-Simplex

block which swivels on a suitable bearing on the axle sleeve. Detachable road wheels, 760 x 90 millimeters, are fitted. Wheelbase, 9 feet, wheeltrack, 4 feet 3 inches.

The width of the teeth in the Briton bevel rear axle is 38 millimeters and the pinion is cut solid upon its shaft. Here again there is the before-referred-to combination of bearings for the forward end of the pinion shaft is supported in a phosphor bronze bush while at the after end there is a ball journal bearing. This latter bearing appears to be very necessary since the pinion overhangs its journal bearing somewhat owing to the interposition of a ball thrust bearing. The differential gear has bevel wheels and the driving wheels are mounted upon squares upon the axles. At their outer ends the axles have squares to

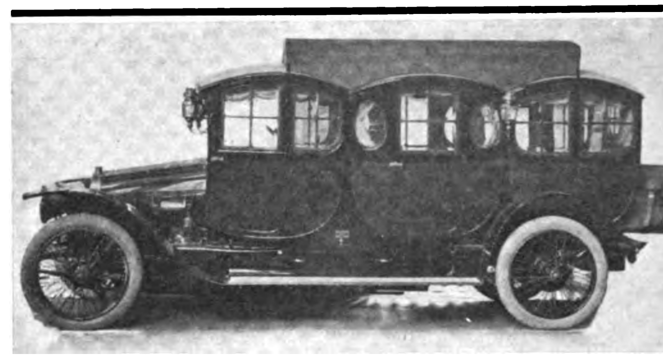

Fig. 8—Gregoire diligence coach seen at Olympia show

drive the wheel hubs and it will be at once noticed that the driving axles have to take the weight of the vehicle as well as the torque. The overhang of wheel to ball journal bearing has been reduced as much as possible in order to keep down the load on the bearing and prevent any possibility of a bending action being set up; thus the distance from center of wheel spoke to center of ball bearing is less than 2 inches.

The chief alterations of the Rolls-Royce cars for 1913 will be the employment of the cantilever type of rear springs and also the employment in place of radius and torque rods of a large spherically ended torque and radius rod of tubular section enclosing the propeller shaft.

Referring to the inverted springs, they are pivotally attached to the side members of the main frame by means of blocks each of which is attached to its spring at the point of maximum bending moment. These blocks engage with pins or shafts integral with or rigidly attached to brackets mounted on the side member of the main frame. The latter may be suitably stiffened at this point by cross members or other means. The front end of each of the springs is supported on the side member of the main frame by means of a link which is pivoted to a bracket formed on or attached to the side member of the main frame. The rear end of each of the springs rests on a roller mounted on a pin carried by a hanging bracket formed on or attached to the rear axle casing. Lateral movement of the springs relatively to the rear axle is prevented either by means of collars formed on the ends of the rollers or by causing the springs to engage with the inside faces of the brackets. A safety stop may be provided to prevent the axle from leaving the frame in the event of the tubular member enclosing the propeller shaft, breaking. The tubular member which is rigidly attached to the axle casing and envelops and encloses the propeller shaft is attached at its forward end to the main frame by means of any suitable form of universal joint, a convenient form of which is spherical and bears upon the outside of a hollow ball which is attached to the main frame either by means of trunnions or in any other suitable manner.

The action of this improved suspension is as follows: The axle casing and propeller shaft casing form a rigid transmission unit which is attached at its front end to the main frame of he vehicle by a suitable form of universal joint. This arrangenent together with the lateral rigidity of the inverted springs onstrains the axle to move only in a vertical direction relatively o the frame, said movement being controlled by the vertical esilience of the spring. It further allows either wheel to rise elatively to the other without straining the controlling mechaiism in any way.

Last year the Rolls-Royce Company stiffened up the frame of the chassis by introducing tubular cross members, with a iew to preventing the twisting of the frame and the setting up of strains in the body. This year the frames will be further tiffened up by the employment of tie rods from end to end. Other lines of improvement consist of a brake adjustment of he road wheel brakes which is now effected by finger nuts intead of spanner as heretofore. Louvres have been introduced nto the under-screen so as to carry away the heated air from he engine. Ventilators also have been fitted to the dashboard.

Provision is now made for driving a dynamo for electric lighting by means of a special pulley fixed at the front end of the ear box. The cone clutch has been improved by the use of a pecial fabric lining on the cone in place of leather as formerly sed.

The show indicates more than ever the tendency toward luxriant body work. Fewer chassis are exhibited, and on many of he leading stands, such as Rolls-Royce and Daimler, no chassis re exhibited, but merely completed carriages. The coach work s very magnificent, and the tendency of design of nearly every ype of body is in connection with the stream line order or toredo shape. Carriages of the limousine and landaulet order ke those of the touring types have sweeping scuttles to harmone with the sloping bonnets, and this with their lowness to the round, domed roofs, and sloping extensions adds much to heir elegance. The cabriolets are becoming more popular, due o the ease and quickness with which they can be converted rom entirely closed town carriages into completely open touring cars.

The landaulet type of car is becoming considerably modified. An example of the latest construction of this type is shown in onnection with the Delaunay-Belleville body.

This body is of the limousine landaulet type, and while

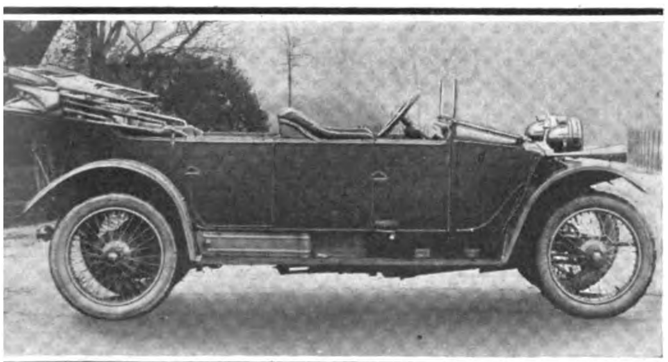

Fig. 10—Lanchester torpedo touring car. Note short bonnet

t has almost the appearance of a limousine it opens out in a imilar manner to the older three-quarter landaulet. Several examples of the latest type in body work are illustrated in onnection with Napier, Rolls-Royce, Delaunay-Belleville, Sheffield-Simplex, Daimler and other well-known makes. A study of the design of these cars illustrates the fashionable lines now prevailing.

The new special Daimler chassis has been designed to supply he demand for a car of the highest possible grade, and no effort has been spared to make it ideally suited for those who desire he best, irrespective of cost. Throughout the design there is no endency toward originality for its own sake; the chief features are on the lines proved best by past experience and every minor

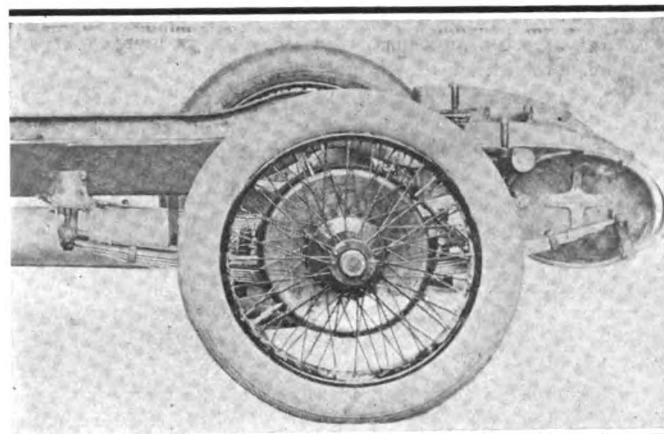

Fig. 11—Daimler gasoline tank swung between rear springs

detail has been perfected for the object for which it is designed.

The chassis has a wheelbase of 11 feet 11 inches, which provides ample accommodation for a body of the largest size. At the same time the steering gear has been so designed that the car can be turned round in a comparatively small circle and hence it is easily handled in traffic. The tread is the standard 4-feet 8.5-inch gauge, and the ground clearance is ample for all requirements, fully 8 inches being available at the lowest point.

Motive power is supplied by a six-cylinder Daimler sleeve valve engine of 101.5 millimeter bore and 140 millimeter stroke. This engine is amply powerful for all work and even in hilly country the car will take full load everywhere on top gear. A high speed average can be maintained without the slightest trouble or inconvenience to the passengers. Various special engine features, such as the offset setting of the cylinders and the arrangement of the carbureter, result in usually good slow running qualities. With full load on board the car will run at a slow walking pace and pick up from this to a speed of 60 miles an hour without any apparent effort or noise.

The transmission components include a leather cone clutch, having special springs beneath the leather to insure smooth starting, a four-speed and reverse gearbox and worm-driven rear axle.

A special feature to which attention may be directed is the withdrawal of the clutch by the side brake so that the clutch shaft and gears may be at rest when the car is standing with the engine running. But, to enable the engine to be used for braking purposes at the same time that the side brake is in operation, there is a second position of the latter lever, which thus has gate control, to secure the desired result.

The springing is a portion of the design which has been very thoroughly tested. The front springs are of the semi-elliptic type, broad and long, fitted with the Daimler swivel shackle at

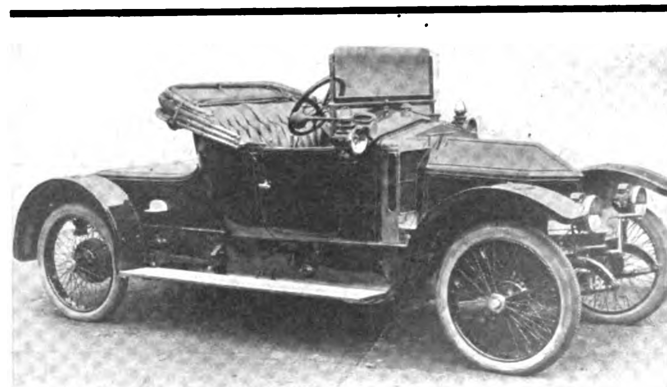

Fig. 12—Deasy two-seated runabout with convertible rear platform

the rear end, to prevent frame distortion. Three-quarter elliptic springs are used at the rear, Fig. 11, and in conjunction with the efficient shock absorbers fitted between the axle and the frame these completely insulate the body from all road shocks.

A high-powered car of this type requires very satisfactory brakes and it will be found that those fitted in the present case are strong enough for all requirements. In addition, they are well supported and easily adjusted, while, in the case of the rear wheel brakes, satisfactory equalizing mechanism is employed.

The Daimler Cranmore is a six-seater landaulet fitted to a 26-horsepower chassis. This body is of the low-built type introduced by the Daimler company, at the last Olympia show, and which has proved so extremely popular during the past year. There is ample room both in front and at the rear for all the passengers, while the seats are broad and thickly cushioned. The coloring is black with fine white lines, and the upholstery is black leather for the front seats, and black morocco with special dark gray cloth and laces inside. The interior decorations are of silver and rosewood.

The Compton six-seater limousine, fitted to a chassis known as the special Daimler, which is fitted to a six-cylinder engine, 101 by 140 millimeters. This carriage is colored gray, with a darker shade for the top quarter. The interior arrangements of this car have been carried out on a luxurious scale.

The Argyll car has a worm-drive back axle. The worm is cylindrical and is mounted over the wheel on a short length of splined shaft. These splined shafts occur frequently in the Argyll chassis and this method of attaching a part of a revolving shaft is undoubtedly a very good one, whether the part in question has to slide or is stationary. Splined shafts are generally considered somewhat expensive and no doubt they require special machinery and well kept cutters for their proper production, but for first class work they form an essential part.

A heavy double ball thrust has a position at the back of the worm as usual and the adjustment for this bearing is a good one, consisting of a nut with holes for turning and a castellated locking cap, the latter being locked in its turn by a steel spring finger piece.

The journal bearings for the worm are 7 inches apart and have balls 9-16 inch in diameter. A bevel type of differential gear is employed, having three planetary wheels. Single ball thrusts occur betwixt the differential casing and the back of the bevels and a small ball thrust collar finds a position where the driving axles would otherwise abut.

The driving axles have a diameter of 1 7-16 inches and are submitted to a torsional strain only, there being no bending action whatever. Once again the spline system is in use in connection with the driving of the permanent hub. The journal bearings of the road wheels are spaced 3 1-4 inches apart and are well protected from road dust by a packing groove. The plate casting which protects the brakes and holds the brake shaft and fulcrum pin has an annular recess cast upon its interior face to

Fig. 13—Austin landaulet with auxiliary chair upholstered to match trimming

catch any oil, and thus to prevent any detrimental lubrication of the braking surfaces.

At the inner end of the axles, outside the ball-thrust bearings, spring held disks are provided to prevent the escape of oil from the axle casing and in addition there are screw stuffing boxes with locked glands, so that even after a long period of time there should be very little loss of oil; thus adequate lubrication of the worm and its wheel is particularly well looked after.

A great amount of thought and consideration has been given to the design of the 38.4-horsepower, six-cylinder Napier royal saloon carriage, by the Cunard Motor & Carriage Company.

The body takes the form of a wholly inclosed car, with a glass division separating the driver's compartment from the main portion, with three entrance doors, and three windows in the body besides those in the doors, a wind-cutting glass screen over a deep scuttle extension of the dashboard and a roof with edges blended into the sides and back of the body.

Throughout the car, the predominant feature is the grace of the curves which harmonize one with the other wherever their outlines meet. The car is low and sleek in appearance, and appeals to one's sense of swiftness and elegance. The height inside, however, is ample for tall persons, and ladies with high hats will find that their convenience has been amply studied and the necessary head-room given.

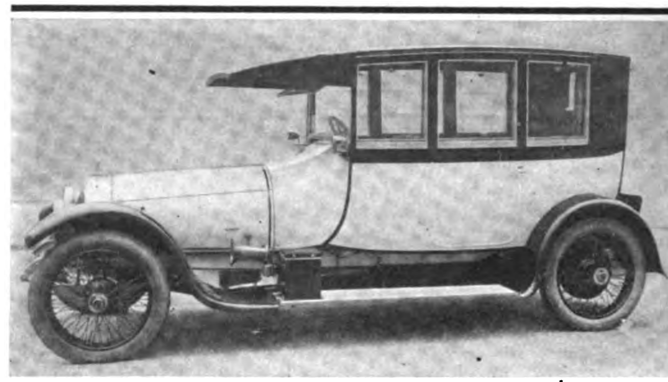

Fig. 14—Exhibition model of 30-horsepower Sheffield-Simplex berline

With regard to details, the four passengers in the rear interior are carried two on the main seat and two on folding seats with back rests, which latter are designed for comfort. Access to this part of the car is by a very wide door on either side. The driver's compartment is entered by a door on the near side and to give easy access to his seat; the passengers' seat is made to tilt up like a theater stall. This method of construction does not interfere in any degree with comfort, and arm rests are provided. The division at back of driver's seat consists of two windows arranged to lower, and at his side the window comprises two pieces of glass divided vertically one to slide over the other. Throughout the car the windows are frameless, of best plate glass, and those arranged to drop have new patent lifters which easily and securely fix them in any desired position and obviate the use of the usually awkward strap.

The windscreen in front of driver, carried on a deep extension rearwards of the dashboard is a V-shaped wind deflecting type which was introduced on the six-cylinder Napier car that gained the Grand Prix award at the Turin Exhibition. It has been improved since, and the rearmost vertical frame brought well back so that nothing now obstructs the line of vision of the driver Each frame of the V contains two glasses, the lower of which is fixed and the upper adjustable outwards to any angle—each window independently of the other.

Aluminum is used almost wholly throughout the construction of this body and every curved panel has been beaten to shape by hand. The decoration of the interior has been carried out to combine utilitarian purposes with artistic effect; inlaid satinwood has therefore been chosen, and the roof, sides, doors nd heelboards are comprised in the scheme. Exquisitely fig-red panels and plain panels with sections set out with the grain t varying angles add to the beauty. The upholstery is in cream ıorocco, and four electric lamps on projecting brackets are fitted ith shades of floral design. Metal interior fittings with their elicate tracery in siiver and dull gilt impart an air of refinement. very point that the most fastitious could demand has been udied, even to regulating the temperature of the interior, and a entilator is fitted in the roof with its opening adjustable at the ill of the occupants by a very ingenious cylinder and piston evice. A Hall flap is also provided to enable the passengers to ommunicate with the driver.

The finish of the exterior is a tasteful shade of cream with lack, the panels and bonnet being in the former color, while ıe roof and wings are black. The combination, notwithstanding s contrast, is particularly pleasing and harmonious.

The chassis has Rudge-Whitworth detachable wire wheels with

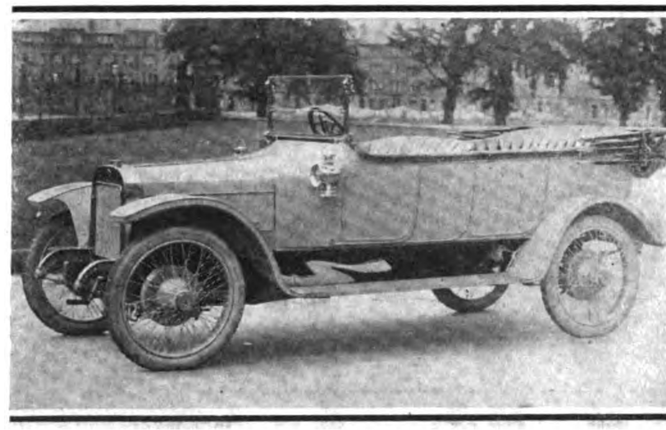

Fig. 16—Argyll 15-30 model made specially for Olympia exhibition

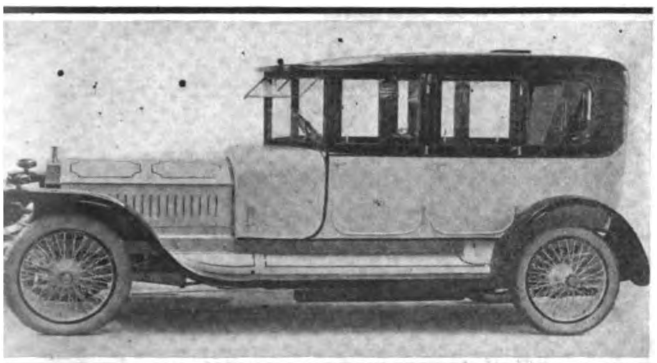

Fig. 15—Special six-cylinder Napier exhibited at Olympia show

95 by 135 millimeter tires all round, and the new wheelbase is ı feet 6 inches.

In the British high-price car the accessories are exceptionally ell taken care of. Electric lighting is fitted to all the makes and rnamental features instead of being treated as extras are fitted s a matter of course and the parts of the car that they are at-ıched to take the fittings in a rigid and substantial manner. his is especially true in the matter of the top. This is generally esigned to swing back of the body, as in Fig. 16.

Figs. 15 and 16 show the clear running boards and side ıembers. Nothing is permitted to mar the elegant appearance f the straight-line body. Tools, tires andother impedimenta are ept away from the body of the car and are placed to the rear of ıe chassis or beneath the passengers' and driver's seats.

Harking Back a Decade

FROM *The Automobile and Motor Review,* November 22, 1902:

The new type of electric delivery wagon being put out by ıe Vehicle Equipment Company carries 1 ton of freight and av-rages about 50 miles a day. This extraordinary mileage is ac-omplished by recharging the partially discharged batteries dur-ıg the noon hour.

Applicants for space at the Madison Square Garden Show are ill swamping the managers of that exhibition. The allotments ave been made and save for a change here and there, the late pplicants will have small chance to secure space. The show will e held January 17-24. The annual banquet of the N. A. A. M. ill be held January 21.

The worm has apparently turned. Theodore Havemeyer, an ıtomobile owner of Brooklyn, has instituted suit for damages gainst Charles Hart, a contractor, alleging that through the efendant's negligence in leaving an excavation unprotected, into hich Havemeyer's car plunged, injuring four persons. Litigation f the past has been practically unanimously against the automo-bile owner and the outcome of the present suit will be watched with interest.

Alexandre Ular has discovered, in an article published by *L'Auto Velo,* of Paris, that the Chinese had mechanical vehicles 1,600 years ago and used them extensively. In northern Mon-golia he found two huge locomotives employed in drawing gold ore over the highways. The wheels of these machines are 7.5 feet in diameter. Mr. Ular proposes to make the trip from Pekin to Paris with a machine similar to these locomotives, which the reader is made to infer are relics of the antique automobilism of the Celestial Empire.

If any proofs be needed that the present limit of speed for motor vehicles is far below all reasonable requirements of safety, it may be found in the record of the Reliability Run, in which, counting the convoying vehicles as well as those compet-ing, upward of 100 cars traveled a distance of 500 miles each without an accident to an outsider, much less to the riders.

No hill-climbing contest of real importance has yet been held in this country. The nearest approach to a national event was the climb of Nelson Hill last year, but blockades of the road were so frequent during the running that the results were deprived of comparative value.—Editorial.

Eagle Rock Hill in New Jersey has been selected as the course for the Thanksgiving Day hill climb, November 27. The hill is 1 1-8 miles and has an average grade of 14 1-2 per cent. There are a number of severe bends in the road. The early entries for the contest indicate that all the events will be well filled.

The Automobile Club of America now has 392 members, ac-cording to the annual report submitted by Secretary Samuel M. Butler.

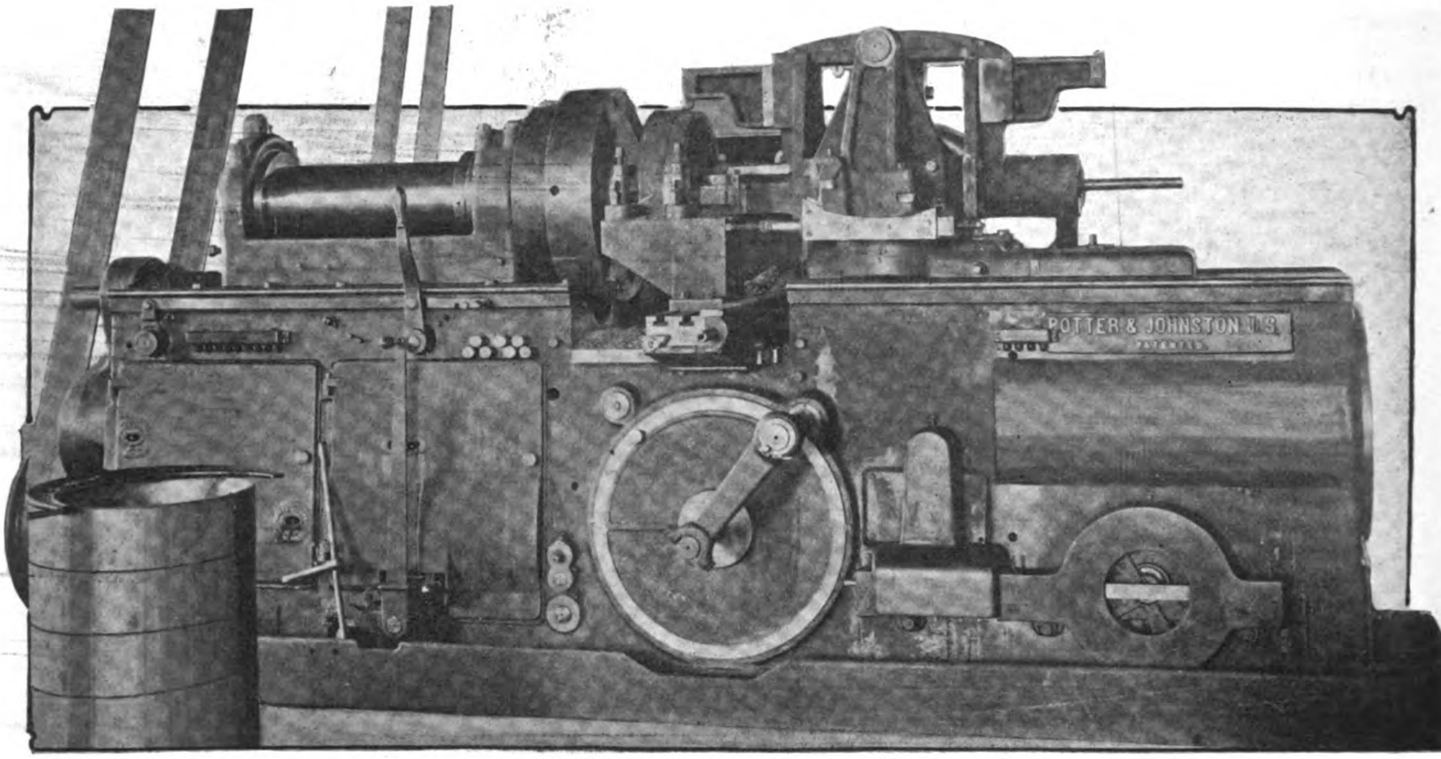
Henry Fournier has lowered W. K. Vanderbilt's world's record for the flying kilometer and Augieres has set a new mark for the flying mile. The cars used in each case by the record breakers were of Mors manufacture as was also that of Vanderbilt. Fournier's time for the kilometer was 29 1-5 seconds and that of Augieres for the mile was 46 seconds flat.

According to the estimates compiled by Winthrop E. Scar-ritt, president of the A. A. A., the 1903 production of automo-biles in America will be 35,000. He predicts that there will be 50,000 buyers who will try to supply their requirements. He does not say how the overplus of 15,000 customers are going to ride next year.

Barney Oldfield, who set fast marks for the mile and 5-mile distances in a Ford-Cooper racer at Detroit, never drove a car until 10 days before the race trials.

Directors of the A. A. A. have decided to give their support to the project of promoting a national highway from coast to coast. General Nelson A. Miles proposed the road and several bills to secure national co-operation have been presented to Con-gress. The A. A. A. has determined that none of the bills in-corporates exactly the right features and is preparing to draught a bill on its own initiative.

Factory Miscellany



Special Automatic lathe used in the factory of the Moline Automobile Company, East Moline, Ill., for turning down flywheels

MOLINE flywheels are turned down by the special machine shown above after they have been roughly cast. This is an automatic machine in that it requires no one to turn a turret or to reset the machine after every operation. It is only necessary to feed the unfinished flywheels. It takes one man only to do the work, and his duties are merely to keep the machine supplied with work and to see that the belting and lubrication of the machine are as they should be. It requires 1 hour and 10 minutes for the machine to finish one casting. This consists of grooving out of the oil ring and turning out the seating for the cone clutch. During the course of a working day the machine can turn out nine finished flywheels and the time required in changing over from the finished job to the commencement of the next is only 4 minutes. The work of changing consists in taking out the finished flywheel by simply pushing back on a lever, slipping in the new wheel and again starting the machine.

MOLINE FACTORIES BUSY—Moline, Ill., manufacturers of automobiles, Moline, Velie and Midland, will be up and doing during the coming year. During the past season 3182 machines have been built and marketed by the three local factories. Plans for 1913 are for the building of 5,900 cars, nearly twice the output of last year. During the coming year 3,500 Velie automobiles and trucks are to be put on the market, while 1,400 Midland cars are planned for next year. The Moline Automobile Company built 782 machines this year and will raise the mark to 1,000 during 1913.

Large Addition Necessary—The Belle City Brass & Iron Company, of Racine, Wis., has commenced work on a large addition which is made necessary by the tremendous rush of orders. All departments are working over capacity and overtime.

Doubles Capacity—The Racine File Company, Racine, Wis., has doubled its capacity and changed its factory drive to electricity throughout. Much new equipment has been added. The company does a large business with motor car and parts manufacturers.

Robinson Adds Truck—The Robinson Motor Truck Company, Minneapolis, Minn., has added a new model to its line called the Minneapolis, a four-cycle truck. The company will continue to make the Gopher, a two-cycle car. The new machine runs in 1 1-2, 2 and 3-ton capacities. The list price of the chassis is $2,500.

Buick Plant Inspected—With Michigan's new compensation law in effect, the Buick Motor Company, Flint, Mich., is setting about the organization of a vigilance committee to make the rounds of the entire factory with the idea of recommending changes which will end to reduce the danger of accident to a minimum.

Chatham Accessory Factory—Work will be started soon on the transformation of the Nellis building, Main street, Chatham, N. Y., from a garage into a factory for the manufacture of automobile parts. A third story may be added or the present building may be raised and a three-story brick structure erected in its place.

Building in Toledo—The last of five new buildings to be erected on Madison avenue, Toledo, O., for the sale of automobiles and automobile accessories is that of the Six Realty Company, which will extend the Madison avenue Auto Row westward. The five structures are either under way at the present time or are in the hands of architects.

Kelsey's Memphis Plant—The Kelsey Wheel Company, Detroit, Mich., will operate at Memphis, Tenn., a plant to manufacture automobile spokes and rims. Two buildings have already been completed of the three proposed. The plant will have a daily capacity of 25,000 spokes and 4,000 rims and machinery will be installed to cost $12,000.

Takes Over Patent Rights—The Columbus Auto Parts Company, Columbus, Ohio, a new corporation recently chartered with a capital of $25,000 has taken over the patent rights and plant of the Columbus Auto Parts & Machine Company. The concern now occupies a large new plant at Russell and Fourth streets, which contains 16,000 square feet of floor space. The company manufactures the Columbus Friction windshield exclusively and is very busy on large contracts to supply automobile factories. C. J. Krag is president; C. M. Klages, vice-president, and R. E. Klages, secretary-treasurer.

Moon Making Improvements—The Moon Motor Car Com-
any, St. Louis, Mo., plans to make further improvements
› its plant.

Ford's $250,000 Plant—The Ford Motor Car Company, De-
oit, Mich., has given a contract for a six-story assembling
ant, in Minneapolis, Minn., to cost $250,000.

Rex Plant in Nashville—The Rex Chemical Company, New-
ort, Ky., will establish a factory in Nashville, Tenn. The
ompany will manufacture polish for automobiles.

Rubber Company's Addition—Work was recently started
ı a two-story brick and steel factory addition, for the Port-
ge Rubber Company, Barberton, O., to cost $15,000.

New Plant at Dunkirk—Work was started recently on the
iagara Gasoline Motor Company's Building, Dunkirk, N. Y.
he building will be under cover before winter sets in.

Marathon Doubles Capacity—The Marathon Motor Com-
ıny, Nashville, Tenn., which has been making thirty cars a
eek, is to install equipment which will double the capacity
its factory.

Larger Tire Plant—The Automobile Tire Repair and Sup-
y Company, Philadelphia, Pa., has leased the building for-
erly occupied by the Auto Equipment Company in that
ty, and is using it for a vulcanizing and solid tire plant.

Purchases Atlas Works—J. W. Lyons, who recently pur-
ıased the Atlas Engine Works and a plant covering 65 acres
Indianapolis, Ind., has engaged J. Haltenberger, an auto-
obile engineer, to keep pace with the foreign experiments,
hich are being carried on by C. K. Knight at Coventry, Eng.

Firestone's Frisco Building—Work is now under way on a
:w building for the Firestone Tire & Rubber Company in
ın Francisco, Cal. It will be at Van Ness avenue and Aus-
ı avenue, with a frontage of 70 feet on Van Ness and 319

Builds $15,000 Garage—The Jenkins Automobile Company, owned and managed by Judge F. M. Jenkins, Chippewa Falls, Wis., is having plans prepared for a large garage building, which will be the home of the Mitchell, Paige and Regal. The building will cost in the neighborhood of $15,000 and will contain a commodious and well-equipped repair department.

New Indiana Automobile Laws—Senator J. J. Netterville, of Anderson, Ind., has prepared a bill providing an annual license fee for automobiles, new speed regulations, and that the money collected from the licenses shall be distributed among the different counties for road building and repair purposes. It is estimated the licenses scheme would net from $250,000 to $300,000 a year.

Automobile Nuisances Past—The days of the loud horn or whistle, the open muffler, the smoking automobile are numbered as far as South Bend, Ind., is concerned. At a meeting of the Council committee an ordinance was approved to govern these matters, and as the committee is composed of the entire Council the ordinance will become a law at the next regular meeting of the Council.

Boat Company's Garage—The Portage Boat & Engine Company, Portage, Wis., manufacturing manual and power boats and motors, intends to build a large garage at Portage beginning this winter. The building will have ground dimensions of 40 feet by 132 feet, one story and basement of fireproof construction. At present the motor car selling, repair and storage business is conducted at the boat factory.

Fire Apparatus a Success—The automobile fire apparatus used in Baltimore, Md., has proved such a success that the Fire Board has decided to ask the Board of Estimates to allow an appropriation for converting at least four engines into automobile steamers. It is also planned to replace the horse-drawn vehicles used by the district chiefs with automobile wagons similar to those used by the chief and deputy chief.

Stoughton Garage Completed—Thomas Oscar and M. O. Flom, owners of the firm of Oscar & Flom, Stoughton, Wis., have completed their new garage building on North Water street, but it will not be completely ready until March 1. The garage will contain a large repair shop, offices and storage rooms, and a 3-ton elevator will be installed. The building is 46 feet by 90 feet, two stories and basement, with a one-story addition, 26 feet by 35 feet.

K-W Lighting Generator

Low-Tension, Three-Magnet Apparatus Produces Enough Current for Two 15-Watt, 16-Candlepower Lamps

New Device Has No Brushes and Wound Armature—Is Driven from Flywheel or Fanshaft

THE K-W Ignition Company, Cleveland, has brought out a low-tension, three-magnet machine, Model LS, Fig. 1, which has sufficient capacity to light two 6-volt, 2.5-ampere, 16-candlepower lamps when driven at speeds of from 900 to 3,000 revolutions per minute.

The constructional features of the latest instrument are identical with K-W practice. Like its K-W low-tension generator the new machine in standard form is intended to be driven by a friction wheel which bears on the flywheel face. However, if the latter is inclosed, the magneto may be driven from the fan shaft by a pulley. There are three optional sizes of friction wheels, with 3, 4 and 5-inch diameters, respectively. Any size of pulley from 1.5 to 6 inches is furnished to suit specific conditions.

The new magneto stands 9.5 inches high, has an overall length of 7.5 inches and a width of 4.5 inches. The weight is 18 pounds. When used for ignition purposes, this magneto must be operated in connection with a spark coil which is supplied at an additional cost. The instrument is not intended for use in connection with any type of battery whatever, and further, it cannot be used for battery charging, since the current which it furnishes is alternating. The latter current is not adapted for storage battery charging.

Fig. 1 shows the mounting of the magneto in a special bracket on its side. This bracket is fitted with springs on which the front end of the magneto rests. The function of these springs is to hold the friction wheel in contact with the flywheel face.

The peculiar internal construction of the K-W magneto or generator is shown in Fig. 2, which is a view with the lower part of the base removed. The rotor, seen more clearly in Fig. 3, is mounted in two ball bearings C, Fig. 2, one at either side of the side pieces.

In the K-W patented construction, there are no brushes, or other sliding contacts and no wire-wound armature. Instead of the latter there is a stationary, flat spiral winding, Fig. 4. which is fixed as at A, Fig. 2. On the rotor shaft, there are two inductors or segments B, the axes of which are at right angles. These revolve between the poles or ends of the magnets, and in the brass case, which is practically waterproof when the lower portion is in place.

In revolving, the ends of these inductors B cut the lines of force passing from one set of poles of the permanent magnets to the other set, thereby inducing a magnetic flux in the stationary winding, the direction of which is reversed four times per revolution of the rotor, that is, every time the lines are cut by an end of one of the segments B. The current is conveyed to the binding posts at the end of the magneto through the terminals of the winding which extend up through the top of the rotor case, connecting with these binding posts.

New Maxi Carbureter

Low-Speed and Intermediate-Speed Jets Are Aided, at High Speeds, by Nozzles Bored in Arc-Shaped Member

After the Carbureter Has Once Been Fitted, No Adjustments by the User Are Required

A MULTIPLE-JET carbureter which does not require to be adjusted after having once been installed on a car and suited to its specific requirements, is made by the Maxi Company, 37 Wall street, New York City. The construction of the device is clearly seen from Fig. 4. Gasoline is admitted at A2, passes through a screen S and the passage P controlled by the needle N into the float-chamber which contains the copper float F. The operating principle of the float is conventional and requires no explanation; the priming device which is shown at P1 is equipped with two springs, the only ones used in the apparatus. The gasoline leaves the float-chamber by way of the exit passage E, after passing through a second screen S1.

Fig. 4 shows the carbureter with the throttle in the closed position used when starting. In this case, the gasoline flows from the float-chamber through F1, G2 and G into the low-speed nozzle G1 which protrudes through the throttle T, being surrounded by an air hole H. The latter, in practice, is so proportioned that the throttle when turned in the direction of the arrow clears G1. At low speeds, air is supplied principally through A, although a little enters through the open mouth A1 of the throttle tube. When the throttle is opened slightly, gasoline flowing up through G3 is sprayed at the mouth of G4, and when the throttle is opened still further, fuel rises through the pipes R, fills the horizontal pipe H and is atomized at the ends of the bores formed in the arc-piece A3 which communicate with H. These bores or high-speed nozzles come into action, as the throttle uncovers them on its downward rotation. The capacity of G4 is determined by the passage formed in the plug G3; likewise, G2 and G determine the capacity of G1, thus permitting the adaptation of the carbureter to the requirements of the motor. The low-speed gasoline nozzle is bored with a No. 55 drill, air hole H with No. 60, the passage P and that above G3 with No. 55, in the case of a 1-5-inch carbureter. This carbureter is 5.5 inches wide, 6 inches high and weighs 5 pounds. The carbureter is made in four sizes, 1, 1.25, 1.5 and 1.75 inches.

Merralls Compressed-Air Starter A Rotary Engine

Device Is Shaped Similarly to Centrifugal Pump, But Contains Six Pistons Working in Individual Cylinders Secured to Casing—Ingenious Operating Mechanism Controls Valves and Connects Starter with Crankshaft

The Air Needed for Starting Is Stored in a Tank Which Is Supplied Either by An Air Compressor Driven by the Engine, or by an Explosion Air Valve Operated by the Impulses in the Engine Cylinders

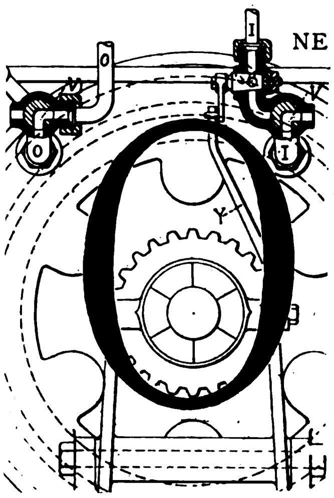

Fig. 1—Merralls starter

ONE more self-starter has been announced this week, which is of the rotary engine type and operated by compressed air, generated either by an air compressor or an explosive air valve, actuated in each case by the engine and storing the air in a tank. The Merralls starter consists of five small compressed-air motors of the reciprocating type which are inclosed in a circular casing and the connecting-rods of which actuate an eccentric mounted on the driving shaft of the starter.

The details of construction of the Merralls starter are shown in Figs. 1, 2 and 3. Fig. 2 is a view of the interior of the device, as seen after the front cover has been removed. Five small motor cylinders M are pivoted at Q to the casing, the pivots containing the ball bearings. The small working pistons P which are fitted into the cylinders M bear upon the eccentric E of the driving shaft D, which eccentric is formed integrally with piston P1 working at the bottom portion of the casing. As Fig. 3 shows, the inlet pipe I provides an admission passage for the air actuating the cylinders, which enters at the point where I connects with the casing C and passes through a bore in the same into spaces A1 opening into the interior of the six cylinders M. The bore being located at the outer ends of the cylinders, the compressed air forces the pistons in the cylinder toward the axis of shaft D around which the eccentric is revoluble. The pistons are so set upon the eccentric attached to E, Fig. 2, that each piston receives its impulse when positioned tangentially, relative to E. The impelling air exhausts through bores in the cylinders nearer to the center than the inlet bores, and thence it streams to the outlet pipe O, Fig. 1. Fig. 3 also illustrates the mechanism by means of which the admission of air to the starter is regulated and which incidentally throws the starter in and out of gear with the gear secured on the crankshaft for starting the motor. An arm A is connected to a handle or pedal in reach of the driver and is linked to a lever L fulcrumed at Q1 and pivoted at Q2 to levers L1 and L2. L1 is connected to a small lever which governs the inlet valve V, Fig. 1, which is operatively connected with the outlet valve V1, so that both are opened and closed simultaneously. Thus when A is pulled toward the left, referring to Fig. 3, air passes through the starter and the shaft D is rotated including the slidable dog F keyed to it. As the movement of A which admits air to the apparatus also moves the dog F away from the casing, F is brought into engagement with the dog F1 formed integrally with a driving gear G1 meshing with a driven gear G2 on the crankshaft; due to this engagement the gear is driven in counterclockwise, looking from C toward G1. As the engine is started and travels faster than the starter, F1 becomes the driving dog, and F, which carries no load, an idler which travels faster than F1 and is thereby thrown out of mesh. This moves Q2 toward the starter casing and shuts off the air valves. The starter may be made to suit various car designs, and fitted to the cars so as to drive a gear on the crankshaft or the flywheel. It is the invention of W. A. Merralls, New York City.

Cahill Special Shock Absorber Designed for Ford Cars; Diamond Tire Sleeve and Repair Patch; Ionides Automobile Information Calculator; Emil Grossman Gradient Meter; Allen Radiator Cover for Winter Traveling

Cahill Shock Absorber for Fords

A CONSIDERABLE number of accessories announced during the past few months have been constructed especially to increase the comfort of drivers and owners of Ford cars, and the latest addition to the list of these devices is the shock absorber, or rather compensating shackle, Fig. 1, which is made by the Cahill Auto Works, Incorporated, 1700 Broadway, New York City. This device is constructed to take the place of the rear-spring shackle on a Ford car, each set of Cahill shock absorbers comprising two shackles which are dimensioned to fit in place of the standard, ordinary shackles. The latter are, as is well known, of the common shackle design, shaped a good deal like the links of a driving chain, and have one cross pin secured to the spring support and another to the longest lead of the cross spring. The Cahill shackle, on the other hand, consists of two pins, a pair of stems, a spring coiled around each stem and a cross-head connecting the upper ends of both stems. The two pins are secured to the spring support and spring end in the same way as the pins of the ordinary shackle, and the connection between them consists of the stems. which are fastened to the spring-end pin, and the coiled springs surrounding the stems and pressing against the top cross-head, which are secured to the pin carried by the spring support

Allen Winter Radiator Cover

With the approaching of the cold season the Allen Auto Specialty Company, 1926 Broadway, New York City, known as makers of tire covers and tire gauges, has added another accessory to its line. This new product is the Allen radiator cover shown in Figs. 6 and 7. Its front side is made of imitation leather while the inside which bears against the radiator front. is of robe plush, distinguished as a poor conductor of heat. The leather is cut to a size fitting a certain class of cars, ranging from 25 to 60 horsepower. The central portion of the cover is attached to the main body by a seam along its lower edge, so that the lowest portion of the radiator surface is always protected when the cover is in place. The central portion may be bent down along this seam and secured in place by any one of the three pairs of snap fasteners which are provided on the main body of the cover. Thereby, only the top or a greater portion of the radiator may be exposed to the wind created by the moving car, or the whole front surface may be covered if the weather is very cold. The lowest portion of the radiator, however, is always protected when the cover is in place. A strip attached to the top portion covers the uppermost part of the central part when the latter is fully covering the surface, preventing snow or rain from getting on the radiator. A flap formed on both sides of the cover and one on top adhere to the longitudinal surfaces of the radiator, and the top flap is cut in the center so as to fit around the radiator filler cap, while the bottom section of the cover attaches to the car by straps which may be drawn through the two eyelets provided in that part of the accessory. The straps are, of course, fastened to the car in the most suitable way, depending upon the make and design of the car. The appearance of the product is distinguished, while the materials used inspire confidence in its efficacy.

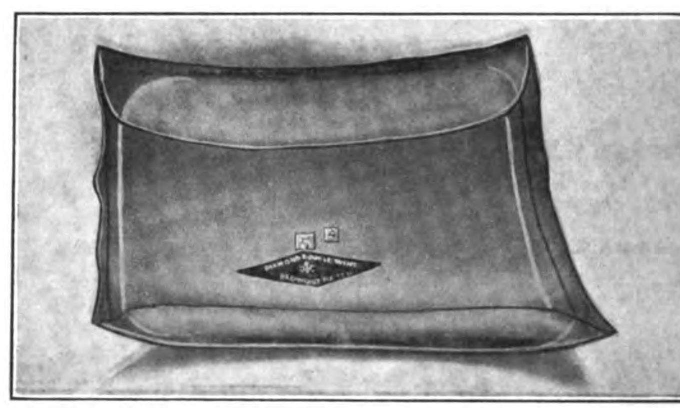

Fig. 2—Diamond tire inside blowout patch

Emil Grossman Gradient Meter

The Emil Grossman Company, 250 West Fifty-fourth street. New York City, has begun to manufacture a simple gradient indicator, the E. G., Fig. 5. This little device is made of nickel-plated steel and is of the shape shown in the illustration. To indicate the grade of the road over which the car travels, a curved glass tube is contained in the metal casing, and this tube is filled with alcohol and contains a metal ball which rolls on the glass track formed by inner surface of the tube. The ball naturally assumes at all times the lowest possible position, and by combining the glass tube with an indicator scale giving the gradient in per cent., the incline may be easily gauged by a simple look at the device. The latter is simply attached to a horizontal surface of the car, such as one of the side boards fitted to the driver's seat, being held in place by screws passing through two holes in the base plate of the casing.

Diamond Tire Patch and Sleeve

The Diamond Rubber Company, Akron, O., has increased its line of tire repair specialties by a blowout patch and a tire repair sleeve, Figs. 2 and 3. The blowout patch is made of several layers of Sea Island cotton frictioned together by Para rubber; the form of the patch is a rectangle differing slightly from a square. The inner portion of the patch is thicker than the peripheral one, which latter consists of only one layer of fabric and is formed with two flaps which are laid around the head of ıe casing, when the patch is put in commission between the ame and the inner tube.

Fig. 3 shows the repair sleeve which is furnished together with ıe inner patch shown with it. The latter goes between the ıbe and casing to tighten the latter at the place where it is reıforced externally by the sleeve. The patch is of a fine grade f cotton and made thickest in the oblog, central section, the xterior surface is made with a fine, rubber-like finish. The leeve itself is made of Sea Island duck and of high-grade ruber, in order to give excellent service. It is, of course, desired, o fit Diamond tires, and is thus made in a number of sizes /hich fit tightly around the relative sizes of tire casing, when he tubes inside the same are fully inflated. To put the sleeve ı place, the following process is carried out. The inner tube ; deflated and the patch placed between it and the casing at the lace where it is desired to strengthen the fabric of the latter. 'he rim portion of each side of the sleeve is fitted with four teel hooks designed to fit under the bead of the rim, between he same and the rim of the casing; it is an easy matter to put ıe sleeve in place by positioning the hooks,

Ionides Motor Calculating Device

A handy instrument by means of which automobilists may asily determine the speed of their engines or cars, as well as he ton mileage obtained per gallon of gasoline, is the Ionides ıotor calculator, Fig. 3. This device is the invention of A. G. onides, designer of the English Polyrhoe carbureter and works pon the principal of the circular slide rule; it has a thick cardoard base, 5 by 5 inches, to the center of which are secured six hin cardboard segments, marked with various values correponding to the dimensions or performances of the car which is ıe subject of the calculations. The following tabulation gives

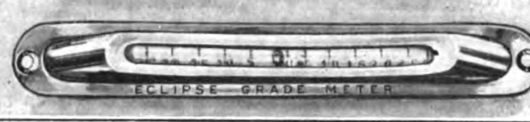

Fig. 4—Ionides motor calculator. Fig. 5—E-G gradometer

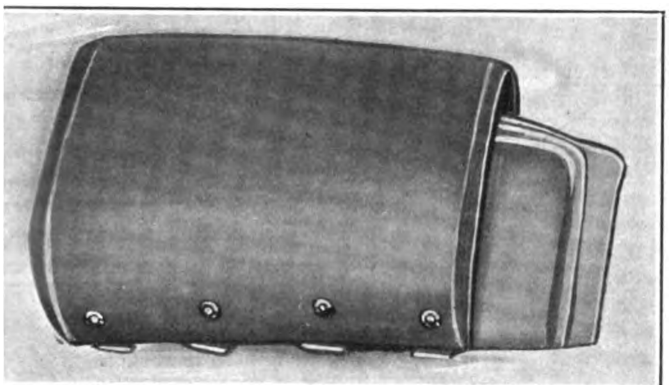

Fig. 3—Diamond clincher casing sleeve and patch

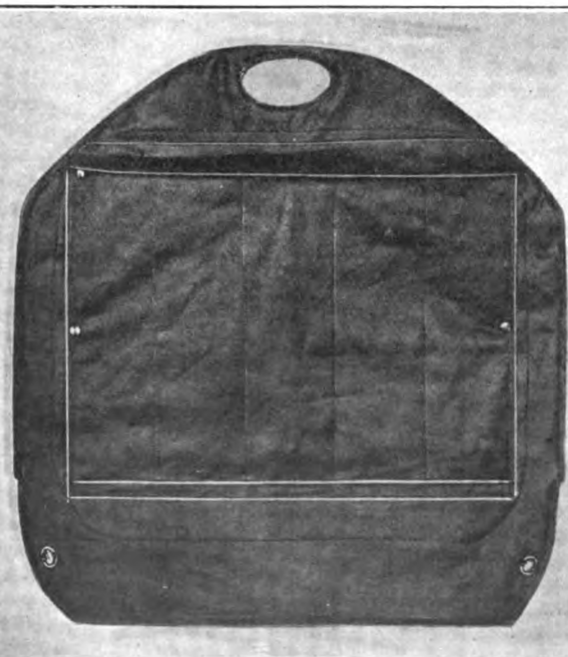
the number of bases provided on the board together with the subjects appearing on its face:

Base	Ton-miles per gallon and miles per hour.
1	Bore, weight, car-miles per gallon and R. A. C. horsepower.
2	Number of cylinders.
3	Stroke of cylinders.
4	Engine speed and number of driven teeth on axle.
5	Number of driving teeth, miles per hour and road wheel diameter.

The segments are independently turnable around the central fastener and by bringing certain points of information to register, others may be read on certain scales. For instance, if one desires to find the ton-miles per gallon the weight of the car is set against an arrow marked for this purpose on the first segment. If the ton-mileage per gallon is known, which may also be calculated by means of this device, the car-miles made per gallon of gasoline may be readily fixed, an arrow in the base cardboard pointing toward a scale marked on the first segment. The Ionides calculator is made by the Motor Calculator Syndicate, Bank Buildings, Kingsway, London, W.



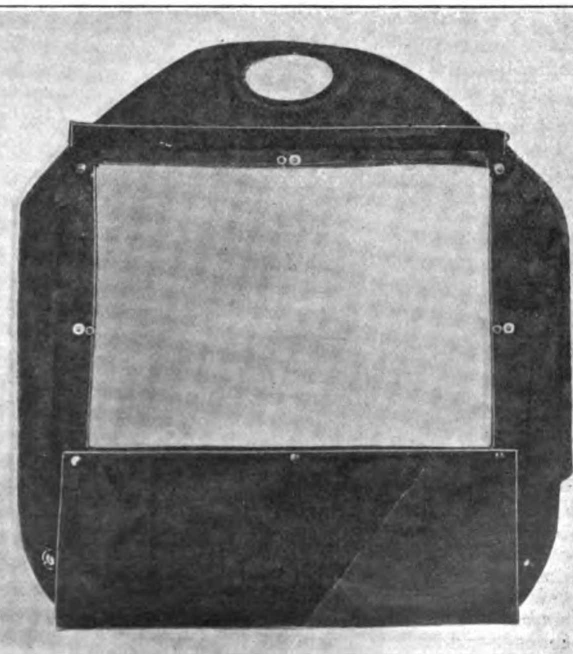


Fig. 6—Allen radiator cover fully closed to protect surface. Fig. 7 —Allen cover two-thirds opened

AUTOMOBILE **Carbureter**—In which a valve operated in conjunction with the throttle regulates the flow of the fuel.

This patent has reference to a carbureter, Fig. 1, in which a mixing chamber C is formed with an air inlet tube A and an outlet passage O; A is fitted to C as a downward, central extension and its communication with C may be interrupted by the valve V which is fitted over the top edge of the inlet tube and is shaped as an obtuse cone. A valve stem fitted centrally to the upper surface of V bears in a bored portion of the carbureter cover, and is surrounded by a spring S which ordinarily presses V against its seat. Fuel is supplied to the carbureter through a jet projecting upwards out of a vessel D fitted to lateral extension of C. Fuel enters at G, which is a short pipe ending immediately above the bottom of D, and fills this vessel to a certain height. A tube T is fitted into D and projects up into the lateral extension of C, the outlet of T being controlled by a valve V_1, adjustable on its seat through a knurled screw C_1. The valve stem of V_1 is connected to the throttle valve V by connecting means M fulcrumed at F, the fulcrum being adjustable from the outside of the casing and having a fork supporting the stem of V_1 resting on it.

No. 1,044,314—to Frank C. Watson, Des Moines, Ia. Granted November 12, 1912; filed February 5, 1912.

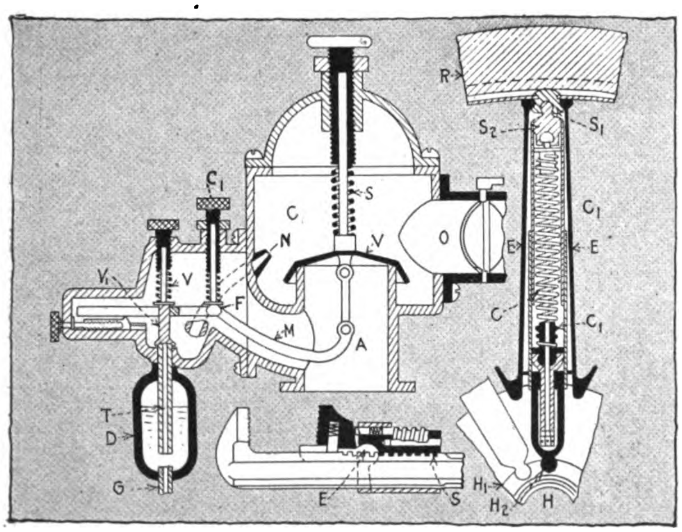

Fig. 1—Watson positive-working carbureter. Fig. 2—Mossberg pipe-wrench design. Fig. 3—Wilkes automobile spring wheel

Pipe-Wrench Construction—In which a frictional contact between the relatively movable parts is used to keep them in fixed relation.

A wrench, Fig. 2, is the subject matter of this patent. It consists of a long rod or shank on which a jaw D is fixed and on which operates a sliding member. The latter is provided with a jaw J pivotally mounted on it, and carrying a pin which is in contact with the rod.

No. 1,044,069—To Frank Mossberg, Attleboro, Mass. Granted November 12, 1912; filed November 2, 1911.

Automobile Spring Wheel—In which sockets fixed to rim and hub carry the spring ends.

The wheel, Fig. 3, has a rim R and a hub H, and telescoping spokes S. Socket pieces S_1 with sockets S_2 are fitted to the rim, while the hub is equipped with sockets H_1 in which heads H_2 are pivoted. Both sets of sockets are fixed to the spoke tubes S which are enclosed in elastic sheaths E and contain a coiled spring C each. Every spring is fixed to a detachable head fitted to each rim and hub socket.

No. 1,044,324—to Paul Wilkes, Cleveland, O. Granted November 12, 1912; filed May 20, 1909.

Adjustable Electric Headlight—In which the lamp socket is fixed to the casing and the reflector movable for focusing.

The lamp, Fig. 4, described in this patent comprises a casing C into which a post or socket P for a bulb is fitted. A sleeve movable on P is fitted into the apex of a parabolic reflector R which is in place inside the casing C. The rim of the reflector is formed with a cylindrical flange F which engages slidably a corresponding flange F_1 formed on the casing. A screw adjustment S piercing the casing C permits of moving the reflector sleeve on P, thereby altering the focus of the light.

No. 1,044,791—to William F. Anklam, Detroit, Mich. Granted November 12, 1912; filed May 16, 1912.

Rotary-Cylinder Valve—A cylinder slotted with passages registering with the ports in the engine-cylinder heads.

The subject matter of this patent is seen in Fig. 5. A valve, which serves for the inlet and exhaust of a multi-cylinder engine, is composed of split shells S fitted into a cylindrical casing C. The ends of the shells are beveled and engaged by terminally conical members formed so as to prevent axial displacement of the shells. The latter are formed with ports P registering with the cylinder ports. A spring S_1 presses the shells securely together.

No. 1,043,816—to Gilbert R. Elliott, Boston, Mass. Granted November 12, 1912; filed August 23, 1911.

Gas Engine Design—In which the fuel supply passage is periodically opened to the atmosphere.

This patent refers to an engine, Fig. 6, which has an inlet valve capable of being opened to the atmosphere and being properly actuated. An exhaust valve is operated by a cam on a shaft which carries another cam, and by means of moving the shaft alternately in a lengthwise direction, both exhaust cams are alternately brought into play.

No. 1,044,289—to John D. Taylor. Granted November 12, 1912; filed April 25, 1910.

Combination Automobile Signal—In which a bulb or an electric motor produces the sound

This patent refers to a signal comprising means for producing sound either by the action of an electric motor striking a diaphragm at intervals, or by a reed and trumpet which latter opens into a projector extending forwardly from the diaphragm mentioned above. The walls of the projector are diverging and open into a bell mouth, whereas the other end of the projector is attached to the diaphragm which affects the sound waves emerging from the open end of the projector.

No. 1,043,704—to Miller Reese Hutchison, New York, N. Y. Granted November 5, 1912; filed May 4, 1910.

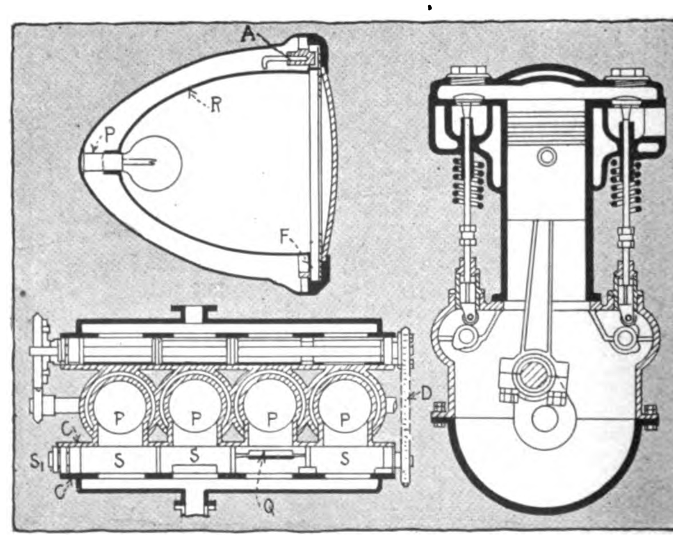

Fig. 4—Anklam adjustable headlight. Fig. 5—Elliott rotary cylinder valve. Fig. 6—Taylor internal-combustion motor

VOL. XXVII NEW YORK—DECEMBER 5, 1912—CHICAGO NO. 23

The AUTOMOBILE

Gotham Building 45 Fire Houses

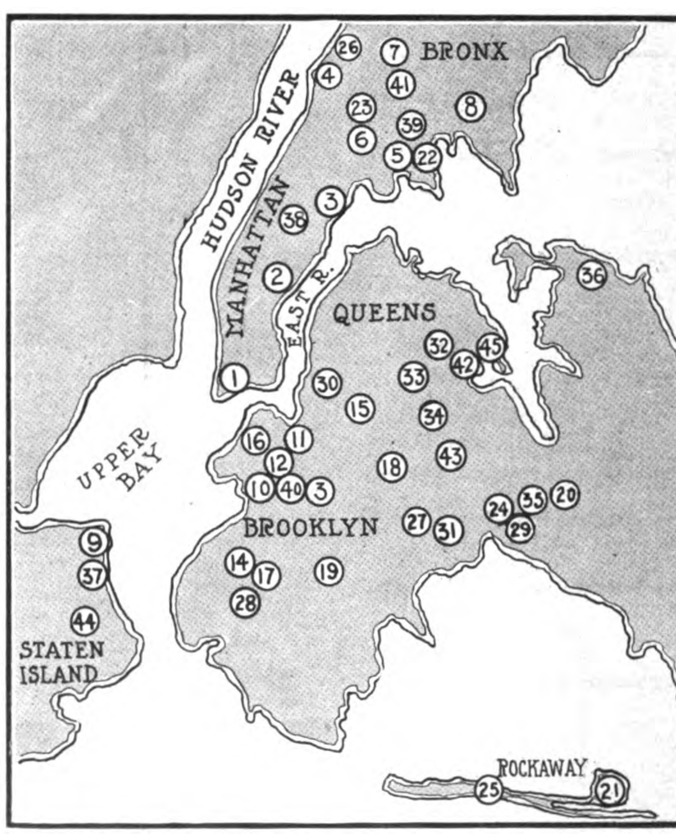
All of Them Will Be Equipped with Motor-Propelled Fire-Fighting Apparatus, Some of Which Is Now Delivered—No Horses Displaced by Present Order or in Near Future

Department Considers Project in Light of Giant Experiment Despite Investment of $700,000 in Equipment—Motorization Is to Come Later

WHEN bids were opened at Fire Headquarters November 26 it was learned that twenty-five out of the twenty-six new aerial trucks which will constitute a part of the fire aparatus to be installed in the forty-two new fire houses had fallen to the American-La France Fire Engine Company in two lots. The other truck went to the Seagrave company.

The trucks will be furnished as follows: Seventeen 65-foot trucks, American-La France Company, at $125,698; eight 75-foot trucks, American-La France Company, $63,152, and one 85-foot truck, Seagrave Company, $8,210.

The other motor-driven fire equipment now contracted for consists of thirty-one combination chemical and hose wagons and high pressure hose wagons, which contract was let July 16 to the International Motor Company, manufacturers of the Saurer, Hewitt and Mack trucks.



How the new fire houses are distributed in five boroughs of Greater New York, showing twenty-eight on Long Island, three on Staten Island and the rest in Manhattan and the Bronx

The tractor-drawn steam pumping engines will be furnished by the American-La France Company to the number of twenty-eight. This contract was let August 15 and with the above item was chronicled at the time in THE AUTOMOBILE.

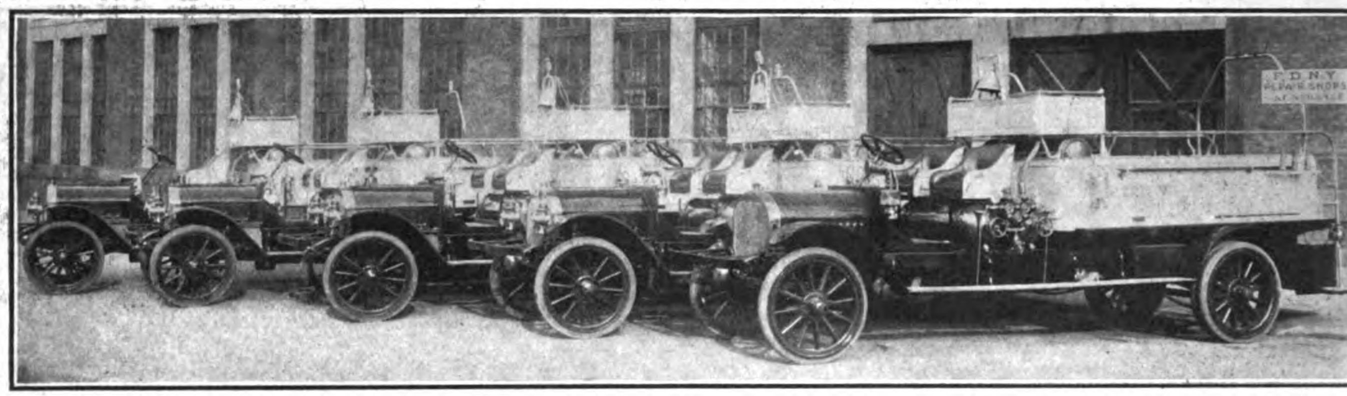
All told the expenditure represented by the eighty-five pieces of new apparatus amounts to about $700,000 and the appropriation is just about exhausted. What the future holds in the way of additional thews and sinews, in other words funds with which to buy more apparatus, is in the lap of fate—nobody knows. In a large measure it depends upon the character of the showing made by the new apparatus.

New York to date has in service four trucks, two water towers, one gasoline pump, two tractor-drawn steam pumps and eleven hose wagons, all motor propelled. The hose wagons and some of the trucks have been thoroughly tested and have proved satisfactory. They are all installed in houses that used to be occupied by horse-drawn equipment and consequently have been subjected to some disadvantages that will not be laid against the new pieces.

By the first of the year or shortly thereafter, twenty of the forty-five new fire buildings will be turned over to the department for occupancy and the completion of the rest is scheduled for various times during 1913.

Taking up the subject of the houses first and the apparatus afterward, the following description of the New York Fire Department outlines the situation as it is at present.

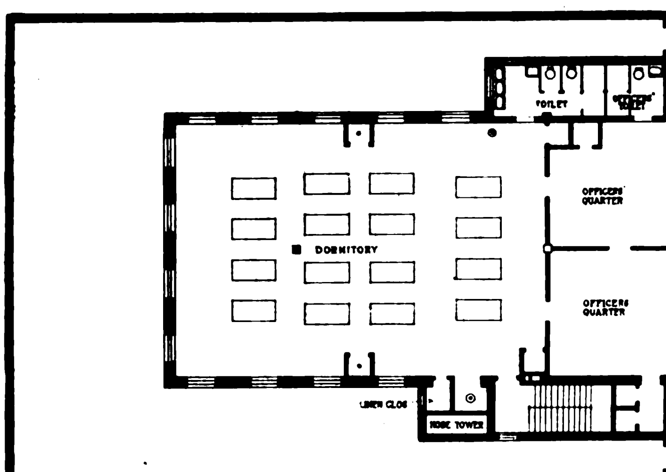
The budget for 1913 calls for $8,945,945, of which about $8,000,000 is for salaries and wages. No permanent additions and im-



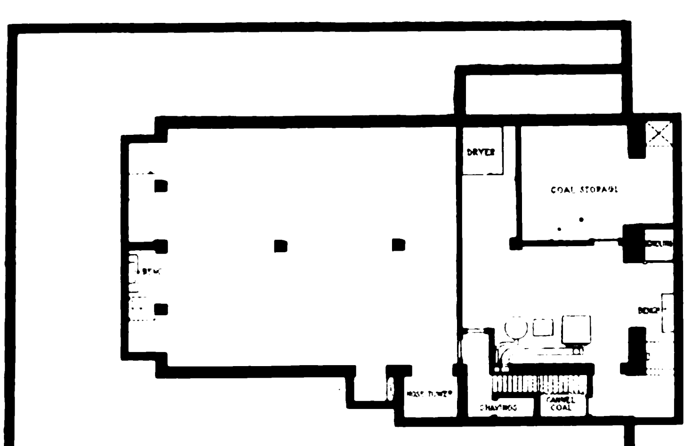
First delivery of combination chemical and hose wagons by the International Motor Company on the present order for apparatus

provements, including apparatus, is considered in the budget and the only item of much importance to the automobile equipment of the department is an item of about $26,000 for maintenance and repairs and another of $12,000 for gasoline. Of course the manufacturers' guarantees provide for certain kinds of replacements, but the item for maintenance and repairs seems inadequate, especially when such a large number of new pieces will be placed in commission during the period covered by the appropriation.

The purchase of fire house sites, building of the houses and their equipment is provided for by the sale of municipal stock and has all been settled. The houses provided under the last sale of stock number forty-five and are located as shown in the accompanying map of New York. Manhattan Island is to have six; Bronx, eight; Brooklyn, fifteen; Queens, thirteen, including two at Rockaway, and Richmond, three.



Dormitory floor, showing sleeping quarters of company



Basement plan of same house, showing storage space

Of these houses forty-two are to be fully equipped with fire apparatus. The other three are to be telegraph and signal stations.

There will be sixty-one full companies stationed in the various houses and some of the houses will have as many as three companies assigned to them.

One fact should be constantly borne in mind in considering the fire department situation in New York. The horse has been displaced in only a very limited degree. The twenty pieces of apparatus now in service displaced horses and the departmental officers who use passenger automobiles in place of the time-honored buggies have displaced horses, but the new apparatus will not take a single job from a single horse.

That is to say, the new houses equipped with motor apparatus will be extensions of the department and not in any sense substitutes of motor equipment for horse-drawn equipment.

If the giant experiment proves to be successful, then the horse will be gradually rooted out until the department is completely motorized.

Of the forty-two fire houses, thirty will be for the accomodation of one or more pumping engines and a truck; four will be occupied by hook and ladder trucks alone and the other eight will house single engine companies.

The total cost to the city will be $2,153,800 and the motor equipment will cost an aggregate of $1,259,000. Of this sum about $700,000 has been covered by the present contracts.

New Houses Last Word in Construction

The new houses have been designed by three firms of architects, Frank J. Helmle, Hoppin, Koen & Huntington and Morgan & Trainer. They represent the last word in fire-house construction and constitute the first attempt of the New York Fire Department to comply with the law covering the storage of combustibles. To the outsider it seems rather strange that the fire department itself, operating a number of establishments that are in legal effect garages pure and simple, should violate the law covering garage construction. This, however, has been the case since the enactment of the combustibles law as applied to New York structures.

In the new houses the law is strictly observed. This point alone caused the department much anxiety, but the plans submitted cover the situation rather ingeniously. The law provides that gasoline shall not be stored within any building where the fumes may come into contact with live fire such as is required to keep up steam in the boiler located below the station of the fire engine. The way the department gets around the difficulty in building the new houses is to provide no direct communication between the basement in which the boiler is located and the apparatus floor upon which the automobile fire engine stands with its tanks full of gasoline.

Thus the openings from the basement are not by stairways to the apparatus floor, but by stairs that open on the street. The arrangement of these stairs cuts pretty close to the letter of the law, because when an alarm of fire is sounded it is the duty of every man connected with the company to accompany the apparatus to the blaze. Of course, when men are off duty the rule is modified. Suppose that at the moment an alarm strikes in, one or more of the members of the company are in the basement attending the fire under the boiler or engaged in some other duty. To report to their officers is their first duty and unless they have a handy means of egress from the basement they may be unable to take their places on the apparatus. Excuses and explanations are at a very material discount in the fire department and consequently the architects in framing the plans for the new buildings have provided easy stairways opening toward the front of the house upon the street, so that men caught in the basement at the moment of an alarm can catch the engine, truck or hose wagon as they dart out of the house. At the same time the majesty of the law is not assailed.

As a general thing, the new houses are narrower than houses designed for a similar amount of horse-drawn equipment. The reason for this fact is that the motor-propelled apparatus does not require as much room as is needed for stalls in addition to a similar amount of space for the horse-drawn apparatus. Thus where the department has purchased a number of 50-foot lots the general width of the new double-houses is 42 feet. This means a saving in structural expenses and gives opportunity for better sanitation, more air and added economy in maintenance.

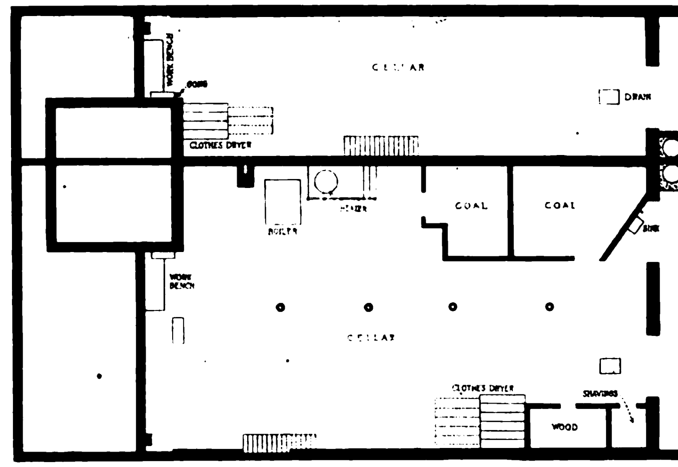
Brick, stone and concrete are used and the various types of buildings now under construction are far more sightly than those in service.

Improvements Embodied in New Buildings

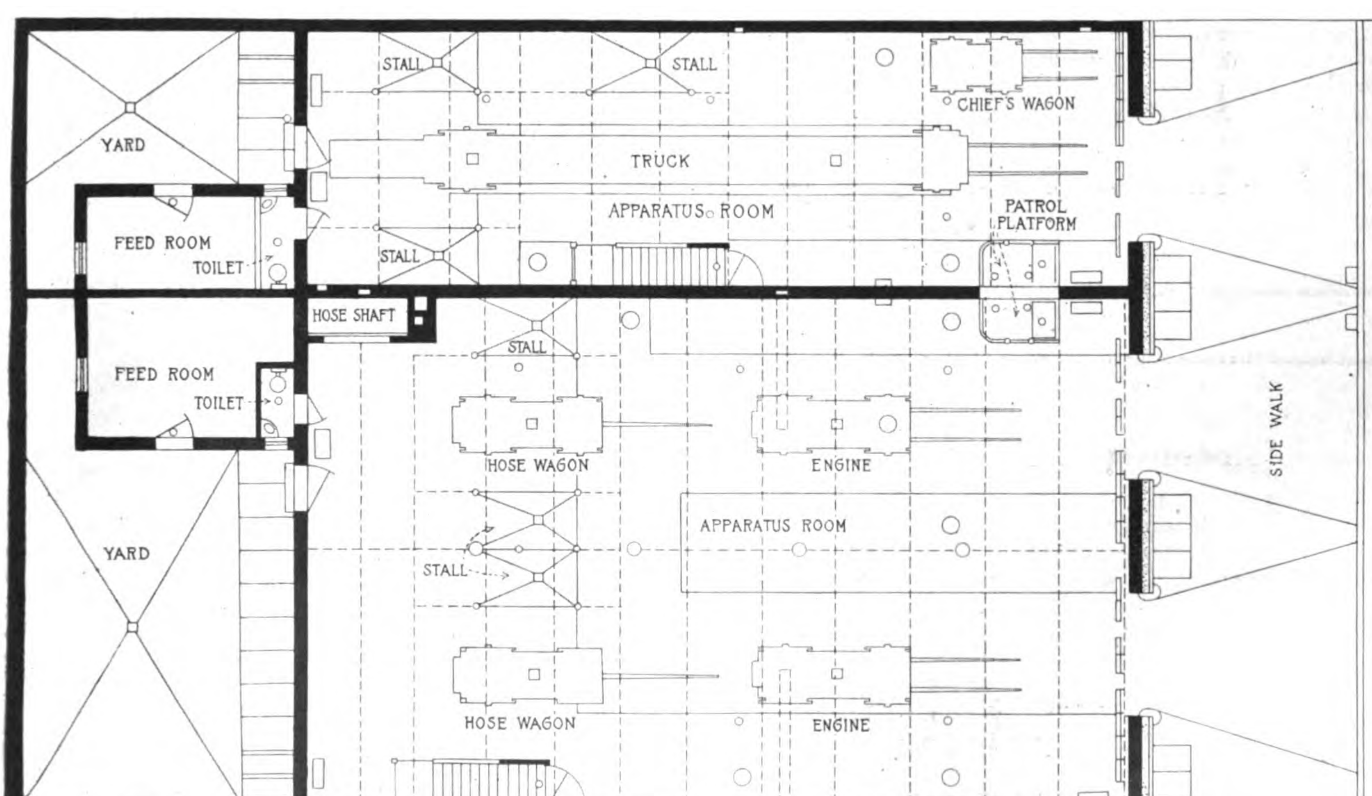
The houses are more compact than those of older styles. The basement and apparatus floors are of cement, the latter being tilted slightly for the purpose of facilitating drainage. The apparatus will be stationed in files. Take the new house on West One Hundred and Eighty-first street as an example. This house is one of the largest under construction and will have five pieces of motor apparatus, not counting the powerful runabout that will be used by the staff officers stationed there. The apparatus will include one of the new aerial trucks, which will be located on the right side of the house, well back from the entrance. In front of the truck will be the staff officer's runabout. Poles connecting the dormitories and officers' quarters are to be located in appropriate places near the truck and the runabout. There is no boiler in the basement on the right side of the house, as neither the runabout nor the truck require steam pressure. There are water connections for use in washing down the apparatus and flushing the floors. The middle section of the house will have one of the new American-La France tractor-drawn steam pumps, with poles, water connections and the other paraphernalia. This will be well toward the front, while at the rear will be one of the International Motor hose wagons with its pole and house equipment. Boilers will be placed below the steamers in the basement to maintain pressure when not in use.

The left side of the house will duplicate the middle section. There are to be three doors opening upon the thoroughfare and it has been estimated that the apparatus can be started away within 30 seconds of the time required to determine the location of the alarm box.

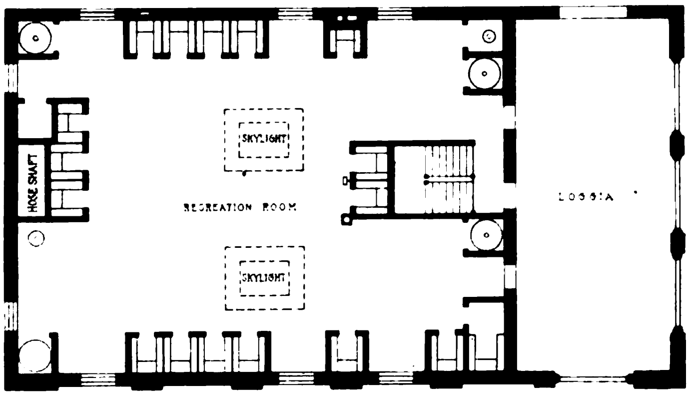
The second floor is devoted to sleeping quarters for the men and for offices and quarters for the officers. The officers are



Cellar plan of triple house, near Washington Bridge



Apparatus floor of Manhattan house, showing stations of six automobiles, five of which will be used for fire-fighting



Recreation floor of a Bronx house, comfortable and open

housed in front and the men in the middle and rear. The poles connecting the dormitory with the apparatus floor are located in such a way that sleeping men can be awakened, slip into their emergency clothing and shoot to their stations in an astonishingly short time. In some of the old houses specially trained companies have been able to start to a fire from deep sleep in a trifle over a minute after the first stroke of the alarm bell, but the average is not nearly so rapid. By the new arrangement it is predicted that this record will be reduced by at least 15 seconds.

The sleeping quarters differ in only small details from the generally accepted practice. The requirement of the law so far as it applies to the number of cubic feet of air space allotted to each occupant of the dormitories has been complied with, leaving a big margin on the side of safety and comfort, despite the fact that the narrowing of the houses has limited the size of the sleeping rooms.

On the other hand, the numerical strength of a company assigned to operate a piece of motor-propelled fire apparatus is less than is required to use a corresponding piece of horse-drawn equipment and therefore the accommodations need not be framed on such broad lines as have been usual in the past.

The upper floor is given over to the recreation quarters. As a general thing the front portion of the floor is finished off as reading and lounging rooms. In some of the houses, particularly those of the very latest pattern, the rear half of the third floor is used as a kind of roof garden. The side and rear walls are not continued to their full height and the space is arranged for rest and recreation of the men.

The third floor is connected with the second and apparatus floors by various means of quick transit from one to the other. There are no poles from the roof garden to the lower floors, but the finished portion of the floor opens with swinging doors to the outside section and men who are enjoying the open air can reach the dormitory floor in case of alarm in 20 seconds or less and be at their stations on the apparatus in 30 seconds. As it requires an average of 40 seconds to receive and identify the alarm numbers, it will be seen that the new houses lend themselves to a high degree of speed in making response.

Manhattan Additions Supplementary

As to the location of the houses it may be said that the new stations on Manhattan Island are either supplementary to the existing horse and motor companies in the older sections or are intended to cover the newer northern sections of the island. The immense house on West One Hundred and Eighty-first street is an example of the second class.

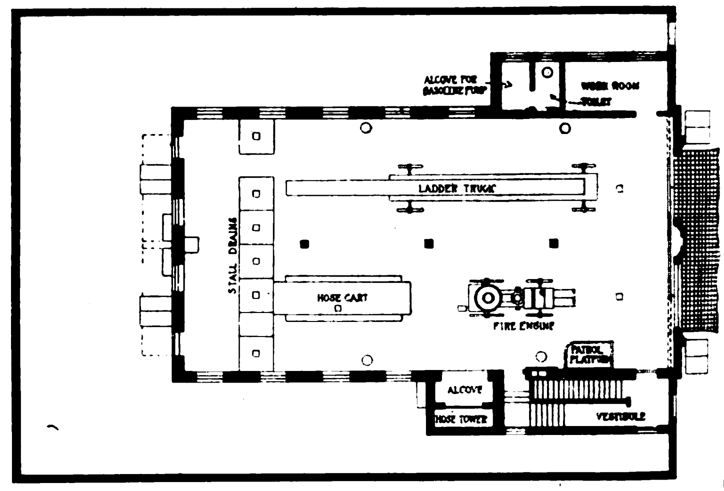
That house is located in the center of a densely populated district heretofore covered by horse equipment in large part. It is directly in touch with the wealthy West Bronx district, using Washington Bridge across the Harlem, and will be available on second call or subsequent alarms from Kingsbridge to Fort Washington and south for 2 miles.

The big hill at One Hundred and Fortieth street is usually considered as marking the division line for fire companies, but under the specifications for the new equipment it will be possible to take the hill and work still further south.

In the Bronx eight new houses are being built. They are purely supplementary to the existing horse equipped stations.

Brooklyn has the largest number of new houses under the present contracts and fifteen stations are under construction in that borough. They will serve the fast growing districts of the borough and supplement the present equipment.

The new houses in the Borough of Queens are somewhat different. Queensboro has an immense territorial area and is poorly covered by the fire department at present. The distances are excessive, particularly with horse-drawn apparatus.



Apparatus floor of typical double house in Queens

A winter fire in Queens, where the property involved or threatened is of considerable amount, is a terror to the department. It has been quite common in the past to answer alarms at a distance of as much as 4 miles. At the very best possible speed horses can cover such a distance, drawing a big steamer, in from 16 to 20 minutes. The average would be considerably higher, probably approximating 30 minutes. The physical exertion of the horses is such that no matter what the weather conditions they are covered with sweat and in a state of exhaustion near collapse upon arrival.

In big Queens fires of the past the loss of horses has been appalling. Also the fire losses have been heavy. Experts in the department say that one 4-mile run to a fire in cold weather is often enough to ruin the usefulness of a good horse, even if it does not serve to end his life. The whole modern theory of fire-fighting is based upon the utmost speed in reaching the seat of action and in Queensboro the territory expanse makes the horse prohibitively expensive and inefficient.

Queens Houses Serve Wide Territory

The new houses are located at various strategic positions where dangerous localities can be reached with concentrated effort in the shortest possible space of time. The companies will occupy single houses as a general rule; that is, the companies will have in charge a single piece of motor apparatus. Like the new houses in the Bronx, the combination chemical and hose wagon will be commonly used in Queens. Of course there will be steamers and a few trucks, but the real effective mechanism that will be installed in Queens is the combination chemical wagon.

The Richmond equipment will be contained in three new houses on the east side of Staten Island. These will be similar in general character to those in Queens.

Aside from the motor equipment now in service and that which has been ordered, the fire department has 182 steamers, 183 hose wagons, 99 hook and ladder trucks and 3 water towers, all horse-drawn. Some of it was manufactured over 30 years ago, but a large percentage of the apparatus is of the latest and most efficient types.

A tremendous amount of effort is spent to maintain the horse-drawn apparatus at top notch service efficiency, and even the older steamers show by their spick and span appearance and the avidity with which they attack their duties that they have been well kept. But still further, the care that has been expended upon the horse apparatus is an earnest of what will happen when the new motor equipment is installed.

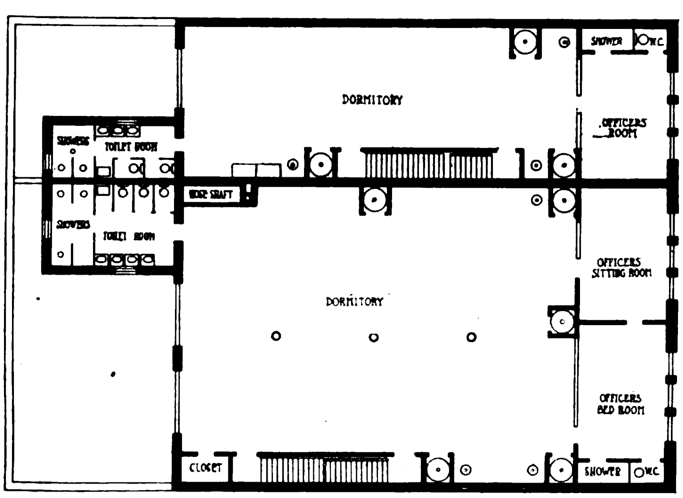
Fire departments have ample labor, money and time to maintain apparatus. On the other hand, the service is exceedingly severe when the call sounds and the factor of safety in the construction of fire engines must be liberal or the life of the piece will be short despite the care and attention that is given to all fire apparatus.

The subject of present and future motor apparatus for the New York department is of the widest importance. The present equipment is actually small compared with the size and importance of New York. Save in a very few instances the apparatus now in service was produced at factories that specialize in fire apparatus and not automobiles. Whether it be a consequence or no of that condition, it is nevertheless a fact that the New York fire department has had an enormous amount of trouble with its motor apparatus so far.

Of course it would be inconceivable to suppose a case where a great municipal department could change from horse-drawn equipment to automobiles without experiencing some sort of trouble and the New York department has had plenty of it.

Department Faced Many Difficulties

The legal regulations that surround the acceptance of any material thing have served to protect the department from money loss on account of the failure of some of the apparatus tendered for test, but those regulations have not prevented a series of blood-letting delays that followed the rejection of certain offered apparatus upon which high hopes had been built. For instance,



Triple company house, showing arrangements for sleeping

a gasoline pumping engine, motor-propelled, was submitted not long ago and according to predictions before the test it promised to revolutionize the whole system of fire-fighting. But the engine failed. It was an excellent automobile but a bad pump, under the rules of the fire department.

Complaint has been made that under the specification framed by the engineering board of the department automobile makers could not participate in the business because the specifications provided for apparatus that was essentially different from the stock product of the companies. Thus, big automobile makers did not bid for the jobs because the specifications provided for a different type of frame, axle, motor, steering gear or other essential or non-essential element not included in their stock product.

This objection might have been just under the old system, but the new apparatus was certainly ordered under about the most wide open set of specifications ever devised for such a big job. That automobile companies did not succeed in getting the whole order must be due to some other reason than that of tightness in the specifications.

An example of this breadth can be seen in the specifications submitted for bids on the thirty-one hose wagons. In the introductory paragraph the following note is published.

"For the sake of clearness it shall be understood that throughout these specifications wherever reference is made to the chassis it is intended to include the assembled automobile in each case without the body of whatever kind and before the finish is applied. It will be likewise understood that the chassis when referred to as such shall not include the mud-guards or the equipment, the latter being enumerated according to custom including lamps, tires, irons, generator, tool kit, registration and rubber tire kit.

"Whenever the body shall be referred to it shall be understood here and after that the mud guards shall be a part thereof and the running boards or steps, of whatsoever kind, shall also be classed with the body, but the mud apron or other protective devices placed to save the machinery equipment and the chassis from harm shall be considered as a part of the chassis.

Specifications of the Wide-Open Kind

"The fire-fighting equipment, as referred to hereinafter, shall include all the fire-fighting apparatus equipment, units or parts related thereto of whatever kind, all of which shall be hereinafter more particularly mentioned and described."

The specifications then go on to enumerate the size, quality and style of the various elements that go to make up the type of hose wagon approved by the department, particularly emphasizing the necessity of following the standards recommended by the Society of Automobile Engineers. In fact the specifications are so worded that the contractor must use the S. A. E. standards under a strict construction.

They are made to apply to the kinds of steel to be used in the various parts to the power plant, specifically providing for a motor with enough power to deliver a maximum of 30 miles an hour with full load and a maintained speed of 20 miles an hour for at least that period; to the frame, engine parts, valves, wheel dimensions and fastenings, tires and all the functional elements of the automobile where covered by the standards.

Throughout the specifications the same spirit prevails and the new hose wagon appeared to be such a thorough automobile under the regulations that the International Motor Company went into the matter with care and landed the whole job.

The first of the hose wagons is due 120 days after the signing

Flanders Creditors Meet

Merchandise Men Who Supplied Manufacturing Company with Material Confer About Prospects

Extension of 90 Days Asked—Majority Sign Agreement Giving Committee Power to Represent Them

DETROIT, MICH., Dec. 3—(*Special Telegram*)—Statement of the affairs of the Flanders Manufacturing Company, of Pontiac, Mich., was heard by the merchandise creditors representing 70 per cent. of the total indebtedness of the concern at a meeting held at the Pontchartrain last week. A committee of three was appointed to devise ways and means of continuing the business.

This committee, which was composed of G. W. Rogers, Goodyear Tire & Rubber Company, Akron, O.; S. T. Douglas, attorney for several of the largest stockholders, and W. S. Thomas, Wagnor Electric Manufacturing Company, St. Louis, represented the largest creditors and was instructed to report to a committee of seven composed of creditors next in order of magnitude. The latter was to act as an advisory committee to confer with the directors of the Flanders company.

The Flanders Manufacturing Company has a merchandise indebtedness of $500,000 and outstanding notes to the amount of $350,000, totaling $850,000. Assets including the electric vehicle plant, the motorcycle factory and other holdings of the company amount to $2,135,000. The company's financial difficulties are all through lack of working capital and the indebtedness, only $40,000 of which is held by concerns having credits under $2,000, can evidently be squared away in the event of the closing out of the business. Many of the creditors, however, are of the opinion that by raising about $200,000 it will be able to profitably escape from its difficulties.

The electric car plant has always been a money maker and the other holdings have been responsible for the present lack of working capital.

A meeting of the directors of the company will be held December 3.

A notice of the creditors' committee proceeding was sent to every creditor together with a forbearance agreement which he was requested to sign, thereby agreeing to waive the enforcement of his claim for a period of 90 days unless in the opinion of the committee earlier action was deemed advisable.

To date about 150 creditors out of the 500, besides the principal ten, have signed this agreement which extends to the committee an exclusive authority to act for the signers.

The committee now has control of the majority of the credits and can act with authority when conferring with the directors.

Crude Rubber Advances Slightly

The fortnightly auction in London which began Tuesday saw slightly better prices for the plantation grades, and while the Para grades did not respond, the tone was stiffer all around. The amount of rubber offered consisted of about 750 tons, 25 per cent. of which was from Ceylon. Smoked sheets rose to $1.08 1-2 and pale crêpe to $1.05 1-2. Up-river held its advance of last week after the first auction day, standing at $1.07 1-2.

General Vehicle Expands Capital

Changing the form of its business organization and enlarging its capitalization the General Vehicle Company has been reincorporated under New York laws for $10,000,000, divided evenly between preferred and common stock. The company has always been more or less of a close corporation and its character will not be changed by the new move. The present stockholders will be offered the option of taking the new issue, or as much of it as shall be issued at par. The present capitalization is $1,000,000.

The reasons for the increase are that the company requires more liquid capital to finance its plans for the immediate future. These plans include the installation of a huge factory for the manufacture of Mercedes trucks and also another large factory for the making of electric vehicles. The foundation of the new six-story building at Long Island City is completed.

The General Vehicle Company has been ultra-conservative until recently when it branched out into the gasoline field. It has been tentatively announced that there will be some additions to the present line of electrics and possibly some changes in the roster of officers.

W. C. & P. Leaseholds Sold

Leaseholds on the property occupied by Wyckoff, Church & Partridge, Inc., at Fifty-sixth street and Broadway, including the garage and supply store, have been sold by order of the United States District Court to H. M. Swetland, for the Swetland Operating Company. It is understood that negotiations are under way to transfer the property to a garage and selling concern, or to an operating company.

On Saturday the transfer of the property to the purchasing syndicate consisting of Messrs. Ellis, Griswold and Dickinson

Automobile Securities Quotations

Movements in the list of automobile securities during the past week were irregular. Some advanced; some stood still and some declined. Trade was not impressive in volume and the fluctuations resulted from the preponderance of buying or selling orders in a small market. Firestone was the strongest element in the list, scoring a rise of 13 points. Goodyear failed to hold its extreme advance to 450 and fell back 10 points on some small sales for profit taking. There was ample margin for such operations, as the stock has advanced $200 a share, practically without a setback. American Locomotive preferred rose sharply $4 a share, while General Motors, Goodrich, International and Studebaker sagged. The preferred issue of International broke rather sharply and on Tuesday showed a loss of $7 a share.

N. A. A. M. Car Bureau

Detroit Branch Will Strive To Keep in Touch with Automobile Freight Cars When Away from Home Lines

Peak of the Load Apparently Was Passed Earlier Than Usual and Shortage Is Slightly Less

THE National Association of Automobile Manufacturers has installed its service bureau at Detroit, according to announcement made by James S. Marvin, traffic manager of the association. The purpose of the new bureau is to facilitate the efforts of automobile makers to secure a supply of freight cars during the shipping season. The methods to be used will be largely precautionary. For instance, when a shipment of automobiles leaves the manufacturing center, the numbers of the cars are listed, together with their ownership and official designations. This list is forwarded to the railroad which will make delivery of the freight, with a letter requesting the terminal road to protect the cars and to see that they are promptly returned to the railroad from which the shipment originated.

A system of daily car reports has been instituted which will show the location of automobile freight cars, and thus tend to decrease demurrage and delay.

It has been found that fully 30 per cent. of the inefficiency of automobile freight cars arises from the withholding of foreign cars by terminal railroads under the present unsatisfactory system of demurrage. The association hopes to decrease this percentage to a material extent by the operation of the car service bureau.

The freight car shortage has turned the corner and a quick recovery to normal conditions is looked for in the traffic world. The peak of the load was passed about November 18 and the fortnightly tabulation issued by the American Railway Association covering conditions up to November 21 shows that the net shortage for that period was 51,112. As compared with the preceding report, this shows a lessening of the shortage by fifty-seven cars.

As an evidence of the strenuousness of the situation it may be said that at the corresponding period of 1911 there was a net surplus of freight cars amounting to 23,110. The peak of the load, however, was not passed in 1911 until a considerably later date.

The box car situation improved to a marked extent, the shortage decreasing from 44,000 to 38,465, and as the automobile industry is interested in the supply of a certain type of box cars the announcement has been well received. The greatest increase in the shortage was noted in the supply of coal cars.

The recent storms have not served to check the movement of grain and other agricultural freight which still continues in unprecedented volume. During the past 10 days, however, signs have developed indicating that the movement is due for a check in the near future.

Grain Moving Is 1912 Crop

Reports have been circulated that the grain that has formed the bulk of the movement so far is largely from the 1911 crops. This, however, is not borne out by investigation, as it is well known that the high prices of last spring caused the farmers to ship their grain and left the barns practically bare before the bumper crop of 1912 was harvested.

Orders for 13,500 cars were placed during the past week by the granger railroads serving the Middle West. Inquiries for 30,000 cars were made by other roads during the week. The Santa Fé and St. Paul roads contemplate spending $20,000,000 for cars and equipment in the immediate future.

Accidents of the Year On New York Streets

Vehicular Traffic Cost Lives of 486 Persons on Highways and Byways of Metropolis

Report Covering First 11 Months of 1912 Shows Total of 2710 Persons Killed or Hurt, Half By Automobiles

According to the report covering the first 11 months of 1912, issued this week by the National Highways Protective Society, of which Colonel Edward S. Cornell is active head as secretary, vehicular traffic accidents in New York City since the first of the year have been reported as follows:

Kind of casualty	Killed	Injured	Total
Automobile	201	1260	1461
Trolleys	121	667	788
Wagons	164	297	461
Total	486	2224	2710

Of the automobile fatalities ninety-three were children under the age of 16. Many of the cases reported were those of children skating or playing in the streets. The operation of toy wagons and pushmobiles was another source of accident. These two factors in the situation indicate that lack of adequate playgrounds for the children is accountable for at least fifty of the fatal accidents. It may be noted that one of the objects of the National Highways Protective Society is to secure adequate playgrounds.

But the fundamental protest raised by the society is against the reckless and illegal driving of a certain class of automobile owners and a certain class of chauffeurs.

Col. Cornell holds that when a fatality occurs, the license of the driver should be suspended automatically and that it should be reissued only upon due cause being shown for such action.

"The difficulty," said Col. Cornell, "lies in the single fact that certain owners and certain chauffeurs feel that they must exceed the limits of the law, good taste and good sense in order to attract attention to themselves and their cars. It is perfectly sure that the man who has owned high-grade automobiles since the beginning of the industry will not take undue chances and it is equally sure that the man who saves $1,000 and buys a car for the use of himself and family will be cautious and law-abiding in its operation. But the man who suddenly achieves wealth and who loses his perspective of life and the rights of others is the fellow who is a menace to the automobile as well as to the general run of citizens."

In referring to the chauffeur, Col. Cornell said that greater care should be used in granting licenses, but that such care would be useless unless some more stringent measures were used in preventing second offenses. He cited the situation in Connecticut to illustrate his point.

"During the past year," he said, "there have been eighty-six licenses revoked in Connecticut, thirty-four of which were held by owners of cars. Needless to say that casualties in Connecticut are not so numerous as they are in New York, despite the fact that the automobile law is more liberal in many respects than it is here.

"There is one thing upon which we can congratulate ourselves, however. Not a single non-resident of New York has been killed on the streets this year. The reason for this state of affairs is simple enough when one comes to look a trifle under the surface. For instance, when a resident of Prunty Corners starts for a trip to New York, his wife will caution him at the front gate, saying: 'Now, John, you know how fast the taxicabs run in New York and how crowded the streets are, so do be careful John.'

"And of course, John is careful. That helps some, but the curbing of reckless driving and the provision of playgrounds for the children will do more. Accidents will always happen so long as man is a finite creature but their number can be reduced by a general, decent regard for the other fellow's rights."

Among the fatalities tabulated above there was one in November where a horse car ran over and killed a child. This will probably prove to be the last accident of that kind in the city as the last of the horse cars will be seen soon.

In New York state eighty-nine persons were killed and 123 injured in grade crossing accidents. A large part of this appalling list resulted from the running down of automobiles on crossings. During the period of 11 months, forty-seven cars were struck and fifteen persons were killed. The society is opposed to grade crossings and is constantly doing a lot of active work to eliminate them by law. Of all the accidents on the list those at grade crossings appear to have the least basis of excuse or explanation.

According to the report the vehicular accidents in Vienna during 1911 resulted in sixty-four deaths and the injury of 2,169. Of these, the automobile fatalities numbered twenty-four.

In Berlin the vehicular fatalities were 129, of which those charged to automobiles numbered twenty-eight.

In Paris 236 were slain in 1911, of which 103 were charged to automobiles.

In London 410 met death in vehicle accidents and 262 were charged to automobiles and motor busses.

In 1911 the report shows that 417 persons were killed by automobiles in London, Paris, Berlin and Vienna and that in 11 months of 1912, 201 persons met death in New York City through the same means. Carried out for the full year, the estimated casualties by automobile in New York City will be about 220.

French Exports Increase $8,000,000

Paris, Nov. 23—For the first 10 months of the present year France exported automobiles to the value of $34,709,280, compared with $26,443,800 for the corresponding period of the preceding year. Increased business was done with all nations with the exception of five—Italy, Turkey, Russia, Austria and Switzerland.

The total value of foreign cars brought into France is $2,245,800. America is responsible for practically the whole of the increased imports. The official returns for the export of automobiles from France for the first 10 months of 1912 are as follows:

Country	1911	1912
Great Britain	$8,591,880	$9,537,600
Belgium	4,981,980	7,966,140
Algeria	1,906,980	3,052,980
Germany	2,204,040	2,698,560
Argentine	1,345,680	2,314,600
Brazil	972,900	1,716,960
U. S. A.	474,120	857,820
Spain	501,000	808,560
Switzerland	922,620	769,020
Italy	760,320	445,140
Russia	449,880	382,840
Austria	380,880	174,780
Turkey	284,400	120,660
Other countries	2,661,180	3,861,600
Total	$26,443,800	$34,709,280

Exports Take Another Big Jump

Washington, D. C., Dec. 2—According to a preliminary report of the bureau of Commerce and Labor, exports of automobiles and parts for October amounted to $1,583,812 and for the first 10 months of the calendar year, $19,836,111. The comparison between 1912 and 1911 is as follows:

Exports	October	10 months
1911	$1,043,093	$12,608,127
1912	1,583,812	19,836,111

Imports during October included seventy-eight automobiles valued at $170,410.

Northway Bids High for Ohio Property

Officers of New Concern Offer Top Price for Assets of the Embarrassed Factory Plant

Court Orders Sale Consummated Upon Deposit of $30,000, Making the Full Settlement with Mortgage

CINCINNATI, O., Dec. 3—(*Special Telegram*)—That the Northway Motor Company, headed by Ralph Northway, formerly prominent in Detroit motor circles, will take over the $1,000,000 assets and property of the Ohio Motor Car Company at Carthage, was definitely settled today when Receiver Edward Schultz, of the Ohio Motor Car Company reported to Common Pleas Judge Cushing that the best bid received by him for the assets of the concern was that made by William Pabodie, of Hartwell, and Ralph Northway now of Wyoming, O., who offered $60,000 as a lump bid. They agreed to pay $5,000 cash down to bind the sale, and to give a $25,000 mortgage on the plant and $30,000 additional cash when the sale is ordered. Judge Cushing ordered that the sale be made and it will be confirmed as soon as the remaining $30,000 is deposited.

Pabodie and Northway represent the Northway Motor Company, recently incorporated under the laws of West Virginia, with a capital stock of $600,000, and it was for this company that the purchase was made. Mr. Pabodie stated today that the new company will manufacture motors, this being the main part of the company's industry, though it will continue the manufacture of the Ohio car, the automobile which was put out by the Ohio Motor Car Company. The plant, valued at nearly $1,000,000, controls 10 acres of ground, about 3 acres of which is now under buildings but the new company expects to have to increase the accommodations within a short time.

Mr. Pabodie stated that the company will start in as soon as the court matters are settled and that it already has some 8,000 orders on hand. Mr. Northway will be the president and general manager of the new concern.

CINCINNATI, O., Dec. 1—Cincinnati is to have a new company to manufacture automobiles. The Northway Motor Car Company, which was just recently incorporated in West Virginia, with a capital of $600,000 will begin to produce here about the middle of December. The Chamber of Commerce is now making an effort to find a suitable location for the company. It is said that if this cannot be accomplished, an entirely new structure will be erected. Ralph Northway, of Wyoming, O., formerly connected with a large automobile firm in Detroit, will be at the head of the corporation. W. D. Furste, Edward Deckebach, of Cincinnati; F. W. Enslow, of Huntington; William Pabodie, of Hartwell, O., and Ralph Northway are the incorporators.

It is planned to employ 200 men at the beginning. No name has been selected for the car. At first it was rumored that they would take over the Ohio Motor Car Company at Carthage, O., but that concern seems to be getting along pretty well under the hands of a receiver, who, it is expected, has not very much longer to fill in at that position.

Electric Men Discuss Operative Costs

Several hundred electric vehicle men attended the meeting of the Electric Vehicle Association of America which was held at the Engineering Societies' Building, 29 West Thirty-ninth street, on Tuesday evening, November 26. Arthur Williams of the New York Edison Company, the new president of the association, presided for the first time in his new capacity.

The greater part of the evening was spent in a discussion of the papers which were read at the third annual convention held in Boston in October. In one of the papers dealing with the cost of electric vehicle operation it was stated that a 1,000-pound wagon effected a saving of $400 a year over a 1,000-pound horse-drawn vehicle, and that a 5-ton electric truck effected a saving of $1,100 a year over horse equipment capable of doing the same work.

President Arthur Williams stated that the New York Electric Vehicle Association will probably soon take its place as a section of the Electric Vehicle Association of America.

A standard design for an official garage sign was adopted. It consists of white letters reading "Electric Vehicle Charging" on a blue background, with the emblem of the association in the center. The sign is to be 4 feet long and 2 1-2 feet wide. It will be sent to garages everywhere in the United States which have electric vehicle charging stations.

Southern Roads Would Raise Rates

The meeting of the Southern Classification Committee will be held in Washington this week, and among the subjects that will be considered will be the contemplated changes in the classification of automobiles shipped over Southern railroads. The plan proposed by the railroads is to raise the classification of automobiles to double the present rates and to cut down the minimum car load requirements to half the present weights.

If adopted, the new rule would work a big hardship on the automobile shippers. As an illustration of its working it may be said that where, for instance, the rate applying between certain points is $1 per 100 pounds with a minimum weight per car load of 10,000, the cost of shipping an automobile weighing, say, 7,000 pounds would be $100. This is reckoned on the minimum weight at full tariff. If the classification shall be raised to double first-class, or, say, $2 per 100 pounds with a minimum weight requirement of 5,000 pounds, the shipper would have to pay $140. Of course, if the automobile weighed only 5,000 pounds or less the cost of shipment would be the same as it is at present.

Studebaker Sued on Flusher Patent

Suit has been entered in the United States District Court by the St. Louis Union Trust Company, as assignee of the Ottofy patent 795,059, covering a street flushing device which may be motor-propelled, against the Studebaker Corporation, charging infringement of the patent and asking for an injunction, accounting and damages.

The Ottofy patent has been adjudicated in an action in the Eighth Circuit of the United States Circuit Court of Appeals and held valid.

According to the bill of complaint, the defendant company has made a large number of street flushers which are alleged to infringe the patent in suit.

The Studebaker Corporation has until the January Rule Day to put in its appearance and its defense will develop later. The amount involved is said to be material.

Mercedes Radiator Patent Sustained

LONDON, Nov. 24—Justice Joyce has rendered an opinion in the suit brought on the Mercedes British patent 3235 covering a type of automobile radiator, against the Fiat Cab Company. The decision supported the patent. An injunction was granted by the court, but a stay was granted pending application for appeal. Under the British law it is customary when infringement has been found against a defendant to have the decree so framed that the infringing devices must be yielded up for destruction. In this case the Fiat Cab Company has several thousand cabs in service. The order of destruction has been stayed along with the injunction.

A. A. A. Is Flourishing

All Bills Paid and $3,293 in Treasury—Enos Succeeds Hooper as President —Chairmen Appointed

Rincon Road Opened by Automobile Run—H. W. DuPuy President of Pennsylvania Rubber Company

CHICAGO, ILL., Dec. 3—The annual meeting of the American Automobile Association, held for the first time in many years in the West, was interesting which was marked by only one fight—the Ohio clash. It also saw the retirement of Robert P. Hooper, of Philadelphia, as president, and the installation of Laurens Enos, of Buffalo. The national organization was shown to be in a flourishing condition, with $3,293 in the treasury and all bills paid, while the good roads cause was given the expected boost.

When William Schimpf, chairman of the contest board, took hold of the office there was a deficit, but he was able to turn over $5,000 to the treasury, report all bills paid and a small surplus in his bank. The board granted 132 sanctions. Twenty more tracks than ever before were licensed and the number of meets held during 1912 has been a record-breaker. There were ninety-four. In 1911 there were only fifty-two and in 1910 seventy-two. Nineteen of the 1912 dirt track meets were on 1-mile tracks and twenty-two on 1-2-mile ovals.

Not one fatality occurred at dirt track meets sanctioned by the national organization. While a few drivers have been injured, none was seriously hurt, while the records show that not a spectator was injured during the year.

The contest board took in $13,225 in sanction fees; $1,140 was collected in drivers' licenses; $100 was paid for stock car certificates and $320 was paid over for track licenses. The expenses of the board amounted to $8,170.

Chairman Batchelder, of the executive committee, made a brief report in which he told how the association now has 451 clubs allied with it, 148 more than the A. A. A. had a year ago. There are forty-four active state associations.

The Ohio Automobile Federation desired to be recognized as a state association, whereas the Ohio State Automobile Association already has the franchise. The Ohio State Automobile Association was opposed to the recognition of the federation, but the matter never came to a vote.

The new officers are as follows: President, Laurens Enos, Buffalo; first vice-president, John A. Wilson, Pennsylvania; second vice-president, Dr. H. M. Rowe, Maryland; third vice-president, R. W. Smith, Colorado; fourth vice-president, F. L. Baker, California; fifth vice-president, Asa Maine, Minnesota; secretary, J. N. Brooks, Connecticut; treasurer, H. A. Bonnell, New Jersey; chairman executive committee, A. G. Batchelder, New York.

It was decided to open a branch headquarters in Washington.

There was a lively fight for the next annual meeting, participated in by Buffalo, Texas and Virginia. The last named won out and the next session will be held in Richmond.

CHICAGO, ILL., Dec. 3—(*Special Telegram*)—At the meeting of the new executive committee today, President Enos announced the reappointment of the following chairmen; Contest, William Schimp; Good Roads, George C. Diehl; Touring, Howard Longstreth; Legislative, Charles T. Terry.

Tourists Pour Over Rincon Road

SANTA BARBARA, Nov. 25—The opening run over the Rincon sea-level road, which shortens the distance between this city and Los Angeles 9 miles and overcomes the Casitas pass, exceeded all expectations.

More than 150 automobiles made the 100-mile trip from the southern city, and it was estimated that more than 500 cars were driven to the Rincon yesterday, when 2,000 persons enjoyed an old-fashioned Spanish barbecue, provided by the Santa Barbara chamber of commerce.

The chamber of commerce committee in charge of the celebration was treated to its first surprise Saturday evening. It was predicted that not more than 100 cars would come north, but when a check was made at the Potter and Arlington hotels late at night, it was found that more than 150 had made the trip, carrying nearly 600 persons, thus breaking all state records for a run of the century distance.

The cars from the South all bore pennants, "Santa Barbara Rincon Run."

The visitors remained here over night, journeying southward again the following morning.

DuPuy Heads Pennsylvania Rubber

At the recent annual meeting of the Pennsylvania Rubber Company, Herbert DuPuy retired from the presidency in favor of H. Wilfred DuPuy, still continuing as treasurer of the company. The new office of chairman of the board was created, to which the retiring president was elected. Re-elected to continue in their same offices as formerly were: Charles M. DuPuy, vice-president; Seneca G. Lewis, general manager; George W. Shiveley, secretary; Charles G. Morrill, assistant treasurer.

Herbert DuPuy for some time past has been unable to take an active part in the management of the company on account of his increased responsibilities as chairman of the Board of Directors of the Crucible Steel Company of America.

Contracts with distributors now in hand assure an increase for the year of 100 per cent. over the business of 1911. The entire production at prevailing capacity is already sold for the ensuing year.

Dealers Order Charter Application

Application for a charter for the Motor Dealers' Contest Association, of New York, will be made immediately as the result of a meeting of the members of that organization on Tuesday. A temporary board of directors was chosen consisting of fifteen with J. C. Wetmore at the head. A general meeting of the association will be held December 13 at the Elks' Club at which the program for the annual meeting in January will be outlined.

Madison Square Garden, the scene of many a circus sensation, has added one more to its list. Automobile polo is the latest, and as a spectacular feature it is a distinct success. The efforts of Messrs. Hankinson and Marine, the promoters, brought together a crowd of 6,000 on the first night and it is predicted that the game will grow in popularity because of its thrilling features.

Cars parked at Rincon Point on the day of opening the road

Elgin Races Next August

This Year's Compact Between Elgin Road Race Association and Chicago Automobile Club To Be Continued

Limit of 450 Inches To Be Adopted—Much Business Transacted at Grand Rapids Show

CHICAGO, ILL., Nov. 30—Announcement is made that the Elgin road races will be run in 1913 and that the compact entered into this year by the Elgin Automobile Road Race Association and the Chicago Automobile Club will be continued. The meet will take place the latter part of August as usual and it will be marked by the adoption of the 450-inch limit, an idea originating at Indianapolis and intended to encourage the competition of American manufacturers.

The 1913 plans were discussed last Tuesday night when the Elginites gave a dinner to the members of the contest committee of the Chicago Automobile Club. It was agreed that the partnership be continued and the prospects were declared to be rosy. An innovation decided upon was to have only one race each day instead of two or three as has been customary. The first day will be given over to a non-stock race for cars 300 cubic inches and under, while the second day the one event will be for cars 450 cubic inches and under. The promoters have decided to make the distance in both races the same—about 300 miles—in order that comparisons may be drawn as to the relative speed abilities of the two classes. Heretofore it has been customary to hold the small cars down to short distances.

Private owners are to be encouraged to enter and with this idea in mind there will be a special trophy offered. B. C. Patterson, who tried hard to import the Peugeot team last summer, has pledged himself to make an entry. It is thought he has in mind trying for an English Sunbeam.

The meet will mark the re-entry into competition of a famous trophy which has been on the shelf since 1910—the Cobe cup. Ira M. Cobe, president of the Chicago Automobile Club, has agreed to turn the trophy over for the Elgin meet, provided the name be changed. Therefore, it is to be called the Chicago Automobile Club cup and it probably will be offered in the first day's race. It is hoped to have the Elgin National for the second day, provided an agreement can be made with the Chicago Motor Club, which holds the deed of gift.

Simplex Sets New Track Mark

RICHMOND, VA., Nov. 30—The raising of the "outlaw" ban on the mile circular dirt track of the Virginia State Fair Grounds, where today and yesterday, under the sanction of the American Automobile Association, the Richmond Automobile Club conducted a professional automobile meet: the lowering of the track record on the two successive days by Louis Disbrow, driving a Simplex, and a Kline Kar, driven by William Morton, flying the track twice in one afternoon while traveling at 50 miles an hour without other damage than ripping away tires, were features of Richmond's first automobile meet in which drivers of national and international reputation competed.

Big Sales at Grand Rapids Show

GRAND RAPIDS, MICH., Nov. 30—With an attendance record of 30,000 marked up to its credit during its 4 days and 5 evenings run, Grand Rapids' fourth annual automobile show ended most happily tonight.

In interest, attendance, value and variety of exhibits, and in everything but number of sales direct to ultimate consumers the show far eclipsed its three local predecessors. Upwards of eighty lines in 140 odd models, all represented by local dealers, were shown on the floors of the exhibit space, while everything in the line of accessories was shown, beside all motorcycles sold in this market.

The buying trend noticeable seemed heavily toward the medium and higher grades of cars. The Cadillac and Rambler lines, strongly represented, did heavy business. Several sales of $5,000 cars were effected, these including Packards, Kissels and Whites. The best single sale was of a White big six for $5,225. The Overland company exhibit, including every model of that line, the Marmon, Federal truck and Standard Electric, was turned over to the sub-agents of that company, twenty-four of whom were in almost constant attendance receiving their prospects.

Road Builders Meet in Cincinnati

CINCINNATI, O., Dec. 2—The ninth annual convention of the American Road Builders' Association and the third American Road Congress will be held here at Music Hall starting Tuesday, December 3, and running to Friday. Men from all parts of the country interested in the good roads movement will attend. The program which has been mapped out is extensive.

A special feature of the convention will be a big entertainment given in honor of the visitors at the Business Men's Club, December 4. It is expected that there will be an attendance of between 1,500 and 2,000. Addresses of welcome will be made by Congressman-elect Stanley Bowdle, by Mayor Hunt on behalf of the city; by Prosecuting-Attorney Pogue, on behalf of Hamilton County, and by President Walter Draper, on behalf of the Chamber of Commerce.

Machine Tool Show Definitely Fixed

The project of holding an exhibit of machine tools in connection with the annual New York show has been definitely settled. The exhibition will be held as a portion of the part two period, beginning January 20. Assurances of co-operation on the part of the Machine Tool Builders' Association as a body and also from individual members representing large companies have been received and a large and varied exhibit has been promised.

THE KELLS MOTOR RADIATOR COMPANY, capitalized at $650,000, has been incorporated to manufacture and deal in automobile radiators and motors. The incorporators are H. R. Bingham and A. F. Garbe of New York and C. A. Cole of Hackensack. The company is closely related to the W. J. Kells Manufacturing Company, of New York.

Simplified Handling of High-Speed Steel Problems Developed in Large Shops of Parisian School of Pyrology—The Use of Compensated Modern Planimeters for the Testing of Motors in Experimental Departments of Industry

TEMPERING and Selection of High-Speed Steel—The method developed by Taylor and White for tempering high-speed steel still remains the best devised for rough-turning and planing of mild, medium and hard steels. It consists in the following operations: (1) Slow heating in furnace to 800 deg. C., (2) rapid heating in furnace or forge fire to near the fusion point, (3) dipping of tool in a lead bath of 640 deg. C., (4) cooling—slow or rapid—from 640 deg. to atmospheric temperature, (5) annealing the tool in lead bath of 640 deg. (6) cooling—slow or rapid, at option—from 640 deg. to atmospheric temperature, (5) annealing the tool in lead bath of 640 deg., (6) more or less deformed and deteriorated by oxidation, and it is necessary to grind away several tenths of a millimeter to get to the sound metal.

For this reason this method is not so well adapted for drills, half-rounds, taps and milling-cutters in which the exact form of the cutting edge should be protected against the effects of oxidation, which become marked when the metal is exposed to the air at above 900 deg. C. At the Central School of Pyrology in Paris it has been found preferable to heat this class of tools in a bath of barium salt kept fused at a constant heat by means of a tri-phase electric current, and the following method for treatment of the tools has been developed:

(1) The tool is heated slowly to about 600 deg. in one muffle oven and then to about 900 deg. in a second muffle oven. To avoid oxidation in these ovens, pieces of incandescent charcoal are placed at the entrance of each of the muffles.

(2) When taken from the 900 deg. muffle the tool is suspended by means of tongs above the chloride of barium bath with only that part of the tool which is to be hardened immersed in the bath. The temperature of the bath is measured with a Féry pyrometric telescope and is maintained constant, with a tolerance of plus-minus 10 deg. C., by means of a rheostat placed in the inductor field of the generator used for producing the tri-phase current. The tool is left in the bath until it has taken the temperature of it.

(3) When leaving the chloride bath the tool is immediately plunged into a lead bath of 640 deg. and is kept there till it has reached the same temperature.

(4) Thereafter the tool is thrown into a trough with oil where it is cooled slowly to atmospheric temperature.

(5) Annealing, if there is occasion for it, is obtained by placing the tools in a muffle oven maintained at close to 600 deg. C., and white-hot charcoal is again placed at the entrance to obviate oxidation.

(6) Thereafter the tools are cooled in oil.

This method is modified in the case of tools intended for working upon tool steel, chilled cast iron or 25 per cent. nickel steel, for which work the temper produced by the method is too soft. For this class of work the cutting edge is quenched in oil, and annealing is omitted.

For work on brass and similar soft metals the method is also modified, as these metals are worked at a speed sometimes exceeding 100 meters per minute and the slightest hitch between the tool and the work causes the breakage of the former if it has received a too-high temper. Tools for this class of work are air-hardened. When the tool is taken out of the barium bath the tongs which hold it are hung above an air current produced by a blower. This modified method, which would oxidize completely a tool heated in a furnace, does not in the least deteriorate a tool heated in a salt bath as it is protected from oxidation by the layer of chloride which covers it. After the air-cooling the tool is annealed at a heat ranging toward 600 degrees C., as by the ordinary process, and is cooled in oil.

DETAILS AT VARIOUS STEPS OF THE PROCESS

It is not necessary to preheat all work before plunging it into the chloride bath. Practice shows that small tools of 5 millimeters thickness or less may be plunged into it directly. Only, they should be withdrawn three or four times, so as to make them take the heat more slowly. For pieces thicker than 5 millimeters it is important to have two muffle ovens, one heated up to 600 and the other up to 900 deg. C., so as to render the tool's absorption of heat gradual. It is, in fact, during the preliminary heating that large pieces warp before hardening. The pieces should not be taken from the first oven till they have reached 600 degrees, nor from the second to the chloride bath till they have reached 900 degrees.

The chloride of barium bath should hold about 3 liters and be about 200 millimeters (8 inches) deep. The container should be hollowed out of a refractory stone capable of withstanding the high temperature. To start the bath, the cavity of the container is brought to red heat by means of a gas flame. While this is being done, the chloride of barium is placed in a refractory crucible and is melted in a furnace. When fused it is poured rapidly into the red-hot container and the tri-phase current is at the same time turned on. Thereafter the temperature rises rapidly and when it has reached the degree wanted for the steel under treatment the rheostat is adjusted to maintain the temperature constant. When the work on hand is done, the bath is tipped into the refractory crucible, and the container is cleaned with an iron scraper to remove all detrition.

The Féry pyrometric telescope is permanently installed above and to the left of the bath. The galvanometer which is connected with the telescope by a double wire is placed in full daylight, so that the displacements of the hand may be easily and accurately observed.

The following method is used for determining the most favorable temperature for hardening in each case. A piece of high-speed steel about 3 millimeters thick is shaped as a half-round at one end with a very sharp thin edge and this is immersed in the barium bath for at least 3 minutes and is then quenched rapidly in water to dissolve the chloride. If the edge has retained its sharp angles, the temperature of the bath is raised 20 degrees, and the experiment is repeated. After a certain number of trials one finds in this manner the temperature at which the cutting edge begins to melt and which is designated as the fusion temperature of the steel in question. The number of degrees indicated by the pyrometer as corresponding to this temperature varies with different instruments but remains constant for the same instrument.

So as to be sure of not injuring any tool the heat of the bath is kept 50 degrees below the fusion temperature, and all tools are raised to this heat whether they are to be tempered in air, lead or oil.

The tools should remain from 2 to 5 minutes in the chloride bath, according to their size. In order to be able to temper several tools at the same time a number of wires are strung horizontally above the bath, one above the other, and the tongs which hold a tool are hung from one wire or another according to the length of the tool, so that in each case only the part to be hardened dips into the bath. In this manner four jobs may be done at the same time. When one tool is ready to be tempered it is withdrawn from the bath and replaced by another. Tempering two tools per minute is a speed easily reached, and this can be increased when several tools of the same kind are hung from the same tongs, which is the usual practice for small tools.

When the tools have been tempered and annealed they are covered again with a layer of barium chloride, and when the tool is to be used this layer may be easily removed by leaving the tool for some time in boiling water.

GETTING A TRI-PHASE CURRENT FROM SIMPLE DYNAMO

At a place like the Central School of Pyrology in Paris where several hundreds of machine tools are in use, the wear of tools is so much reduced by the use of high-speed steel that regrinding and tempering is required only once a week. Under these conditions it is not necessary to install a special tri-phase current dynamo. One of the generators working with continuous current, either for lighting or for power transmission purposes, will furnish the required current while the hardening is going on. The 220-volt current passes through a transformer which reduces it to 15 volts.

To maintain a 3-liter bath at the fusion temperature for high-speed steel, a current of 300 amperes for each phase is required.

TESTING HIGH-SPEED STEEL FOR ACCEPTANCE OR REJECTION

Most of the many high-speed steels in the market give good results for work in soft and medium hard steels; a smaller number work well with hard steels, but only a few choice marks give satisfactory results for crucible alloy steels, chilled cast iron and 25 per cent. nickel steel. In order to avoid stocking up with high-speed steels which are not suitable for all kinds of work, the Central School of Pyrology has gone into considerable research work on the subject and has arrived at a certain testing method which is simple, inexpensive and in the main satisfactory. The proceeding is as follows:

Select from each shipment a certain number of bars. Cut from each of these a piece of steel from which there can be forged or machined a piece about 150 millimeters long by 12 millimeters square. Harden these pieces as stated in the foregoing and mount them to work in a tool-holder of a filing machine. Determine the average weight of shavings from 25 per cent. nickel-steel obtained between two successive mountings. Compare this weight with that which a good high-speed steel should give, and accept or reject in accordance with the result of this comparison.

In order that this test may be justly decisive it is important that the conditions should always be identical. The rules adopted in this respect at the Central School are as follows:

The tool is mounted as a simple planing tool. All forms are calipered to measurements, so that the tools always have the same cutting angle, rake and clearance, as well as the same rounding of the cutting part.

The tool-holder may be of any form, provided only that the tool when placed in it always extends in the same direction with relation to the axis of the holder.

Any filing machine of medium power and in good condition may be employed by modifying, as described below, the control rod for the tool-holder slide. This modification, which can be applied to all filing machines, has a double purpose; namely, (1) to render the charge of the tool less brutal and (2) to permit stopping the test when the tools have reached the same degree of wear.

The modification consists in making the control rod in two pieces telescoping one into the other and united by several pairs of washers. When the cutting edge reaches contact with the work-piece the washers are compressed gradually, allowing the tool to take hold without violence. The compression of the washers increases with the wear of the tool. An index hand, the point of which moves over a graduated sector, amplifies and measures the compression of the washers. Each test is stopped when the hand reaches a certain mark on the scale.

The average linear speed of the tool during the test work is close to 12 meters per minute. The depth of the cut is 1 millimeter. To make sure of it, an index hand is secured upon the movable part of the tool-holder moving over a millimeter scale on the head of the slide-rest. The feed is approximately 1-4 of a millimeter which corresponds to one tooth of the gear pinion controlling the displacement of the tool-stock. The test is stopped when the index hand during the work shows a high compression of the washers by brusque oscillations beyond the stop-mark on the graduated scale.

Evidently other rules may be substituted for these, the main requirement being the safeguarding of an equality of the conditions under which the tests are made.

The nickel-steel used for the tests should analyze between 20 and 25 per cent. of nickel, and untreated test pieces of it should give at least the following figures for tensile strength: Elastic limit average 35 kilograms per square centimeter, minimum 32; ultimate strength average 95, minimum 90; elongation average 35, minimum 32.

Tests made under these conditions with a good high-speed steel, hardened as described, give regularly close to 1 kilogram of shavings between two successive adjustments of the tool. To obtain a clear showing, it is necessary to make at least three consecutive tests with the same tool, remounting it several times, and to take the average of the results obtained.

This testing method is much simpler than that defined by Taylor but does not serve the same purpose. Taylor sought to determine the best method of tempering, with a view to obtaining the highest efficiency for roughing tools. For this purpose his method remains the best.

The method here outlined has for its object to make sure that the high-speed steel put in stock is of very good quality and can give good results in work with the most difficult metals and alloys.—From article by P. Gorgey, captain of artillery, instructor at the Central School of Pyrology, in *Technique Moderne and Revue Pratique des Industries Métallurgiques*, September and October.

CORRECTING and Utilizing Planimeter Readings—In the measure as competition in the manufacture of automobiles and motors becomes keener and the necessity becomes more apparent for combining quality with quantity in production, the means for ascertaining just what a motor or a carbureter, or the two in combination, will do throughout their range of adjustments are getting to be more and more a subject for serious practical consideration in the experimental departments of manufacturers. Dynamometer tests are required to be verified by diagrams obtained from manographs or indicators—and obversely—and all expedients for simplifying these testing methods, and at the same time removing the causes of possible errors in their application by employes of average attainments, begin to spell dollars by the thousands, in as much as their use or non-use eventually comes to mean a reputation or a lack of reputation for that freedom from little nettling flaws and troubles in the operation of a car which the public appreciates above all else, once it has been demonstrated to be within reach through the painstaking work of the technical leaders in the industry. To reconcile such painstaking work, which is largely in the nature of applied science, with the requirements of economical production is a task to which European and perhaps especially German engineers are now devoting a large portion of their energy. The Sternol oil-testing machine (mentioned in THE AUTOMOBILE of January 11), machines for verifying the cut and efficiency of gear teeth (THE AUTOMOBILE of Dec. 21, 1911), the minimeter devices (THE AUTOMOBILE of May 2), Brinell and other testing methods (THE AUTOMOBILE of Feb. 29, March 14 and July 4), machines for polishing test pieces (THE AUTOMOBILE of April 4), the accelerometer (THE AUTOMOBILE of October 10), other transmission dynamometers (THE AUTOMOBILE of October 24) and the micro-indicator (THE AUTOMOBILE of November 28) exemplify this movement by which Europe expects to render mass-production methods technicaly as well as economically satisfactory.

THE PRINCIPLE OF ORDINARY PLANIMETERS

The verification of planimeter readings comes in the same line of efforts, because the measurement of the area of an indicator diagram, or rather the measurement of many such diagrams, constitutes an indispensable method for ascertaining and recording the inner workings of a motor. The planimeter was invented in 1854 by Jacob Amsler and his construction has not been improved till lately when the compensating planimeter was introduced, by which errors due to wear or flaws of the instrument may be easily corrected. The ordinary planimeter is composed of two rigid arms of which one carries the angle-pole or fixed point P, Fig. 1, and the other the tracer T. A universal joint permits all relative displacements of these arms, and a roller M placed at the opposite end of the tracer rests on the level and either rolls or slides on the paper in following the movements of the tracer. To make use of the instrument it is only necessary to stick the pole pin into the paper at one point and to follow the contour of the area with the tracer. The revolutions of the roller, as recorded on a scale, then constitute a measurement of the area. Mathematically it can be proved, in fact, that the area of any figure whose perimeter has been followed by the tracer equals the area of a rectangle whose base is the length of the tracer arm and whose height is the distance travelled by a point on the circumference of the roller.

If L is the tracer arm, M the circumference of the roller, n the number of its revolutions and nM consequently the distance travelled, the area S equals L multiplied by nM, and as L and M are constant factors, at any one adjustment of the tracer arm, this can be written: S equals Kn.

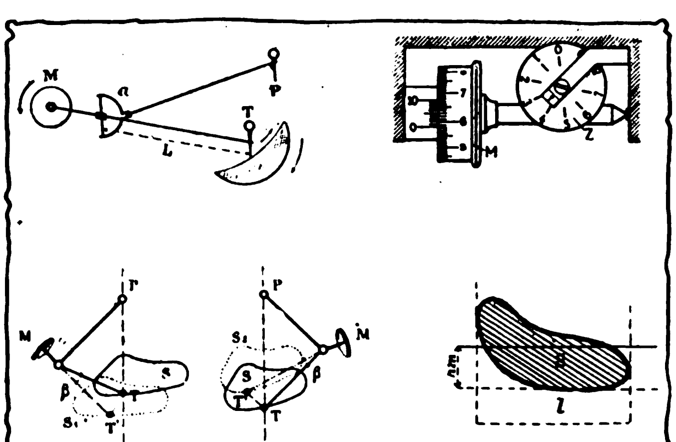
In practice, the unit of measurement is not the surface ML, but a 1/1000 part thereof. It is this unit of the graduate scale which we call K, and n is the number of K-movements made by the roller. The absolute value of K depends, then, on the length of the tracer arm, which in turn is determined by the point at which the joint a is attached to this arm. The instrument has therefore on this arm marks which give the value of K according to the point of attachment of a. In most instruments the value of K varies between 2 and 10 square mm.

K being fixed, only n remains to be measured, and this is done by a watchwork of the type indicated in Fig. 2. The tracing is always done "with the clock." Thus, if the watchwork showed, for example, 3,500 at the beginning of the tracing and 3,584 at the end of it, and the value of K is 10 square millimeters, the area traced is 10 × 84, or 840 square millimeters.

The accuracy of this reading depends, however, essentially upon the parallelism between the axis of the roller and the mathematical tracer arm, which is not identical with the visible tracer arm but is a straight line from the center of joint a to the point of the tracing stylus. If this parallelism is not accurately materialized in the instrument—and rough handling may easily disturb it, even in good instruments—all the area measurements will be more or less faulty.

That non-parallelism has this effect is easily understood. Assume that the two parts of Fig. 3 have been traced with an instrument in which the deviation from parallelism is represented by the angle beta (β). The roller now does not measure the area of the surface S which has been circumscribed by the material tracer T but that of a surface S_1 and S_2 which would be the one followed by a hypothetical tracer T_1 situated exactly in the prolongation of the roller axis. By placing the planimeter in two symmetrical position around the same pole, as instanced in Fig. 3, and outlining S_1 and S_2, it is readily proved that S equals S_1 plus S_2, divided by 2; that is, as the same error is committed in one case to the positive side and in the other to the negative side, it disappears when the mean of the two measurements is taken. The error is "compensated."

On this principle, in order to rectify a planimeter, one should make it trace a perfectly known area, preferably in two symmetrical positions from the same pole, and either determine the exact length of the arm L at which K will correspond to reality or else correct the obliquity of the instrument by means of a compensation-device adjustable by a screw. These corrections cannot be made, however, with ordinary planimeters. A special construction is necessary to permit the symmetrical reversal of the instrument, and a special screw for adjusting the axis of the roller is required. In practice such compensating devices are quite necessary, as the errors in the use of a worm planimeter may be relatively large and the results of elaborate tests of motors often depend upon the measurements taken of a few diagrams of small size and produced at different times. In the experiments of the author the Ott compensating planimeter is used which he considers the most modern and perfect of the instruments actually in the market.



Figs. 1, 2, 3 and 4—Illustrating the utilization of compensated planimeters

FINDING THE MEAN INDICATED PRESSURE

Some hints with regard to the practical use of planimeters may not be superfluous. The object of measuring the area of an indicator or manograph diagram is to determine the average height h_m of the indicator spring displacement from which the mean indicated piston pressure of the motor is computed. By two tangents to the diagram, as in Fig. 4, its length l is determined; let k be the unit of area corresponding to the adjustment of the instrument, n the distance traveled as marked in figures on the scale. The area S equals nk. We then have:

$$(1) \qquad h_m = \frac{S}{l} = \frac{nk}{l}.$$

FINDING HORSEPOWER BY THE PLANIMETER

If one has a large number of diagrams to measure, all taken from the same motor, precious time may be gained by making the planimeter give directly the indicated horsepower.

Those Counterspring

Forrest R. Jones Scores Against Editorial Opponent in Mathematical Correctness of Counterspring Theory

But Opponent Maintains That the Bare Theory Though Correct Is Misleading in Practice Unless It Is Amplified

IT was the mathematically supported contention, in an article by A. Contet, which was translated in THE AUTOMOBILE of Sept. 26, that the addition of a counterspring to an ordinary vehicle spring results in a compound spring which is less flexible than the original vehicle spring, although the vehicle load is supported by the latter alone, and it was stated by Mr. Contet that, for this reason it is common practice, whenever a counterspring is added, to remove one of the leaves of the original spring, so as not to impair the flexibility. It was also noted that springs doctored in this manner show signs of weakness in practice. The correctness of the theory was doubted in an editorial note, contesting the correctness of the mathematics on which it was based. Then a communication was received from Mr. Forrest R. Jones, upholding Mr. Contet's theory and giving new mathematical proof for its correctness, and this was published in THE AUTOMOBILE of Oct. 31 Concurrently therewith an editorial note again gave expression to dissent on the ground of an alleged fault in the application of the mathematics.

Promptly, under date of Oct. 8, another communication from Mr. Jones was received in which it is stated that "In Editor's note, Sept. 26 [should be Oct. 31], every sentence, as a whole, presents a statement that is in error, except the first sentence and the last paragraph. The old stumbling block of negative values seems to have tripped him." The communication also contains much additional matter tending to prove that the theory expounded by Mr. Contet and by Mr. Jones is truly correct, but the length of this additional reasoning and the fact that it merely confirms what had previously been set forth very adequately by Mr. Jones, and gives no new viewpoints on the practical importance of the theory, militate against its publication *in extenso* in this issue. The editorial commentator has seen the light. The theory and the mathematics are correct. The compound spring, in which the counterspring forms a part, IS less flexible than the simple spring from which it is built up. The object of discussion is strikingly attained in this admission.

Nevertheless the fact, as noted by Contet, that this theory leads to the practice of eliminating one of the leaves of the original spring, in order to restore the lost flexibility, shows that it is vicious and academic, unless the reason for the reduced flexibility is specially explained.

In reality the compound spring is less flexible than the original spring only because its construction involves the imposition of an extra load on the original spring, and because this extra load is not considered when the flexibility is calculated from the deflection caused by a given load. The compound spring is constitutionally deflected to start with, and this initial deflection is not counted. The reduction of flexibility is not of the same kind as that obtained by an extra leaf. On the contrary it is obtained by putting a load into the spring itself in the form of the counterspring's downward pressure, thereby adding to the burden of the original simple spring and weakening it proportionately. The amount of vehicle load which can be placed upon it with safety is reduced by the amount of the load which the counterspring imposes.

In the accompanying illustration, Fig. 1 shows the original spring R and the counterspring R_1, both unstressed. The supposition is that a stress of, say, 500 pounds is required to flex R_1 three inches and that the same stress will flex R only one inch. When the two springs are clipped together, as in Fig. 2, the open of R will thus be reduced from four to three inches, while the counterspring will be flexed three inches. Now, when the unloaded compound spring (Fig. 2) is put under load of 2000 pounds, acting solely at the eyes of R, it will assume the shape shown in Fig. 3, because in this position the counterspring has ceased to act and 2000 pounds will bend R four inches. Considered as a compound spring-unit it has undergone a deflection of only three inches, however, and this is the fact which is considered in the mathematical theory. The deflection of R shown in Fig. 2, which is one inch, is omitted from consideration, because it is not technically the result of a vehicle load. And thus it may be contended successfully that the compound spring is less flexible than the original spring R, since it is deflected only three inches under the same vehicle load which deflects the simple spring R four inches. A practical limitation to the mathematical theory is illustrated in Fig. 4, which represents the position of the compound spring under a load larger than 2000 pounds. In moving from the position of Fig. 3 to that of Fig. 4, the original flexibility of R has of course been restored, technically and otherwise, simply because every counterspring in practice has a limited range of action, which fact is unconsidered in the mathematical theory.

This leads to the only really important question in the whole matter, which is: How may countersprings be used to advantage? It is seen that they stiffen and at the same time weaken a spring. In order to obtain, then, the advantages which they may offer in the way of a brake on the rebound, it is required that the original spring should be stronger and more flexible than ordinarily necessary for its load. In other words the counterspring may be used as a moderator for an extraordinarily long, strong and flexible spring. Beyond the counterspring's range of action—under very severe shocks—the full advantage of the long spring's strength may then be enjoyed, while its excessive flexibility under ordinary conditions is reduced.

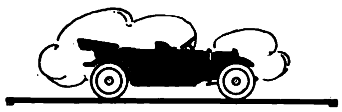
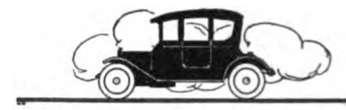
Coupé Body for Ford Runabout Chassis



Possible Combination of Two and Four-Passenger Design for Winter Travel



By George G. Mercer

THE body design here illustrated is made to fit the chassis of a Ford model T runabout. It is designed to occupy the same space as the runabout body, without disturbing the base or platform to which the gasoline tank, tool box and body are fastened. As with previous designs in this series, the original car is interfered with as little as possible so that the runabout body can be replaced on the return of warm weather without trouble or unnecessary expense. The change speed lever, being located in the center in this model, no alteration is necessary in this connection when adopting a closed body.

The Ford model T runabout has a wheelbase of 100 inches; the tires are 30 by 3 inches in front and 30 by 3.5 inches in the rear, the motor being 3.75 by 4 inches and as the manufacturers furnish a larger stock body than the one illustrated on the same chassis, the question of overloading need not be taken into consideration.

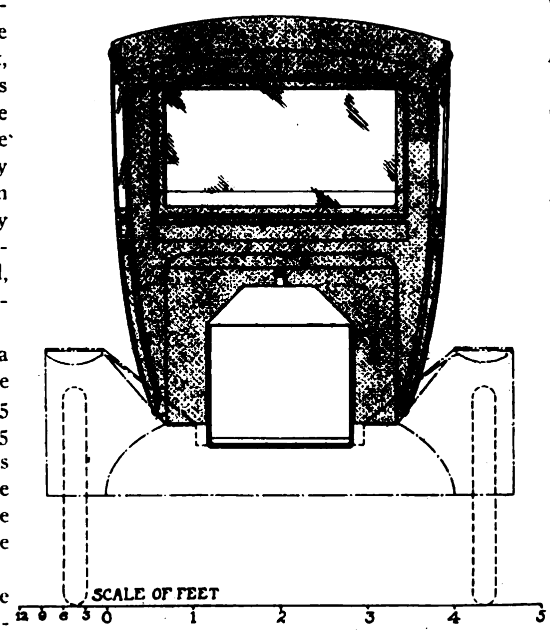


Fig. 1—Front view of Ford coupé design

Fig. 4 is the side elevation of the suggested winter body, having the general lines of a miniature brougham. This body can be mounted and secured to the platform that rests on the chassis frame, the door and the framing around the door being of greater width than the platform, so as to overhang a distance of 6 inches. The object of this straddle-wise mounting is to create a more balanced appearance in the car as a whole by having deeper doors. A dotted line carried across the body in this illustration shows the upper surface of the platform. Below this line the door is of course simply a dummy, so far as its use is concerned. In the rear view, Fig. 3, the relative positions of the door and the platform are more clearly shown. The pillar projects beyond the sides of the platform. The body is very light, weighing approximately 550 pounds.

From back to front, Fig. 4, measures 41 inches; the width of the door opening is 18 inches and the extreme width of the body, Fig. 2, is 46 inches. Notwithstanding these small exterior dimensions, those of the interior are fair proportions for two averaged sized persons. The size of the cushions, etc., are indicated on the three views, Figs. 2, 3 and 4. A considerable sweep is given to the line of the roof, Fig. 4, producing a lower general appearance without making the vehicle inconvenient in any way, as height is not necessary at either front or back. The windshield glass at the front is protected by a small leather bonnet stretched over a metal frame. Wood panels and framing are used throughout the design. The construction is identical with that used on horse drawn carriages and all framing is made as light as safety will permit. The windows of the doors and sides are made to lower for ventilation, while the rear pane is stationary. In order to obtain a rain visor, the front window is provided with hinges at its upper edge. Plain plate glass and mahogany frames are used for the windows. The cowl can be formed in either steel or aluminum. It is fastened to the back of the dash, rubber packing being inserted to prevent leaking. By not having to change the dash, the dash lamps remain undisturbed in position when the bodies are changed.

The most suitable colors for painting the body are the stock blue used on the runabout for the lower body panels, cowl and

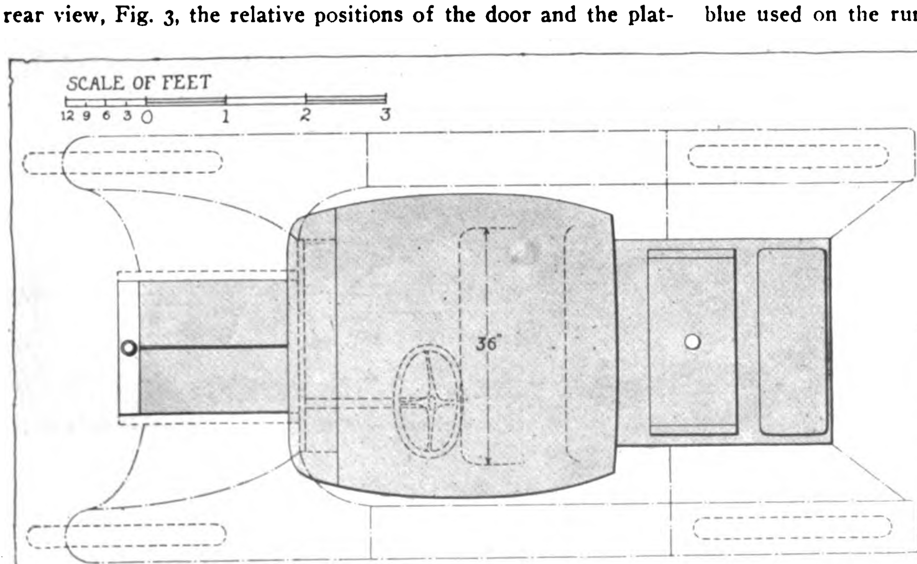

Fig. 2—Plan view of coupé suggested for Ford runabout

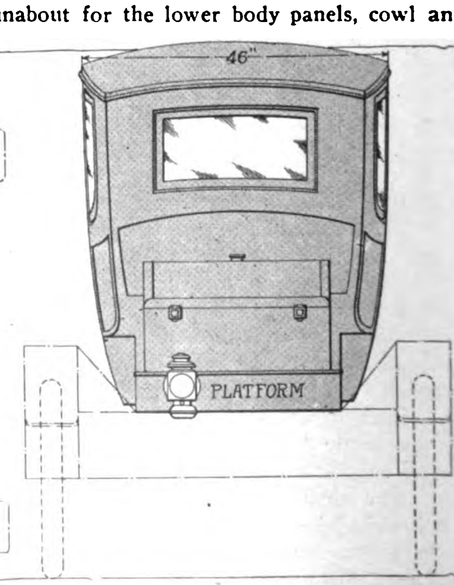

Fig. 3—Rear view of Ford coupé

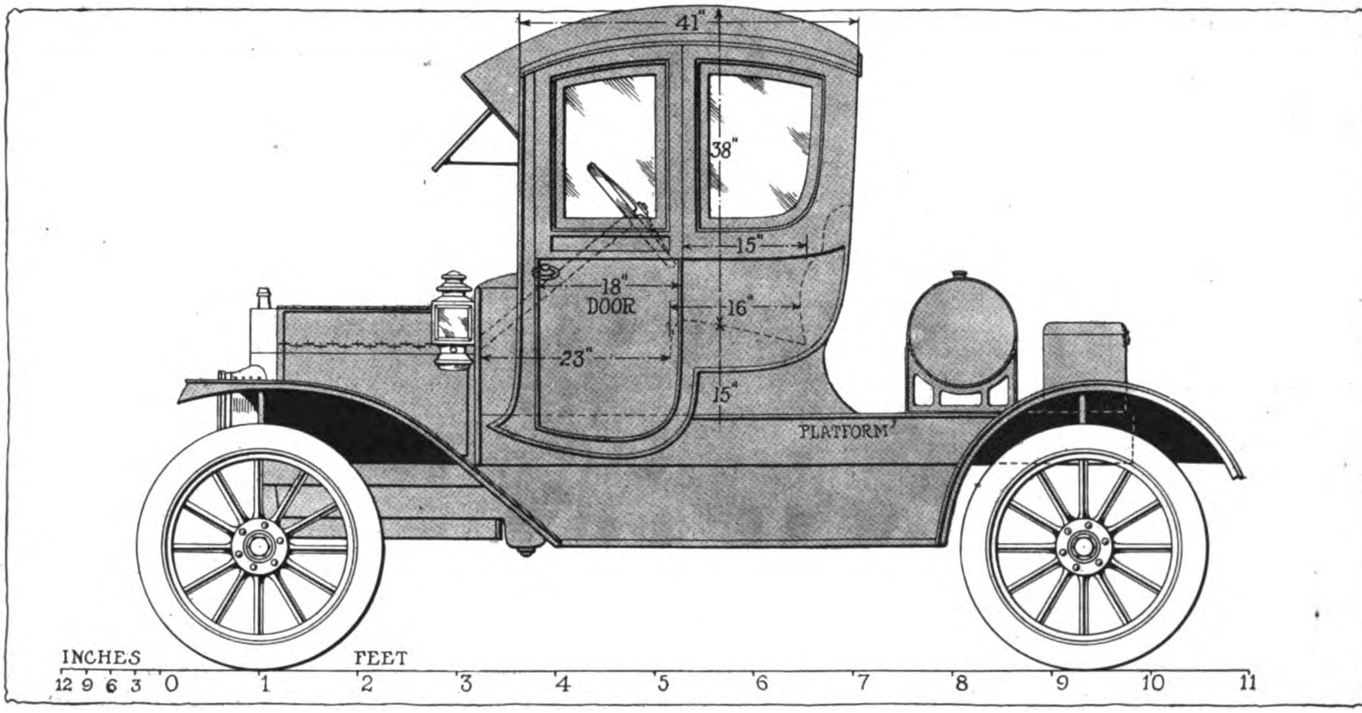

Fig. 4.—Side elevation of coupe body mounted on platform of Ford runabout

fore-body, with black mouldings, and black for the upper panels above the belt line and for the roof.

Leather may be used for the interior trimming. The material that is furnished in large skins as imitation morocco is very serviceable and as little liable to crack as the genuine article; in fact, it is a question if it is not a trifle more reliable in this respect. A suitable finish would be blue broadlace for binding on the doors, etc., blue carpet and blue silk curtains.

Inside, the appointments would be the customary silver-mounted electric dome light in the roof and very simple card and ash cases on the doors.

A further use to which the new body can be adapted is shown in Fig. 5, where it will be seen that the coupé body has been moved to the rear of the platform and a fore portion for the driving seat added. On general principles a combination body is not desirable, but in the present case, as there are no moving parts with hinges, all being easily and firmly attached to the platform no real objection can be raised. The fore-body is provided with side doors and a windshield is mounted on the cowl. A larger bonnet is fastened to the front of the body to protect the driving seat and from the front of this to the windshield is stretched a leather flap, that serves as a watershed and is also removable. Side curtains can be added that will entirely close the front when required. Leather trimming of the usual type would be found suitable for this part of the car.

The addition of this fore-body necessitates the removal of the gasoline tank and tool box from the rear and the placing of a tank under the front seat.

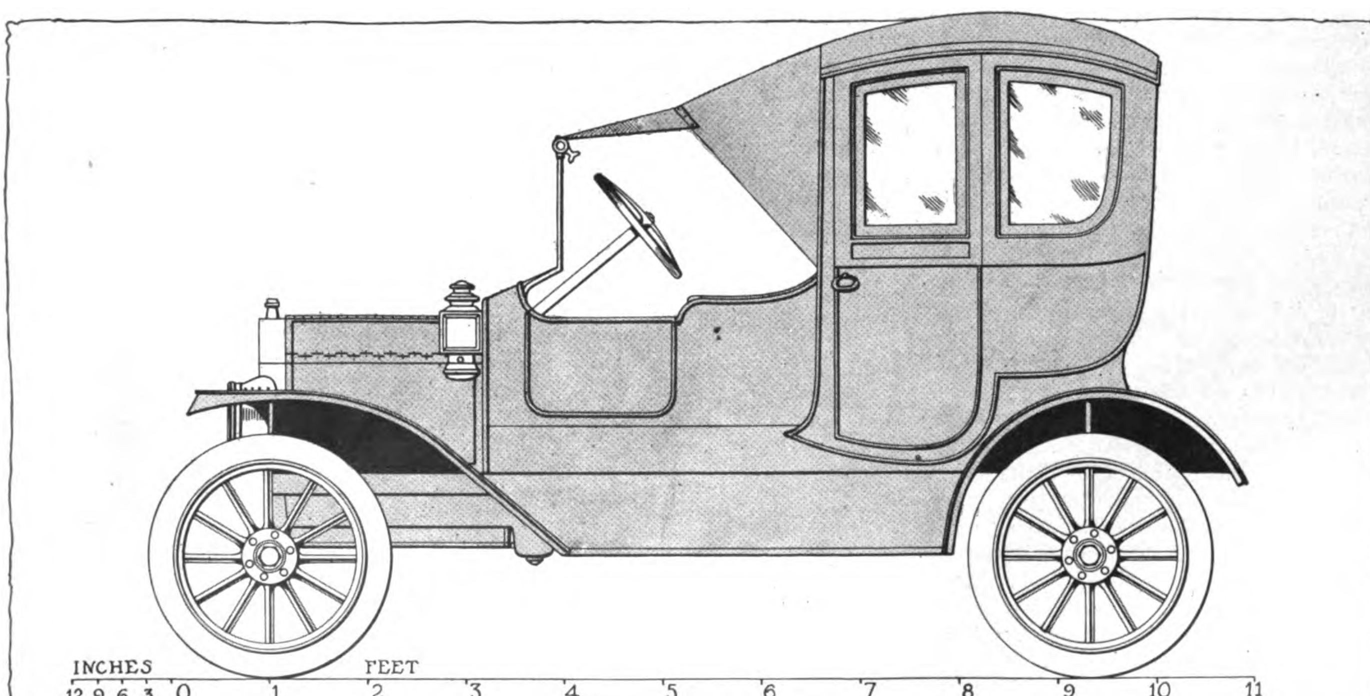

Fig. 5.—Same coupé body moved back on the chassis to permit of the addition of a fore-body

Gimbel Brothers' System of Delivery

How Ninety-five Freight Automobiles Serving 5,000,000 New Yorkers Are Handled Efficiently

Private Service Department of the Gotham Store Employs Fifty Men and Uses Ten Forms for Recording

MINIMUM standard cost of unit of work is the goal of modern industry and commerce. Forgetting for a moment that industry and commerce again serve a purpose, filling the needs of mankind, the attainment of that minimum cost of economic operation is the center toward which strive every man and woman who contribute to the work of the world. Every individual attempts to realize the condition maximum effect with minimum of effort in his or her personal work; so that, as soon as the interest of the individual actually becomes identified with that of the whole, a very high and efficient standard of the world's work may be a reasonable expectation.

At this moment, when the study of economic efficiency is but a babe and hardly past the embryonic stage, few people realize the importance of the problem outlined above. These people are generally those who see the differences of efficient and inefficient work, because they come in contact with huge bodies of labor, because upon their shoulders rest immense responsibilities, because through their hands streams the well-regulated current of the wealth of the planet. Little reflection is necessary to arrive at the conclusion that the processes adopted by these people in handling their work are the expression of supreme commercial intelligence at work today. They are, therefore, worthy of more than passing consideration of the progressive business man.

Delivery System for Stores

Department stores in large cities, which are the main centers of distribution, are today well ahead in respect of efficient operation. Much has been said about the concentration expended by store managers upon the increase of sales and the most advantageous methods of begetting these; yet, the transportation of the wares, after they are sold, is no less worthy of admiration. To carry it out, in the most profitable fashion, three things are necessary:

(A) Exact records must be kept of the goods shipped from the store;

(B) Exact records of the cost of delivering the goods sold must be kept;

(C) Conclusions drawn from the figures afforded by the above information must be used to devise ways and means to further reduce the cost of deliveries.

(A1) The records of the goods leaving the store are part of the store organization proper and are handled by the charging and shipping departments, who also arrange the outgoing packages, according to routes, so that the drivers may take the parcels out of bins and spaces assigned to them, individually, and distribute them over their delivery route. The charging and shipping records are, later on, checked against the delivery records of the drivers. From day to day, or from week to week, the company is thereby enabled to prepare digests of its business, as represented by the number of packages delivered. The results are the following values: packages delivered per day, week and month; packages delivered per wagon, per unit of time; average sales value of every package delivered.

Fig. 2—Repair tag with which cars are sent to the shop

(B1) The following items make up the cost records of delivery: Direct and indirect maintenance cost, incidental expenses and loss. This information is carefully prepared, giving attention to every item, referring to every car operated by the company. Thus an exact history of every car is kept on record. Besides, average costs of various items per car may be arrived at. These averages divided in the average work done by a car give average delivery costs. These represent the final result of cost-keeping, so far as records go.

(C1) It is left for experts in the various departments of the delivery work and the automobile operation to improve on the operating figures.

The proposition (B) forms the sole subject of this article. It is proposed to show in the following the manner in which the delivery work of one of the greatest stores of the world is carried out. This refers to the New York store of Gimbel Brothers, the Philadelphia and New York merchants. This corporation effects the delivery of wares sold in the Manhattan store through the service of 127 automobiles, of which ninety-five are kept in the main garage in West Twenty-fourth street. The rest are stationed partly at the 183rd street garage of the company, with the exception of several trucks operating solely in suburban fields. The fleet of the company is made up of eighty-nine electrics and thirty-eight gasoline trucks, the electrics taking care of city work only, while the gasoline trucks serve as transfer wagons to railroad depots and distributing centers of the company, about half a dozen of which are located in close proximity to New York.

The ninety-five automobiles stored at and operating from the Twenty-fourth street garage are served by fifty men, besides a driver and a helper for every truck. These fifty men are mechanics, repair shop men and garage hands. The system of using cars is as follows: All automobiles leave the garage at a specified time in the morning, starting for the store, where they are filled with packages to be delivered. As soon as a wagon has finished its route it returns to the store and is reloaded, time and again; in the evening it returns to the garage and the driver rings in his time on the clock as the working day is finished.

Delivery-record forms are ten in number. They cover every necessary point of information relating to the delivery itself, the maintenance of each car and the cost of both. The forms may be divided in three groups: (I) Time-record blanks, giving the distribution of the working times of the trucks. (II) Maintenance forms for recording gasoline or current, repair work and parts used and expended on every truck. (III) Cost-compiling forms which give the expenditures in dollars and cents, both for all machines and for every individual truck.

(I) The time of start and finish being recorded on a clock card which is kept at the garage, a form for the distribution of working time has been prepared, Fig. 4. This blank, 6 inches wide by 11.75 inches high, is printed black on tan paper. Each trip of every driver is recorded on this blank which is sent in the evening to the garage, where it forms, together with the clock card, an exact account of the driver's time for the day. The details of every trip appear on the delivery-and-receipt forms, not shown here.

(II) To keep the truck in running condition it requires fuel or current, lubricants, tires, as well as repair work and material which become necessary from time to time. The gasoline trucks draw for fuel upon the gasoline tank which is installed in the garage, and the fuel delivered to them is recorded on a duplicate roll of paper, such as used in many small stores. A copy of the record is kept in the garage and a duplicate given to the driver, who later on turns it over to the superintendent. In the case of electrics, a charging card, Fig. 1, is used every time a battery is charged. This card is 3 inches wide and 3.25 inches high, printed black on thin, white cardboard and ruled with blue lines. The degree of charging when the battery is turned over to the driver is recorded and a space for the odometer reading just before charging is allowed on the reverse side of the card.

Repair Forms Described

Repairs require a comparatively large number of records, due to the variable nature of this work, and following the example of up-to-date service departments, Gimbel Brothers in their garage have provided an elaborate cost-keeping system for this phase of their delivery organization. Repairs are undertaken either upon the request of the driver who notes a defect in his truck and brings it to the attention of the garage superintendent, or when the defect results in a breakdown in the street; likewise, if the truck meets with an accident. If the driver causes a repair to be taken up, he fills out the Motor Defect Card, Fig. 3, which affords space for ten items on one side, while the blank reverse side may be used if the remarks do not find space on the face side. This card is 7 inches high and 3.5 inches wide, printed black on thin tan cardboard. After the card is filled out, it is handed to the foreman on duty who represents the superintendent on the floor and who directs the necessary work to be done. If the truck, however, is disabled on the road, the driver telephones to the garage, and the message, which is taken in the office of the superintendent, is recorded on Emergency Call Card, Fig.

MOTOR DEFECT CARD.

INSTRUCTIONS: Drivers must report on this card, upon each return of car to Garage, all defects or other trouble with car occuring on date stated below, and, before leaving the premises hand same to Foreman on duty, using reverse side if necessary.

TIME CHECKING SHEET

EVERY EMPLOYEE in this Department will enter their NUMBER, NAME AND ACTUAL TIME of arrival in the Department in the morning and EACH TIME THEREAFTER they leave or arrive in the Department during the entire day. There are no exceptions to this rule.

GIMBEL BROTHERS.

WRITE PLAINLY

Number	NAME	IN	OUT	Were you late? Say YES or NO

Fig. 4—Time checking sheet for recording drivers' trips

6. The latter is 11 by 8.5 inches in size, printed black on tan paper and kept in the office of the superintendent. When a driver calls up, his name, the number of his truck, his locality at the time of trouble, the number of the telephone used by him and the help required are recorded in the proper spaces; furthermore, all particulars relating to the relief car sent to aid find space on this form. In a corner of the card the used materials and their actual cost are noted.

Emergency Work Anticipated

A car which meets with an accident is either put in working condition on the road or hauled in to be repaired. Whenever a truck undergoes a repair, a repair tag, Fig. 2, is filled out. This tag is 8 by 5 inches in size, printed on tan cardboard of medium thickness and is filled out by the foreman with the particular repair jobs required on the car. When the tag has been filled out, it is attached to the truck, which is turned in the repair shop by the foreman. There labor and material used in the repair work are recorded on suitable blank, as they are in service department. As a matter of fact, the repair department of the garage may be well referred to as a private service department. The time ticket, Fig. 10, is filled out by every man who works on a car, the order numbering identical with the job number appearing in Fig. 2. The work being finished, the ticket is turned over to the foreman, who O. K.'s it. Of course, time-clock cards are also used for all people employed in the garage. As to the material used for repairs, a requisition of the same size as the time ticket, namely, 7 by 4 inches, is used. This requisition, Fig. 9, like Fig. 8, is printed black on thin white paper. It is used for all material kept in the stock room, including lubricants, and the cost of everything taken out is recorded on the requisition. Before anything is delivered to a shop man or driver, the requisition must be signed by the foreman on duty. After the respective materials have been delivered, all requisitions are filed away in the stock room, to be delivered to the superintendent's office in the evening, after which the account of every car is charged with the supplies or repair parts used on it.

When a repair job is completed, all the time slips and material requisitions are put together and a digest of them is made, the record being laid down on the cost card, Fig. 8. Every time a repair is done, this happens, and the various repair cost cards thus obtained are secured by means of clips to the monthly operating-cost record, Figs. 5 and 7.

The cost card blanks, which are used for the recording of gasoline and current, respectively, tire, repair and incidental expenses, are shown in Figs. 5 and 7. Fig. 5 is a monthly operating-and-maintenance cost sheet, 16 by 10.5 inches, affording a line for every day in the month, upon which the following information is entered: The number of the driver operating the truck on each day, the number of the battery—in case of an electric—as well as the current used; in this space the amount of gasoline is recorded in case of a gas truck. These points give the operating cost, or daily charges, against which the odometer reading is posted every day. Under maintenance charges are recorded the expenses incurred in the upkeep of the individual car, such as tire and battery repairs and replacements, giving the number of the repair job, or of the tire and battery installed.

Itemized and Totaled Costs

The average share of garage repairs and other general labor charges borne by every truck in the garage appear under the heading Other Charges; while standard information relating to the car is recorded at the head of the sheet. Space for a short description of repair work done on the car is provided in the left portion of the sheet.

General information abstracted from these detailed accounts is recorded on the reverse side of the form, the items being arranged from top to bottom as they are from the left to the right on the face side. The difference between the figures on the two sides is, of course, that the reverse side gives the totals

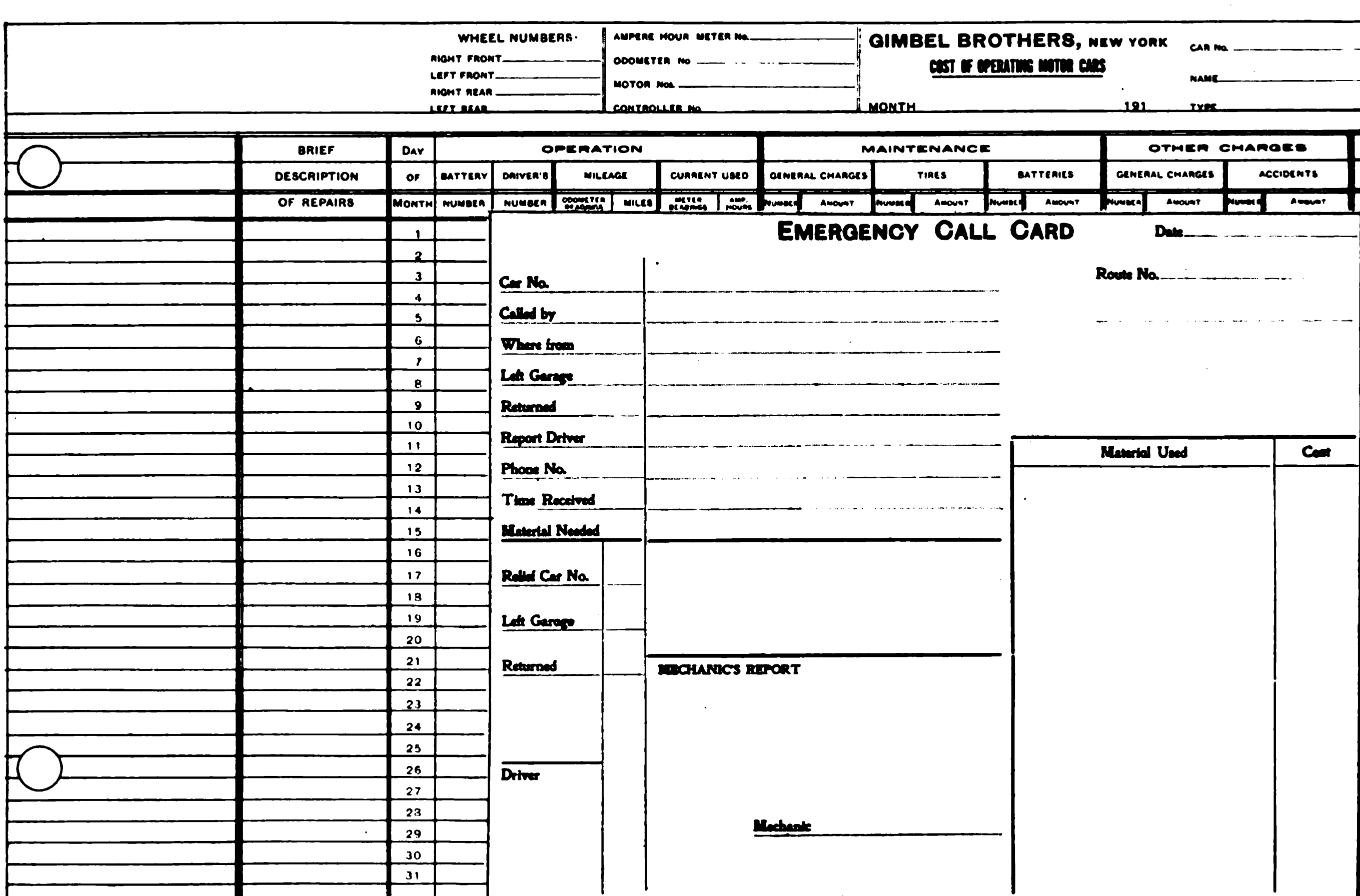

Fig. 5—Monthly record sheet for keeping track of expenses of individual trucks day by day. Fig. 6—Emergency card used at the garage for recording the cases of drivers meeting with trouble or accident while on the road

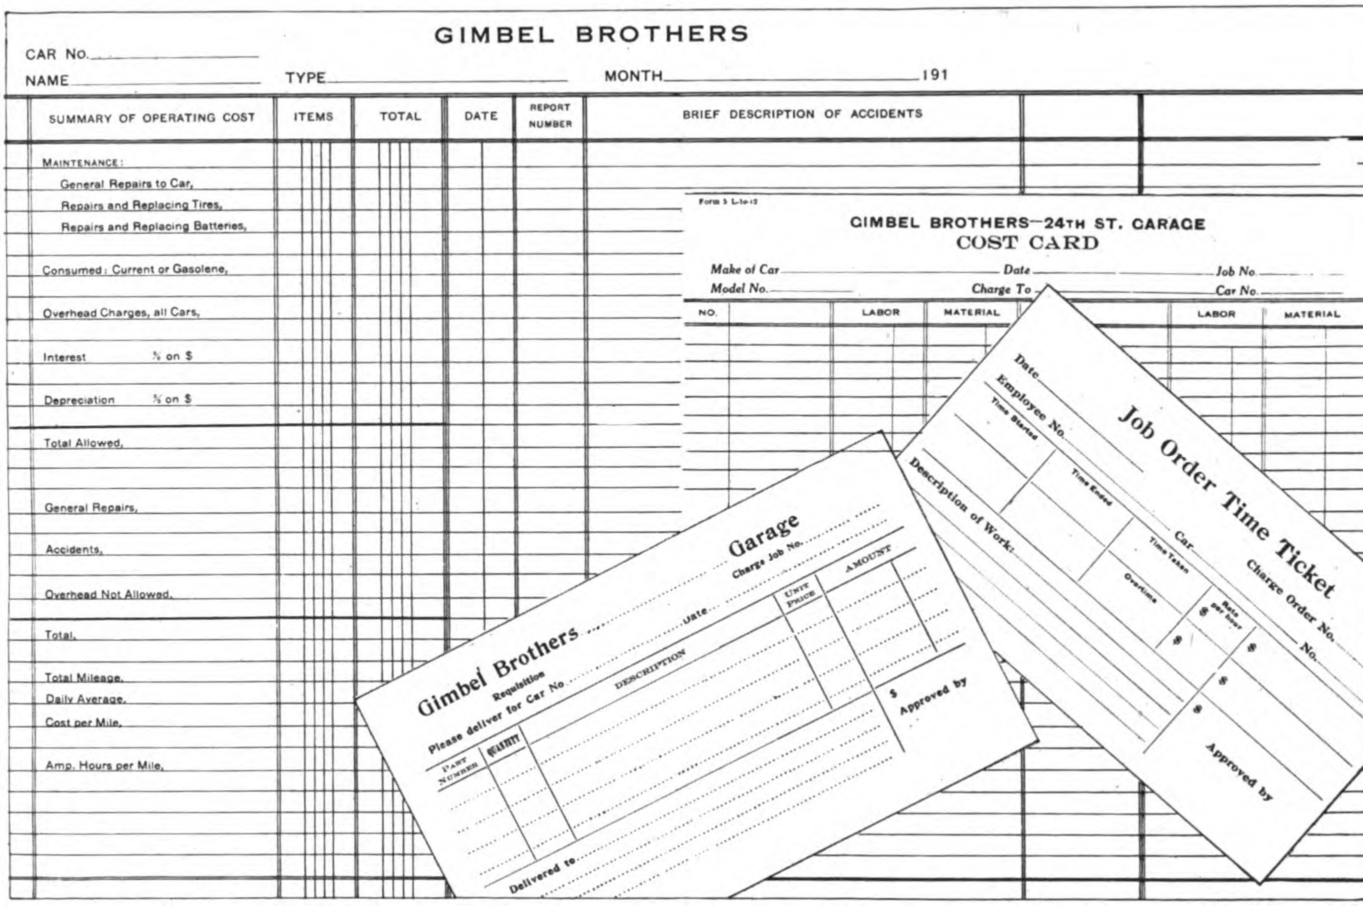

Fig. 7—Reverse of Fig. 5, being a monthly summary of truck cost. Fig. 8—Cost card for recording the labor and material expended on truck repairs. Fig. 9—Requisition. Fig. 10—Job time ticket for shop work

for the months, referring to the several items, which are obtained by footing the respective columns on the face side. Fig. 7 shows that the total of maintenance charges also includes the interest on money invested in the truck, the depreciation of its value specified in the guarantee and the salary of the garage superintendent appearing under Overhead Charges, All Cars.

Allowance Made for Each Truck

The total of the first group of items makes up the expenditures allowed by the company normally for every truck. To this garage repairs and overhead expenses, including the wages of the various employees, are added, making up, with the cost of accidents and insurance, as well as light, heat and power, the total expense charged to the car. The total mileage traveled by the truck during the month, the daily average mileage, also the total operating cost per mile and the ampere-hours per mile are recorded on this sheet.

The grouping of expenses in Fig. 6 under two classifications, maintenance and operation, corresponds to the financial scheme introduced by the Gimbel company for its delivery department. Gimbel Brothers allow this department a fixed expenditure including the items named under maintenance, driving energy, average part in the salary of superintendent, lost interest in the investment and depreciation of the truck. The classification of these expenditures as allowed is due to the fact that they may be closely calculated beforehand. On the other hand, operating expenses which include garage repairs and expenses, light, heat, power, accidents and garage wages may not be calculated closely in advance; these figures, therefore, call for even greater attention of the auditor and efficiency managers than the items of the first group, and it is they that are subject to continued attempts toward a reduction.

Besides the extent to which the drivers, foremen, mechanics and shop men are involved in the handling of the cost-keeping blank, and which is incidental to their principal work, two persons are required to handle this system in the office, to segregate the time and cost records and to put them in a shape in which they may be easily referred to. The men in charge of the delivery system are positive that the latter, although it seems elaborate to outsiders who understand nothing of the handling of such a big organization, pays very well; or, rather, as the delivery trucks and the garage are necessary parts of the department store business, the best thing possible is to conduct these parts of the organization as economically as possible. That this is being accomplished in the case of Gimbel Brothers' system is beyond doubt. Of course, there is more than one detail of great importance in the successful handling of such a system. One of the principal points is that the stockroom clerk or man is absolutely exact and reliable and does not permit of any material leaving his department unless on a requisition. Likewise, waste time must be guarded against in every field of the work to make success complete.

Drivers Co-operate with Company

To court all-around alertness of their employees and increased activity in all departments, Gimbel Brothers encourage their workers in every respect. They induce them to do their best, by making it clear to them that by doing so they help both the firm and themselves. One of the aims evidenced in the company's inside policies is to keep its employees content, remembering that the personal welfare is a considerable factor in the work done by any individual. At the same time no attempt is spared to educate every man or woman working for the company so as to impregnate him or her with a certain becoming dignity which is bound to make a good impression on the patrons of the store. This is proof of the fact that men in whose hands the enforcement of high operating efficiency lies, view the matter in an entirely practical light and consider system merely as a means to an end, and not as an end in itself, as is the case with less broadminded managers.

Cure for Slipping Cone Clutch; Kerosene Not a Good Non-Freezing Solution; Five Cylinders Defended—National Company Makes Own Rear Axle—Some Remarks on Carbon Trouble—Volumetric Efficiency Explained

Leather Clutch Slips on Hill

EDITOR THE AUTOMOBILE:—My car, which used to be very good on hills, now fails me in this respect. There is a hill which I used to pride myself that I could take at 20 miles an hour on high. Now if I attempt to climb it on high the motor speeds up while the car slows down and I am forced to change gears. A friend of mine has told me that this is due to my clutch, but I doubt this as it has never given me trouble and I have had the car three years. In order that you may explain the difficulty to me, however, should it be the clutch, I will state that it is a leather-faced cone with flat springs placed beneath the leather to give a gradual engagement when throwing on the power.

Pittsburgh, Pa. N. T. FUCHS.

—A leather-faced cone clutch will slip when it becomes covered with oil or glazed. The trouble is due to one of these two causes. Should it be due to the oil the remedy is to have some one pull down the clutch pedal, or you may block it down with a piece of wood, while you pour a pint or so of gasoline over the surface of the leather. This will cut away the oil and leave you clutch. An alternative of gasoline is fuller's earth, which is sprinkled over the surface of the leather, absorbing the oil. The gasoline leaves the surface of the leather cleaner than does the fuller's earth, and hence it is better. Should the clutch be dry and glazed, the surface may be again softened by the application of a thick coating of castor or neats foot oil. Another frequent cause of the slipping of a leather cone clutch is the fact that the leather is worn down and exposes the head of one of the copper rivets. This gives a metal-to-metal contact of the clutch seating and hence causes a slip. The remedy for this is to either rivet below the surface of the leather or to replace the leather itself should it be worn too far.

Kerosene a Bad Cooling Agent

Editor THE AUTOMOBILE:—We would like to know if there is any reason why kerosene oil cannot be used with better results than other agents for cooling a gasoline motor in an automobile. Do you know of any objections to its use for this purpose?

Pierson, Iowa. G. P. MCGRAW.

—The use of kerosene in the radiator as a combination non-freezing and cooling agent is an annual suggestion. It is the opinion of many who have studied the matter that while it might be a success in the very far north, it is a failure in our latitudes. In the state of Iowa there are occasional warm days even in the winter. During these periods a motor would tend to overheat readily because the kerosene would evaporate quickly and because the specific heat of the kerosene would not permit it to carry away the necessary heat of the combustion chamber per cubic foot of fluid circulated. Kerosene also rots the hose connection. It cannot be mixed with water and possesses an unpleasant odor at high temperature. For these reasons it is unsatisfactory.

Still Prefers Five Cylinders

Editor THE AUTOMOBILE:—In your issue of Nov. 28 Mr. G. C. Richards calls attention to two objections to the use of five-cylinder motors, the first being that the five could not possibly produce as steady a torque as the six, and the second that the manufacturing cost of a five-cylinder crankshaft would be greater than that of a six. Granting that both these objections are well founded, it is still the writer's opinion that they are of secondary importance and that no good and sufficient reason has yet been put forth why five cylinders would not constitute a successful motor, which would be far superior to the four, even if it did not equal the six in the continuous torque which could be obtained.

Mr. Richards himself says that he found a five-cylinder "much superior to a four." He points out that a five would not operate without a flywheel. Granted. But do not all gas engines use comparatively heavy flywheels, irrespective of the number of cylinders?

I fail to see why the five would not give practically if not theoretically a continuous torque, since the explosions would overlap each other to the extent of 72 degrees on each revolution of the crankshaft, while in the four they do not overlap at all.

As to the greater expense of a crankshaft with five offsets instead of three, I submit that dispensing with the sixth cylinder, with all its accessories, would more than make good the cost of the five shaft over that of the six shaft.

To sum up the advantages of the five-cylinder motor as compared with the six:

1. The five would be less complicated.
2. It would weigh less.
3. It would require a shorter hood.
4. It would consume less gas and oil.
5. It would cost less to manufacture.
6. It would operate with less vibration and a steadier pull or torque than any four-cylinder motor that can be built, and I am confident that it would lose little if any advantage in these features when compared with a six.

Has THE AUTOMOBILE any information regarding acetic acid as a carbon remover or spark plug cleaner?

East Canaan, Conn. D. C. CANFIELD.

—Acetic acid is a solvent of organic substances and will aid in breaking up carbon deposits as will acetone, another product of dry distilled wood. A few drops of gasoline, however, will thoroughly clean a spark plug.

Distribution Affects Traction

Editor THE AUTOMOBILE:—I have noted your comment on the subject of traction. I think you do not fully grasp the facts. The friction coefficient's importance practically disappears when the load is all on the driving wheels. Friction is needed when there is a load to push. But a load can be carried with practically no friction. Put on roller skates and try to push a load in front of you. You cannot do it unless you get friction by placing the skates more or less crosswise. But throw that load on your shoulders and you skate away with it just as freely as if you did not carry it. The folly of present automobile construction is that the motor and heavy mechanism is generally at the front where it is hard to propel and where it causes slipping of the rear tires with consequent skidding and faulty steering.

Surely you can see that a four-wheel drive does not have much bother with skidding or lack of traction. Then why should a two-wheel drive if its drive wheels carry all the weight? And it can carry so nearly all of it as to remove most of the troubles.

The cars of the future (whether far or near I do not know) will carry its main load on the drivers. I doubt if it will be a four-wheel drive because this adds needless complication. But it may and likely will be a three-wheeler because this drives two-thirds of the wheels which may carry most of the weight and need very little friction to push the lightly loaded front wheel. Why people will continue to skid into trees and telegraph poles and kill themselves I do not know. Certain it is that they can buy cars practically free from skidding.

Saginaw, Mich. CHAS. E. DURYEA.

National Makes Own Rear Axle

Editor THE AUTOMOBILE—Will you please tell me who makes the rear axle housing brake drums and hubs for the National Motor Vehicle Manufacturing Company, of Indianapolis, Ind.? I would also like to know if the same people make the differential. I am not quite sure what year car I am trying to get the information for, but it is likely that this same make of housing has been used for the past 4 or 5 years on all cars made by this company in that same length of time.

Marlboro, Mass. H. E. M.

—According to the Poertner Motor Car Company, of New York City, which handles the National car in the East, the National company has always made their own rear axle while the gears are made according to National design by the Brown-Lipe Company.

Care of Fixed-Spark Magneto

Editor THE AUTOMOBILE:—Kindly advise me the best way to find defects in operation of a Bosch high-tension fixed-spark magneto. How to get to the bushing and points. If possible, show me some pictures of them. The care and how to adjust them.

Shreveport, La. OLD READER.

—Contrary to general rule, the best care the average owner can give a magneto outside of a drop of oil occasionally, is to let it alone. Fig. 3 shows the exterior of the Bosch fixed-spark magneto. The breaker box cover A can be removed by taking out the screws which hold it in place. This exposes to view the breaker mechanism, which is shown from detail in Fig. 1. The two platinum points may be dressed off with a very fine flat file should they be pitted. The points are then readjusted by turning up a long screw holding the lower platinum point. This adjustment should not be made unless absolutely necessary. The only other attention you can give your magneto is to put a drop of very fine watch oil into the two oil holes shown in Fig. 1 every month. In the illustrations used here, Figs. 1 and 3 of the variable sparks magneto should illustrate the point, since the construction is practically the same.

Carbon the Root of Trouble

Editor THE AUTOMOBILE:—Can you suggest a remedy for my car? I have a 1907 type XV Pope-Toledo and believe it has run over 20,000 miles. Cylinders and rings are in splendid shape. In fact, the whole machine shows excellent material throughout, but it doesn't seem to develop power as it should and will knock and pound and fire back when the spark is thrown off. A month after being overhauled, and after having the carbon cleaned off, it will have absolutely no compression. On those occasions it is very difficult to start the motor, especially after being hot. I have tried different kinds of oil and don't seem to be able to get away from carbon formation, which I think is the root of my troubles. I keep my valves in pretty good shape, although the exhaust valves pit easily. My compression is pretty high, although I believe there are several cars at the present day with just as much. Perhaps you are familiar with the construction of the Pope cars at that time and can help me out.

Do you think it would be advisable to reduce its compression?

Rocky River, O. A. MORTON.

—The fact that you are continually bothered with carbon trouble and that the compression in your motor is high shows the backfiring, etc., is due to nothing more than an accumulation of carbon. The carbon will become deposited in a conical heap upon the head of the piston or other points in the combustion space, and the result is that the apexes of these small cones become incandescent under the influence of the heat to which they are exposed. The gases in the cylinder, being under a high compression, are very easily ignited, hence the backfiring through the intake manifold is due to the fact that the mixture is sometimes ignited as it is rendering the cylinders, causing the fire to penetrate into the intake manifold.

The proper cure is not the frequent removal of the carbon, but the removal of the cause of carbon deposit. The principal causes of this are: 1—too much oil; 2—poor ignition; 3—bad-fitting piston rings; 4—failure to drain out old oil in crankcase. These may be taken up individually and the proper steps for removing these causes pointed out.

1. This is due, in splash-lubricated cars, to the fact that there is too much oil in the crankcase and hence the connecting-rods dip too deeply and throw too much oil up into the cylinders. The cures are: 1—the shortening of the scoops on the connecting-rods; 2—filing the sides of the troughs which contain the oil so that they will overflow earlier; 3—the installation of a baffle plate in the lower part of the cylinder, which will prevent the oil from working its way up into the combustion chamber. This baffle plate takes the form of a common angle piece bent in a circle around the lower end of the cylinder. The vertical flange is fastened to the cylinder wall below the bottom of the piston stroke by means of small screws, while the horizontal flange forms the baffle. It is necessary, of course, to cut two slots in the baffle plate to permit the connecting-rod to work without striking same. In all these cures it is necessary to be extremely cautious so as not to cut down too far the supply of oil to any cylinder, as the results of this would be far more serious than an over-supply of oil. In other words, the changes made in the length of the scoops or the depths of the troughs should be

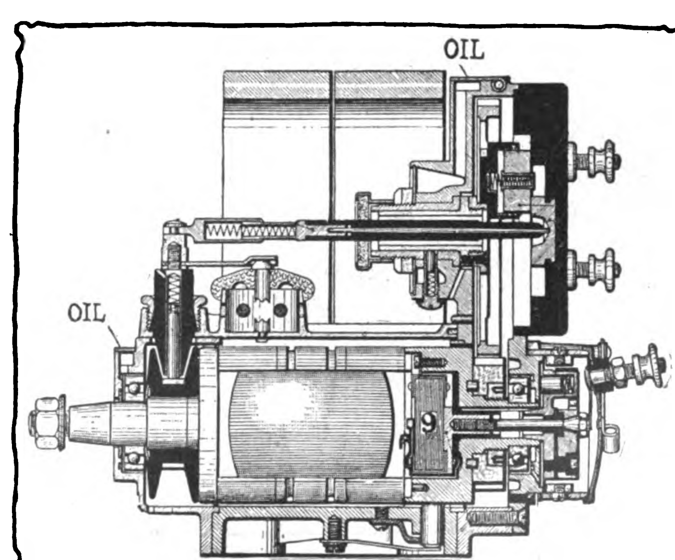

Fig. 1.—Section through Bosch magneto with two oiling points indicated

very minute at first and enlarged only after experiment. The baffle plate should be small at first, and made larger only if it is seen that the supply of oil which reaches the cylinder could be still further curtailed.

2. Poor ignition may cause carbon trouble indirectly. Whenever a misfire occurs a certain amount of oil which would otherwise be consumed by the heat of combustion is permitted to remain in the combustion space. Should the misfire endure for five or six explosion strokes of this particular cylinder and then be followed by an explosion on the succeeding stroke, the large quantity of oil which would be deposited in the combustion space during the strokes upon which the misfire occurred would be partially consumed, leaving a heavy black residue of carbon which would be deposited on the cylinder walls, the piston head and other spots, where it would be likely to cause the premature ignition as explained above.

3. Ill-fitting piston rings cause carbon deposits because they allow the oil to get by the piston and up into the compression space. The accumulation of too much oil in the combustion space causes trouble in the matter pointed out under 2. The cure for this is to replace the worn rings in the same manner that the cure for 2 would be in going over the ignition, locating the seat of trouble and removing it.

4. In the circulating splash system the common mistake made by many automobilists is the failure to drain out the old oil in the crankcase. This is no doubt due to the fact that it is rather unpleasant work, necessitating crawling under the car and removing drain plugs or opening up drain pipes that are rendered inaccessible because of the presence of the mudpan. Removing the mudpan itself and replacing it is no little work in itself. Oil which is circulated through the lubricating system of internal combustion motor becomes charred and waxy, rendering it after a time unfit for cylinder lubrication. For this reason it should be made a rule that the old oil be drained out thoroughly and the crankcase flushed with kerosene oil every 1,000 miles before the new supply of oil is put into the crankcase.

Meaning of Volumetric Efficiency

Editor The Automobile:—What is the meaning of volumetric efficiency, and has it any relation to mechanical efficiency in an internal combustion engine?

Bronxdale, N. Y. Gustave Mittenzwei.

—In a gasoline motor the piston never draws in as much gas as is represented by the volume of its displacement. The amount of air or gas actually drawn in in one stroke divided by the actual displacement of the piston is equal to the volumetric efficiency. The volumetric efficiency decreases as the motor speeds up, and also varies directly with the size of the inlet valve. It is affected also by the valve timing and the temperature of the cylinder walls. The Society of Automobile Engineers in the transactions for January, 1911, reports a paper presented by Professor R. C. Carpenter showing that a Franklin 4 by 4-inch air-cooled motor fitted with 1.375-inch diameter poppet valves, opening 5 degrees past upper dead center and closing 30 degrees past lower dead center, had, when driven by an electric motor at 1,000 revolutions per minute, a volumetric efficiency of 82 per cent. At 1,500 revolutions per minute the volumetric efficiency dropped to 68 per cent. When run under its own power with the same valve timing the volumetric efficiency at 1,000 revolutions was 68 per cent. with applied phosphor bronze cooling fins, and 62 per cent. with cast-iron integral ribs. At 1,500 revolutions per minute the percentages were 63 and 56 for the phosphor bronze and cast-iron ribs, respectively. This shows the effect of the cylinder-wall temperature on the volumetric efficiency, as the engine was old when run by the electric motor, and was cooled to different degrees by the phosphor bronze and cast-iron ribs.

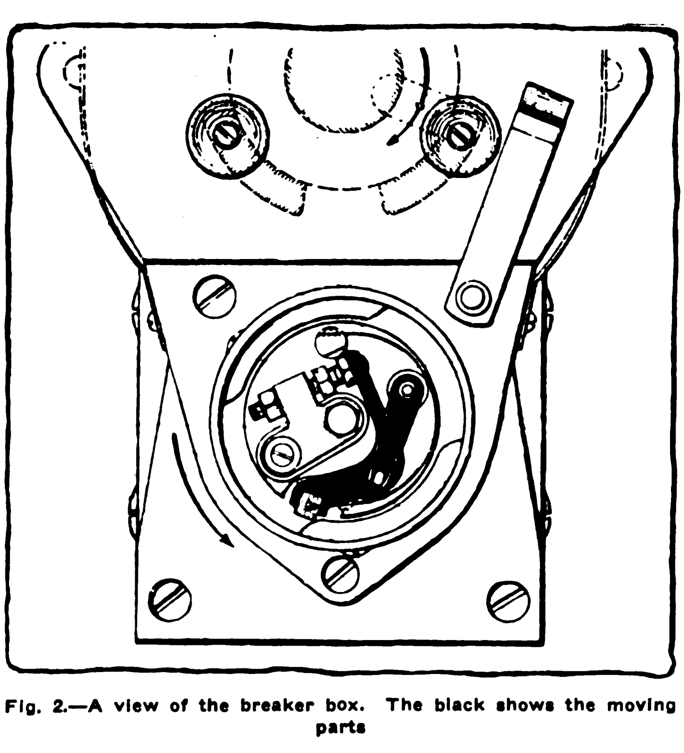

Fig. 2.—A view of the breaker box. The black shows the moving parts

Correct Temperature of Vulcanizing

Editor The Automobile:—Would you please tell me to what temperature rubber should be raised when vulcanized? Is there a wide range of temperature or should it be held within 1 or 2 degrees of a given heat?

Holyoke, Mass. B. Z. Cruger.

—The correct vulcanizing temperature ranges between the limits of 250 and 300 degrees Fahrenheit. There are thermometers on the market which are just graduated through the range used in vulcanizing and which are of good use in this connection. Many of the patented vulcanizers are so designed that the temperature cannot rise above what is proper for vulcanizing. This is necessary because where the temperature gets above 320 the rubber structure is broken down by what may be called a form of destructive distillation, while below the vulcanizing range the action is not thorough enough to give good results.

Underinflation Causes Tire Cracks

Editor The Automobile:—I have recently bought a second-hand car upon which the tires were stated to be in good condition. Upon close inspection of the casings I find that the walls are filled with a series of cracks. Would you please tell me if this is due to any fault in the tires or because the former owner of the car did not give them proper care?

Houston, Tex. P. P. Moore.

—The cause of cracks in tire casings is underinflation. If you will keep tires pumped to a pressure equal in pounds to 20 times the cross-section dimension in inches you will have no trouble. Assuming that your tires are 4 inches in diameter the correct pressure would be 80 pounds, or, for a 4.5-inch tire, 90 pounds, and so on through the gamut.

The Best Non-Freezing Solution

Editor The Automobile:—Would you please tell me the solutions that are commonly used in preventing the water from freezing in the radiator.

Detroit, Mich. Carl Schneider.

—In the issue of October 24, the question of non-freezing solutions was fully taken up and the merits of all the solutions was explained. A digest of the remarks in that issue follows:

—There are three well-known anti-freezing compounds which have been used extensively and which have proved themselves to be valuable for this work. They are alcohol, glycerine and calcium chloride. Besides these there are many others that are good, but they nearly all have some drawbacks that prevent them from being as useful as would otherwise be the case.

About the most popular of all the solutions to use in the motor is the alcohol. Wood alcohol or denatured may be used. The cost is small; denatured alcohol may be purchased for 60 cents per gallon and the price of wood alcohol is about the same. The advantages of alcohol are that it is very easily handled and that there is no action on the metallic parts of the circulating system.

Taking wood alcohol alone the following solutions may be used:

Freezing Point	Wood Alcohol	Water
+ 5 degrees Fahrenheit	20 per cent.	80 per cent.
0 " "	25 " "	75 " "
— 5 " "	27 " "	73 " "
—10 " "	31 " "	69 " "
—15 " "	35 " "	65 " "
—20 " "	38 " "	62 " "

When using denatured alcohol the freezing point will be different. In tabular form for temperatures between 5 above and 20 below zero Fahrenheit, the denatured alcohol solutions will be as follows:

Freezing Point	Denatured Alcohol	Water
+ 5 degrees Fahrenheit	24 per cent.	76 per cent.
0 " "	29 " "	71 " "
— 5 " "	32 " "	68 " "
—10 " "	34 " "	66 " "
—15 " "	37 " "	63 " "
—20 " "	40 " "	60 " "

Glycerine possesses many characteristics which would seem to stamp it as the ideal non-freezing agent. The boiling point is high and, as many experiments have proved, does not change the boiling point of the mixture regardless of the percentage added to the cooling water. Glycerine reduces the freezing temperature materially when added to the water, but does not do so as rapidly as wood or denatured alcohol.

When reducing the freezing temperature to such an extent that the water will not freeze in a cold climate it is necessary to add so much that the water tends to become gelatinous and for this reason it has been mixed very often with wood or denatured alcohol in a very successful attempt to combine the merits of the two. When glycerine alone is used the mixtures that are required for different temperatures will be found in the following table:

Freezing Point	Glycerine	Water
+28 degrees Fahrenheit	10 per cent.	90 per cent.
+15 " "	30 " "	70 " "
+ 5 " "	40 " "	60 " "
0 " "	48 " "	52 " "
— 5 " "	54 " "	46 " "
—10 " "	58 " "	42 " "

When the glycerine and alcohol are used together they are used in equal quantities. This mixture, which is purely mechanical, has not as great a tendency to rot the hose connections as a pure glycerine solution would have. It has more water in it than would the latter and is thus more free to pass through the radiator and other parts of the circulating system without doing harm. On the other hand, there will be less alcohol in this solution than there was in the pure alcohol solution and the result of this is that there will not be so much evaporation and necessary replacement of the cooling fluid after the motor has been run for a time. The glycerine and the alcohol are stirred up together and added to the water in the following proportions:

Freezing Point	Mixture	Water
+20 degrees Fahrenheit	15 per cent.	85 per cent.
+15 " "	20 " "	80 " "
+10 " "	24 " "	76 " "
+ 5 " "	27 " "	73 " "
0 " "	29 " "	71 " "
— 5 " "	30 " "	70 " "
—15 " "	32 " "	68 " "

We now come to calcium chloride, $CaCl_2$, and water. This compound has been recommended by many and is very good, although it has its dangers in the difficulty of securing the chemically pure article. In buying the calcium chloride for use in the cooling system of an automobile the crude article costing about 10 cents a pound should not be purchased. The chemically pure article costs about 25 cents a pound and is very satisfactory. The objections to the use of the material is its tendency to set up an acidic action in the radiator. Chloride of lime, which should be kept out of the radiator, is often a constituent of the commercial calcium chloride and care must be used in getting the chemical from a reliable concern which will guarantee the purity of its products. With the calcium chloride solution the percentages are given by weight instead of volumes as are the other tables:

Freezing Point	Calcium Chloride by Weight	Water by Weight
+10 degrees Fahrenheit	15 per cent.	85 per cent.
+ 5 " "	17 " "	83 " "
0 " "	19 " "	81 " "
— 5 " "	21 " "	79 " "
—10 " "	22 " "	78 " "
—15 " "	23 " "	77 " "
—20 " "	25 " "	75 " "

The above is reproduced from THE AUTOMOBILE of November 21 in order that it may reach many automobilists who at this time of the year are very apt to be careless. The weather is down below the freezing point in nearly all the Eastern States at this time of the year and to leave the radiator without some non-freezing solution is to court disaster. All the mixtures mentioned in this list are practical and have been given the stamp of approval by a large number of motorists.

Caught With Short Fuel Supply

Editor THE AUTOMOBILE:—I wish to relate my experience of last summer, when an excessive grade found me short of gasoline and remote from supply. A party of us were making the Sonora Pass, leading over the summit of the Sierras at an elevation above 9,000 feet. We came to a short, steep grade which shut off the gas. It was near lunch time and 40 miles from a garage. We lunched and talked over the predicament. I finally suggested that we detach the feed pipe from the tank and place it in a perpendicular position from the carbureter. This was tried, and, much to our satisfaction, it would hold enough juice to place us safely over the grade. This may help some other man in a like predicament.

Gardnersville, Nev. W. M. MAULE.

—It is good to turn around and back up in a case of this kind. Another expedient which is sometimes resorted to under these circumstances when the road is too narrow to permit of turning around to back up the incline consists of closing the gasoline pipe at the bottom of the carbureter and then filling the float chamber of the carbureter. One filling will generally enable the car to reach the summit of the hill.

Four-Cylinder Model Added to Fiat Line

Three Models Now Turned Out at the Poughkeepsie, N. Y., and Turin, Italy, Factories Are Identical

Italian Engineering Staff at American Factory Insures Uniformity—Stampings Imported from Parent Factory

FOR next season the Fiat company from its American factory at Poughkeepsie, N. Y., and its foreign factory, Turin, Italy, will market three chassis types, two fours and a six, namely: Model 54, four-cylinder, 110 by 150 millimeters or 4 2-5 by 6 inches bore and stroke; Model 55, four-cylinder, 130 by 170 millimeters or 5 1-8 by 6 3-4 inches; and Model 56, six-cylinder, the same bore and stroke as Model 54. These three models represent different years of Fiat development, in that the small four Model 54 was brought out 2 years ago, Model 56, the six, last year, and the new model 55 for next season. All three chassis are alike in general details, showing that the principles of construction in the Fiat factory were well outlined and settled several years ago.

The American factory turned out its first car in October, 1910, and since that time has been producing Fiat models of the same design as those made in Italy. The parent company furnishes the engineering staff, working drawings, and some of the materials and parts. The processes of construction are identical in Poughkeepsie with those in Turin, an Italian engineer living at the American factory to be certain that every detail of the foreign factory is incorporated in the American product. Several of the parts of the American car are imported from Italy, an example being the steel stampings constituting the housing for the rear axle and torque tube, which come direct from the patent factory. The materials entering into the other parts of the cars are of the same analysis as those prescribed by the Fiat engineers in Italy.

The Fiat motor, a block casting, in the four and six-cylinder models is shown in Figs. 1 and 2, these being reproductions of the new Model 55. The design is simplicity throughout, having as cardinal merits the block casting, inclosed valves, and the transverse forward shaft driving the pump and magneto. The carbureter is located on the non-valve side and connects with the casting through a brief elbow, the remainder of the intake manifold being within the water-jacketed casting, thereby guarding against mixture condensation.

The aluminum two-piece crankcase is a product of the factory foundry at Poughkeepsie, as are the gearbox and other aluminum castings.

Fig. 5, end and side sections of the motor, shows the compactness, due to the use of a block casting. This casting for the six-cylinder car has an overall length of 37 inches, is 13.75 inches high, and 11 inches wide. In the Model 55, the large four illustrated, the casting has an overall length of 28.5 inches. Bo : elevations show how the engineers have aimed at avoiding parallelism in the interior water-jacket walls, and also show the efforts at W to adequately water-jacket that part of the casting adjacent to the valve stems. At W1 is shown the intake manifold crossing between the second and third cylinders and also showing its water-jacketing.

Silencing the Valve Action

Every care has been used to obtain quietness in valve actuation, and also the maintenance of this. In Fig. 4 is shown the valve system. Each valve is a three-part one made up of an 18-20-point carbon steel stem, a 30-35 per cent. nickel steel head, and the beveled portion a cast iron ring. This has been done to give the necessary strength in the valve head, and also that freedom from pitting on the beveled seat which is obtained by cast iron. The seats are beveled to 30 degrees instead of 45, this being done to give a quicker and wider opening. Valve tappets are hardened and ground and small allowances used between the tappet T and its guide G, the permissible allowance being .004 millimeters minimium and .006 millimeters maximum over or under size. The camshaft has cams mounted by keying and pinning on the shaft, the cams being in pairs, intake and exhaust for each cylinder. By using detachable cams it is possible to use non-split bushings for the shaft.

On Model 55 a compression release is used, this taking the form of raised cams integral with the regular cams. To use these it is necessary to slide the camshaft endwise, and to make this possible without moving the timing gear, the shaft carries a two-arm yoke driver Y on its forward end, and this driver connects with the timing gear through a pair of hardened and ground pins S which the gear carries. These pins are of greater length than the driver thickness so that when the camshaft is moved forward, the yoke slides on them. The driver has hardened and ground bushings. The movement of the shaft is effected by a collar C into which works a conventional yoke operated through a pull lever extending to beneath the radiator.

In mounting the transverse shaft driving the magneto and pump spiral gears have been used. The shaft, Fig. 3, is carried on two races of ball bearings with a thrust. It has its driver G formed integrally, and meshes with a bronze gear. The teeth are cut at 45 degree angle. The shaft couples with the magneto and pump by flexible coupling K. The drive is entirely inclosed, and is well lubricated. This illustration shows a compact coupling in connection with the magneto drive, which is carried from front to rear through the motor crankcase. From the breaker box a vertical link L enters the crankcase arm and transmits through a cross-lever L1 to the horizontal shaft S extending to the rear of the crankcase, where there is a short coupling to the control parts on the steering column.

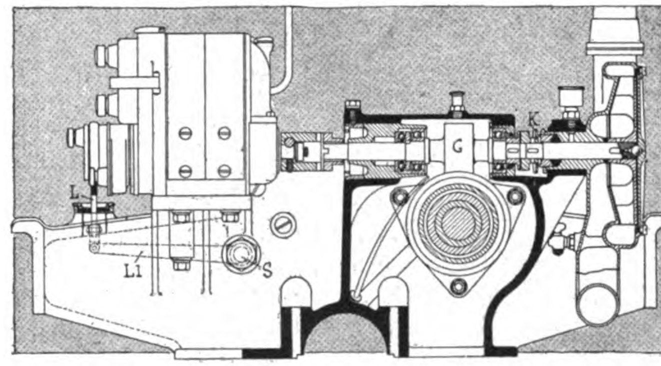

Fig. 3—Ball bearing magneto and pump drive used in Fiat cars

Chrome Nickel in Crankshaft

Every care is used in the manufacture of the moving parts. The crankshaft in all models is of chrome nickel alloy carried on three bearings in the four-cylinder models and four in the six. It is hollow to facilitate force-feed lubrication, not only to the lower connecting-rod bearings, but also to the wrist pins. The crankcase is heavily webbed internally and to insure adequate rigidity reinforcing plates are used to support the bearing caps, these plates being carbon steel forgings held by four alloy steel studs.

Lubrication is force-feed and non-splash. A small gear oil pump mounted on the rear end of the camshaft raises the oil from the reservoir and delivers it to a horizontal copper pipe inserted during the casting process in the crankcase, of which it extends from end to end. Branches lead from this duct to the three main bearings. From these bearings the oil flows through a drilled crankshaft to the crankpins and thence through copper pipes attached to the connecting-rods to the wrist pins. To prevent an excess of oil being misted into the cylinder from the throw of the crankpin, integral baffle plates are formed in the top of the crankcase. The crankcase has a capacity of 4 to 5 gallons.

An interesting detail is the mounting of the oil pump on the rear end of the camshaft. Its position is shown in Fig. 6, as

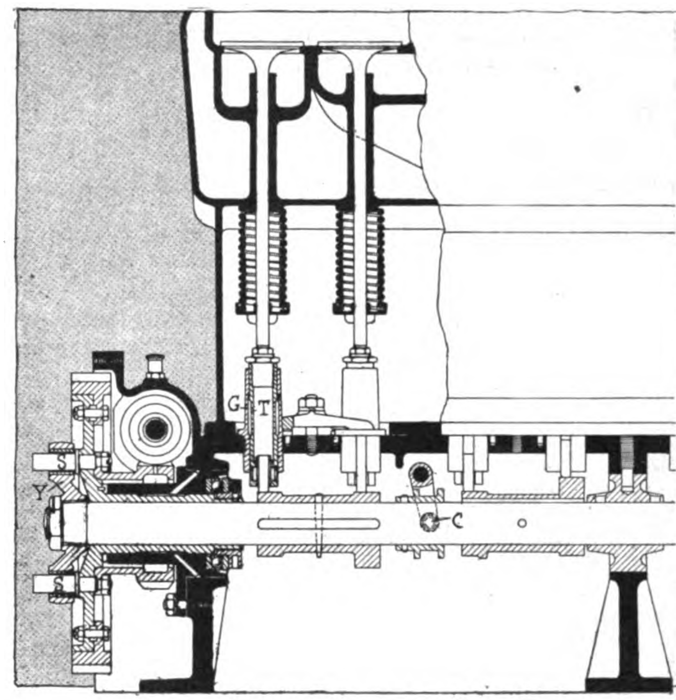

Fig. 4—Camshaft and valve lifter mechanism in partial section

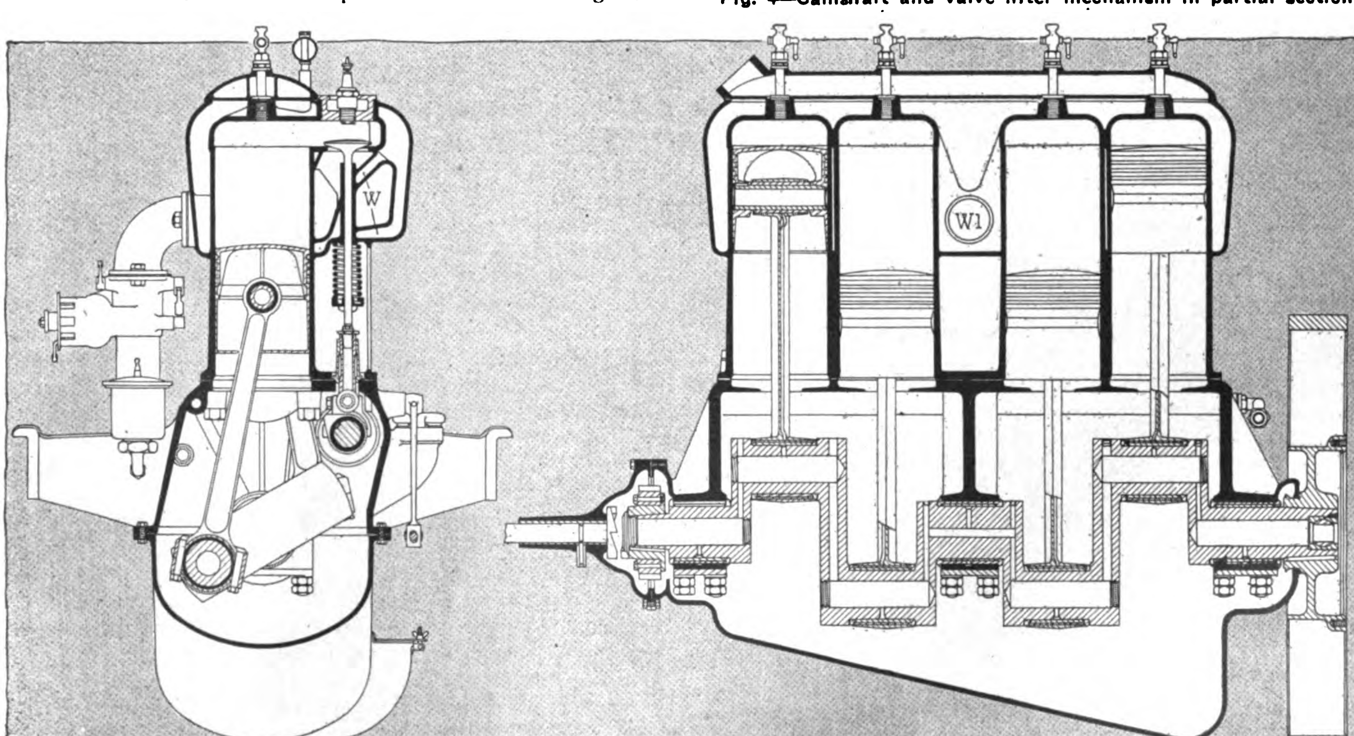

Fig. 5—Transverse and longitudinal cross-sectional views through the four-cylinder Fiat motor, illustrating oiling system

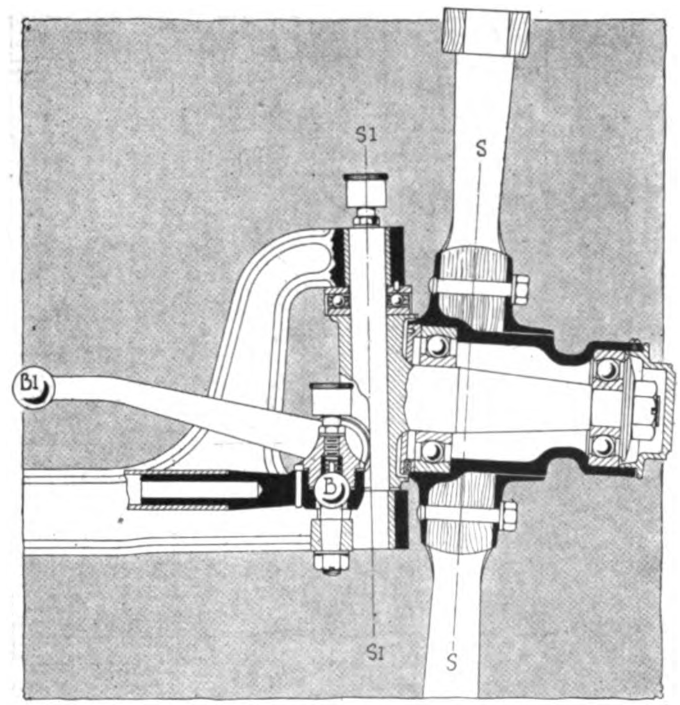

Fig. 6—Ball bearing steering knuckle and spindle. Note wheel slope which is measured by the converging lines through the center of the steering knuckle and of the road wheel designed to give minimum tire wear and easy steering

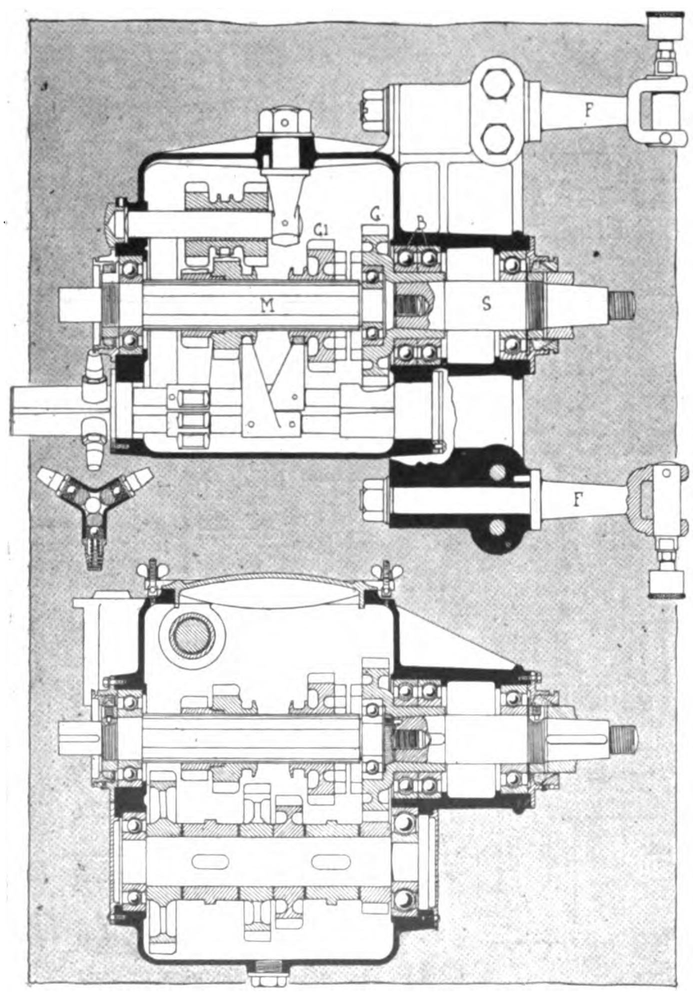

Fig. 7—Sectional plan and elevation of the Fiat gearset, showing the arrangement of the shifter dogs and the mounting of the shafts on single and double ball bearings. The mainshaft extends practically throughout the length of the case

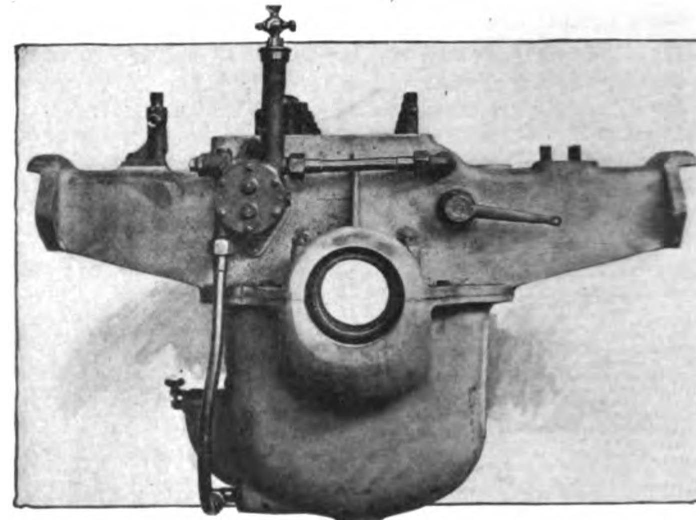

Fig. 8—End view of crankcase, showing the external oil leads

well as the vertical pipe through which it lifts the lubricant from the reservoir and the short horizontal pipe through which the oil flows to enter the copper tube extending from end to end of the crankcase. In Fig. 3 the master gear G of the oil pump is shown attaching direct to the end of the camshaft K, through a hole drilled in the end of the shaft. Into this hole the nut is threaded, this nut having a square center to receive the shaft of the gear. The oil pump housing bolts direct to the end of the crankcase. By this unique coupling the necessity of additional gears or shafting to drive the oil pump is eliminated.

For convenience the Fiat transmission system may be considered in three units, the multiple-disk clutch, the four-speed gearset and the combined rear axle and torque tube. The multiple-disk clutch, Fig. 10, consists of sixty-five steel disks in sets of thirty-two and thirty-three. The carrier C mounted on the forward end of the shaft connecting with the gearbox is insured of alignment in that the forward end of the shaft extends into the recess in the crankshaft and is supported through a spherical bushing B in turn mounted in another bushing B1 threaded into the end of the crankshaft. This gives a ball-and-socket support. The prevention of oil leaking from the clutch housing is dependent upon a packing P. The company furnishes two other types of packing for this position, both illustrated and designated P1 and P2.

Compact Four Speed Gear Used

The four-speed gearbox Fig. 7 is especially compact, measuring 10 inches from the center of the front bearing to that of the rear. The gearset is a reverse design over that in common use, in that the mainshaft M, which connects with the clutch, extends practically throughout the length of the case, and the stubshaft S protrudes through the rear and couples by universal joint with the propeller shaft. Shafts and gears are of alloy steel and supported on seven ball bearings, there being three braces supporting the stubshaft, a double race B immediately in rear of the integral gear G on this shaft, and a single race 3 inches further to the rear and mounted in a continuation or neck of the gearbox. The mainshaft has four integral splines and carries two sliding units.

The gearbox is a two-part aluminum casting, with the mainshaft mounted in the top portion, and the bearings for the countershaft located between this and the bottom part. The top is a large coverplate. The opposing faces of halves of the gearbox are milled to prevent oil leaks. The gearbox has a heavy horizontal web at the rear in which are carried the two forgings F forming the trunnion supports for the yoke of the torque.

Adequate packings for the prevention of lubricant leaking from the gearbox are mounted at both ends of the mainshaft, these packings being held by a threaded nut. The lubrication of the gearset is looked after in every detail to the extent that the reverse gearshaft has a spiral oil groove cut in it and the reverse gear is fitted with a bronze bushing. Supporting the rear end of the mainshaft in a ball bearing within the gear G facilitates lubrication at this point.

The rear system is not illustrated or described herewith, but is the subject of a special article in a succeeding issue. This axle is a special Fiat design in which the housing for the axle and propeller shaft is made from two stampings bolted together. One stamping forms the upper half and the other the bottom half.

Ball Thrust on Steering Knuckle

In the running gear the Fiat rigid frame construction is used throughout, it having the side members very heavily flanged in the region of the dash, and tapering gradually fore and aft. The front axle is noteworthy in that the design of the steering knuckle is to reduce tire wear. Fig. 6 shows the center line S of the wheel which toes in, and line S1 marks the center line of the spindle toeing slightly out so that these two lines intersect at the point where the tire rests upon the ground. This gives the minimum tire wear, and easy steering. Easy steering is further obtained by the use of ball-and-socket joints B at both ends of the tie-rod connecting the knuckles, as well as at B1 the end of the arm which connects to the steering mechanism. The car weight is carried on a ball thrust bearing beneath the upper jaw of the knuckle, and grease-cup lubrication is fitted wherever necessary.

Without allowing these lines to intersect at the ground, the front tires are subject not only to greater wear but every road shock is transmitted to the driver's hand through the steering mechanism. The reason for this is that every time the front wheel hits an obstruction it creates a turning moment about the steering knuckle due to the small lever arm, which is equal in amount to the distance between the point where the center line produced strikes the ground and where the vertical diameter of the wheel strikes the ground. This turning moment is transferred from the road to the driver's arms through the medium of the steering mechanism.

For the first time the Fiat company has scheduled a full equipment on all models this season. This includes mohair top, windshield with rain vision, Gray & Davis generator, and dynamo for electric lights, speedometer, clock, Klaxon horn, Q-D demountable rims, trunk rack, tire irons and other body essentials.

All three models have a standard line of bodies including seven-passenger touring types in curved panel or flush-sided styles, five-passenger phaeton, convertible roadster, limousine, and laundalette. The wheelbases measure 123, 128, and 135 inches respectively, on the three models.

Sane Legislation Needed

MASSACHUSETTS, by recent action of one of its courts, has instituted a new ruling in the use of the highway by motor vehicles, and it is now imperative for an automobile to pass a street car on the left side when on the highways of the state. The feature of the decision lies in classifying the trolley car with horse-drawn and motor vehicles using the road. Heretofore it has been customary to pass trolley cars on the right side but the injury to a person alighting from a trolley car by a passing automobile has resulted in the new decision.

Today Massachusetts is in a worse predicament because of this decision than it was before. There is more danger to the public, embracing those who use the highway, by compelling motor vehicles to pass street cars on the left than there was in passing them on the right. This decision has brought the impossible into the limelight. Frequently on highways the street car does not occupy the center of the highway, being closer to the left side than to the right, in which exigency there is nothing for the motorist to do but keep back of the trolley car, stop when it stops, slow up when it slows up and do everything in general to congest traffic by the reduced pace.

It is almost impossible to conceive how long legislatures will continue to legislate against motor cars in use on the highways without any apparent regard for others who use these highways. Pedestrians and automobilists have equal privileges on the highway, yet when the person alighting from the trolley car is warned by the automobilist's horn but walks backward into the automobile, the courts apparently see only the automobilist and the legislatures begin more campaigns against motorists without the slightest effort to control the pedestrian in any way whatever.

It is true that pedestrians are directly responsible for a great many accidents in which automobiles figure. The pedestrian entirely ignores the rules of the highway, often failing to look to the right or left when starting to cross a street or highway. Such is not rational use of the highway in spite of the law that both the pedestrian and the vehicle user have equal rights thereon. It would be more beneficial if legislatures took up the question of pedestrian control chiefly within the limits of incorporated cities and towns. In our big cities millions of dollars are lost annually because of delays at crossings occasioned by the pedestrians not observing the rules of traffic at city street intersections. In New York in several sections an effort is being made to control such pedestrian traffic. A similar effort is to be instituted in Chicago. The great value of such an effort will be the habit that will be established in the minds of the pedestrians. The traffic control by policemen at street intersections has got automobilists into the habit of observing such regulations whether the policeman is on hand or not. Contrast this with the pedestrian who feels that dozens of times every day he is disregarding the police control, by crossing streets contrary to traffic rules where policemen are in control. Such a pedestrian becomes a law unto himself or herself so far as crossing streets is concerned. He or she fails to start crossing the street in the proper mental frame of mind that is necessary in these days of increased automobile traffic. The only way to correct this, in other words to secure the proper mental attitude, is by rigid regulation, regulation by the police. This and only this will result in proper regard for other street traffic by pedestrians.

Many cities have legislation today forbidding passing a stationary trolley car, one stopped to take on passengers or let others off. Such a regulation is necessary in cities with narrow streets, but the abuse of such an ordinance is working ill in several cities today. Such regulations are increasing street congestion, which in itself offers a fresh difficulty, and it is questionable if it would not be much better to call for a slow cautionary pace for automobiles passing standing trolley cars and arrest for violation, than to insist on the full stop, which invariably adds to the noise of the city and requiring higher speed to overtake the trolley and pass it.

The automobile is modern transportation, it is here to increase annually in numbers and in use. It will be on the city streets as long and perhaps longer in many places than the trolley car. The city officials should recognize this and legislate accordingly. It is just as important for pedestrians alighting from a trolley car to look back of them before beginning to walk to the sidewalk as it is for an automobilist to observe traffic rules at street intersections. The pedestrian must do his or her part. The police must do their part in educating the pedestrians, and when this is done accidents will be reduced and traffic congestion be relieved to a considerable extent.

Co-operation the Solution of Traffic Problems

James S. Marvin, Traffic Manager of the N.A.A.M., Covers Subject from Practical and Academic Standpoints in Paper Presented at Recent Convention in Detroit—Industry Pays $6,000,000 a Year Freight

THE development of our railroad systems has been rapid and has made possible our present industrial development; both are dependent on each other, and the manufacturer relies on reasonable efficiency at all times of the carriers which serve him; if the schedule between his factory and a certain market is 3 days, his business is tuned acordingly and he expects the schedule to be pretty closely maintained and that there will be cars available when he is ready to ship.

Now let us consider the situation of the automobile industry in its relations to railroads with respect to service. We have first to realize that the automobile, itself an article which is entering very largely and is destined to take an increasing part in the solution of this question of transportation, has nevertheless presented a new problem in freight transportation for the railroads. **I refer to the fact that the ordinary box car is useless for automobile service for the reason that the door openings will not admit any but the smaller machines; therefore, if the freight equipment of the railroads today was the same as 10 years ago, the development of the industry would have been impossible so far as dependence upon the railroads for transportation is concerned; aside from a few old-fashioned carriage cars and open cars, the transportation facilities for automobile factories would have been little better than if we had no railroads at all!**

This is an aspect of the situation that is not always realized; nevertheless it is fact that to keep pace with the development of this industry, railroads have departed from their old-time methods of designing door openings in freight cars to the extent of about 50,000 box cars, valued at perhaps 60,000,000, without which it would have been impossible to ship any but the smallest machines completely assembled.

It should not be understood, and I do not mean to say, that the railroads built these cars for the exclusive use of automobile shippers, or that the cars are of such a nature as to render them unfit for other freight service; **what I do desire to bring out is that the automobile industry is particularly susceptible to serious effects from freight blockades, because the factories cannot draw from the million and more box cars in general service,** but their shipments are confined to and are dependent upon these 50,000 automobile cars that are circulating around the country and are mixed in with all other kinds of freight cars.

The nature of the automobile business is such as to scatter these 50,000 cars in about as effectual a manner as could be devised; the factories are spread over a wide territory and each one ships to every section of the country. The problem of keeping these automobile cars moving back into the automobile manufacturing territory would be simplified greatly if outlying railroads gave closer observance to the rule requiring return of freight cars to the home road, as the automobile cars would come back with the others, but this rule, unfortunately, is not always enforced.

When industries in general find it difficult to secure sufficient freight cars, the situation is rendered all the more difficult for automobile factories, for when a car shortage occurs shippers of other articles gain the use, to a large extent, of automobile cars.

Such a shortage exists in this country today; the railroads are right now taxed to the limit of their resources in handling the exceptionally large crops and a heavy movement of traffic of all kinds. One of those periods exists at this time when the return of freight cars to the home roads is difficult of enforcement, and when it is considered that the observance of this rule is all that the automobile industry has to depend upon for the shipment of its goods, the real aspect of the situation confronting us is apparent.

To shippers of other articles which can be loaded in ordinary box cars it does not matter so much if the car which they load is owned by the railroad furnishing it to them, but the automobile shipper hasn't this choice, and must, in the main, depend upon the outlying railroads returning the initial lines' automobile cars. We have not, therefore, depended entirely on the railroad companies' rules. The traffic department has adopted many measures tending to co-operate with those rules and point out to railroads throughout the country the necessities of this particular industry and its dependence on the proper handling of automobile cars after they are made empty by dealers. To the tracing of the owning roads we have added our appeals to the outlying railroads that this equipment be given loads only such as will take the cars back to the manufacturing territory, instead of sending them to points entirely out of line.

In the belief that a full understanding of the situation on the part of automobile dealers throughout the West and South would be of assistance, we have outlined the situation so that the factories could explain it to their dealers and the latter to their local railroad people.

The advantage of using automobile cars for hauling supplies and material to automobile factories has been explained and encouraged, and we have called attention of our members to the necessity of keeping every automobile car actively in service by loading and unloading promptly and refraining from tying them up by loading in large quantities to dealers who cannot accept drafts and as a consequence would leave the automobiles in freight cars at destination a considerable time.

There are few more important questions confronting the business interests than these periods of car shortage which seem bound to recur under existing conditions. A general and far-reaching interruption of traffic contains possibilities not only of financial disaster, but of actual privation and suffering. There seem to be times when the methods in vogue on the part of railroads and on the part of shippers invite such results. The facilities and the regulations which are usually employed do not meet the requirements of a severe test, and business suffers.

The business of a factory sometimes grows at a gratifying rate, and the receiving and shipping facilities which were at first ample are perhaps not developed at a corresponding pace. An undue burden is sometimes put upon the railroads which serve the plants, whereby several shifts per day are necessary when one at first was sufficient.

Olympia's Doors Close on Most Successful Show

by

J. S. Critchley

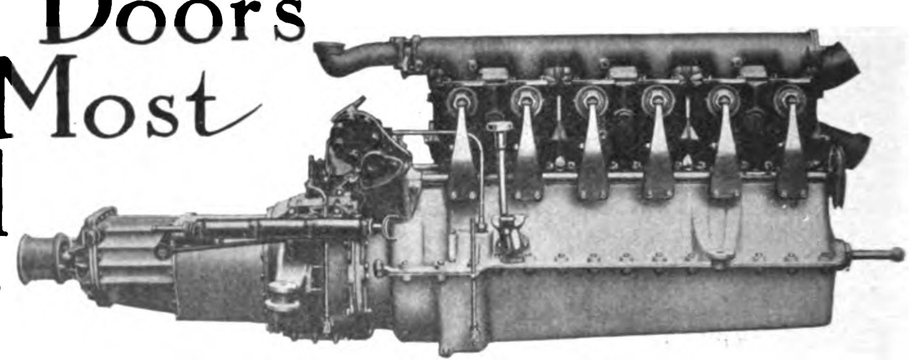

Fig. 1—View of the Lanchester six-cylinder motor, showing side valve levers

LONDON, Nov. 16—(*Special to* THE AUTOMOBILE)—The Olympia Show, which closed its doors today, has been an unparalleled success as regards the attendance of the public. At least 45,000 more people have visited the show this year than last, and over-crowding has been so severe that it has interfered with business to a considerable extent. On the days when the prices of admission have been raised to 5 shillings, and half a crown, the crowds have been even greater than on the days when the price was 1 shilling only, the reason of this being that people who really want to see things have selected the higher-priced days to avoid the crush. Those who have attended to seriously study the constructions have been very much hampered by the dense crowd. Among the manufacturers considerable dissatisfaction has arisen from the fact that the members of the Royal Automobile Club are admitted on presentation of their membership tickets. This has been the regulation ever since the show commenced. It is thought, however, that if members of the Royal Automobile Club were charged for admission there might be a little less crowding. Seeing that the club has only some 7,000 members, it is doubtful if this would make any appreciable difference, as probably not more than 1,500 of the members visit the show simultaneously.

One of the difficulties in getting to some of the stands is due to the fact that they are surrounded by the agents of the various concerns. In many cases thirty to forty agents will be dispersed round their firm's exhibit, and, as the stands are comparatively small, it is obvious that in many cases they are over-burdened with attendants.

The attendance has been greater than ever as shown by the following statistics:

	1910	1911	1912
Friday	10,954	12,539	14,322
Saturday	25,843	27,890	34,672
Monday	33,511	22,132	26,989
Tuesday	24,160	19,291	24,393
Wednesday	38,115	38,748	48,879
Thursday	29,728	36,765	39,739
Friday	27,292	39,832	33,470
Saturday	29,305	28,898	32,648
	218,908	226,095	255,112

Probably the private sales have never been less than this year, and this is entirely due to the inability of the purchasers in some cases, to even get to the stand they wish to visit. The provision of a bigger hall is every year more necessary, as the show has completel outgrown the capacities of Olympia.

Lanchester Improves on Details

The Lanchester company is making no changes in cylinder dimensions or horsepower. The two cars constructed by the Lanchester company are a four-cylinder, 4-inch bore and 4-inch stroke, and a six-cylinder of the same dimensions. The motor is shown in Fig. 1. There are, however, improvements in detail, one of which is rather notable. The object of this improvement is to render the four-cylinder engine as smooth in its running as the six-cylinder and to do away with engine vibration. This anti-vibrator consists of two spindles running at right angles to the crankshaft, and at twice its revolution. The spindles are provided with balance weights, which do not exceed 12 pounds. At high revolutions these balance weights tend to compensate the unbalanced force of the motor.

A self-starter is also fitted to one of the models. This is of the electric type. The dynamotor is driven by an inclosed silent chain from the rear end of the countershaft. The dynamotor charges a 32-volt accumulator, an 8-volt current being provided for for lighting purposes. The starting is effected by sliding the gearshaft and intermeshing gears between the forward end of the armature shaft and the flywheel of the motor. Coupled to the self-starting control lever is an arrangement for retarding the ignition simultaneously. Fig. 1 illustrates the six-cylinder engine and gear.

Benz in Remarkable Test

Practically no change has been made in connection with the Benz productions. The 12-30 Benz with a bore of 72 millimeters and stroke of 120, is a car which has achieved a considerable amount of notoriety on account of its efficiency. The car is very speedy and on a trial at Brooklands ascended the 1 in 4 grade with four passengers at a speed of 11 miles an hour. The dimensions of the car are as follows:

Length of frame from dash	8 ft. 2 ins.
Breadth of frame	2 ft. 6 ins.
Wheel base	9 ft. 6 ins.
Wheel track	4 ft. 2 ins.
Overall length of complete car (hood down)	14 ft. 6 ins.
Overall width of complete car	4 ft. 9 ins.
Height of complete car (hood and screen down)	4 ft. 6 ins.
Weight of chassis	14 cwt.
Weight of complete car	20 cwt.

The engine cylinders are cast monobloc with water jackets and internal gas passage forming an integral part of the casting. The camshaft is driven by silent chain with the valves in line. The cylinders are arranged over the crankshaft offset in the direction of rotation. The crankshaft is fitted with three bearings and is of specially large proportions enabling the engine to be run at very high speeds with freedom from periodic vibration. Lubrication is of the combined pressure and splash system, the end of the connecting-rods dipping into troughs which are fed from the overflow of the main bearings. Ignition is effected by the Eisemann self-advancing magneto, and the cooling system is on the thermo-syphon principle. From the flywheel the power is taken by means of a leather clutch fitted with springs beneath the leather. To effect easy changing of speeds a clutch stop is fitted, which is shown in Fig. 3. This consists of a disk working against two leather-faced adjustable pads. The shaft between the clutch and the gearbox is supplied with two universal joints. It will be noticed that there is no cramping of the various parts and that the removal of the gearbox or clutch is a comparatively easy matter. The gearbox is fitted with four speeds, and is of the jointless one-piece casting type. Stuffing boxes are fitted to the shafts to retain the oil.

Power is transmitted from the gearbox to the rear axle by means of a propeller shaft completely inclosed in a tubular casing. Radius rods are fitted, and the back springs double shackled.

For the 1913 season the Germain company is producing the following models: 20 horsepower with Silent-Knight engine manufactured by the Daimler company, Coventry, Fig. 2; 15 horsepower with poppet-valve engine, monobloc cylinders; 14 horsepower, 18 horsepower, 20 horsepower, 28 horsepower with poppet-valve engine and separate steel cylinders with brass water-jackets.

It is interesting, in the first case, to notice that this company has adopted the Knight sleeve-valve engine. This engine has the following dimensions: Bore of cylinder, 90 millimeters; stroke of piston, 130 millimeters, and the R. A. C. rating is 20 horsepower. The lubrication of the reciprocating parts and journals is effected by the Daimler semi-mechanical system which insures an adequate supply of oil while preventing over-lubrication and its attendant evils. The regulating device is inter-connected with the throttle regulator, the oil supply varying with the speed of the engine. The Zenith carbureter is fitted in conjunction with pressure feed. Cooling is effected by a worm-driven centrifugal pump, together with a radiator of ample capacity and a belt-driven fan. The ignition is by Bosch dual system with worm-driven magneto,

Long Pistons in 15-Horsepower Model

The 15-horsepower engine with monobloc cylinders is of particular interest and this engine will be described rather fully. In the first case the cylinder diameter is 80 millimeters and the piston stroke 140 millimeters, which is according to R. A. C. rating 15.9 horsepower. The pistons, though light, are exceptionally long—126 millimeters—and the cylinders are offset to the extent of 22 millimeters. It has been necessary to slightly slot the pistons on one side to clear the connecting-rod. The cylinder for the same reason has cast grooves on one side, a practice that is now common. Four piston rings are fitted, and this for pistons so small in diameter is somewhat unusual. The connecting-rods have a length of 290 millimeters and in comparison with the pistons are somewhat heavy. The crankshaft has three bearings, 70, 60 and 8 millimeters in length, respectively, the last mentioned having the bearing on the flywheel end. The diameter of the crankshaft at the two forward bearings is 40 millimeters and at the rearward bearing 45 millimeters, while the crankpins are 60 millimeters long by 40 millimeters diameter. It is noticeable that the camshaft chain-driven wheels are placed not at the forward end of the crankshaft, but at the back and near to the flywheel. Outside these wheels is a large ball bearing which is intended to support the weight of the flywheel. It seems that this is a position in which a ball bearing can be used with advantage for it would here receive little or none of the actual shock of the explosion. The crank wells are 20 millimeters wide against the bearings and the unsupported webs have a width of 26 millimeters. The front end of the crankshaft has a pulley to take a flat belt for fan driving.

Turning now to the camshaft, it will be seen that this has in all five bearings, three of them being plain journal bearings of large diameter and the remaining two ball bearings. The shaft has a diameter of 24 millimeters, and the cam width is no less than 25 millimeters, but this is partly due to the fact that no rollers are used on the tappets. There are two thimbles, one fitting inside the other; there is a long coiled spring, Fig. 13, that tends to separate them and thus to make up any slight clearance that may exist in the valve operating mechanism. The arrangement is very simple and should effect silence in operation.

Germain Spark Plugs in Novel Position

There is a small worm on the camshaft for driving the oil pump in connection with the lubricating system, which will be described. The valves are arranged upon one side of the engine and have a diameter of 40 millimeters, the ports and gas passages being very free. There are covers over the valve springs, tappets, etc., and these are attached in a simple manner. The igniting plugs are not over the inlet valves, a point that is now almost universal, but are screwed in to the opposite sides of the combustion chamber at an angle of about 45 degrees. Most tests that have been made with regard to plug position have served to prove that when the plug is placed in the pocket near the inlet valve a slow-running and elastic engine is most easily obtained; it is not easy, therefore, to see why in the Germain engine this practice has not been followed. In the position shown, too, the plugs would appear to lose some of the advantage of the cooling effect of the mixture as the electrodes are in a pocket some inches from the point at which the mixture enters, although the violent turbulence of the mixture will tend to clear the plug pocket to a great extent.

The water-jackets are carried well down the cylinders and the valve pockets and passages are very well looked after. There is a ribbed exhaust carrier having at one part of it a short hood for supplying warm air to the carbureter.

In connection with the lubrication it may be said that the oil is contained in a special sump or oil reservoir contained in the lower half of the crank chamber. This sump is of novel design, being fitted with a splash plate or baffle which prevents the oil washing over the edge into the crank chamber. The splash plate slopes towards a hole in the center after the manner of a funnel, thus allowing the return oil to flow into the sump. In addition to passing through the usual gauze filter, the oil is made to flow into a well in the center of the sump where any remaining sediment is separated from it by gravity. A perfectly

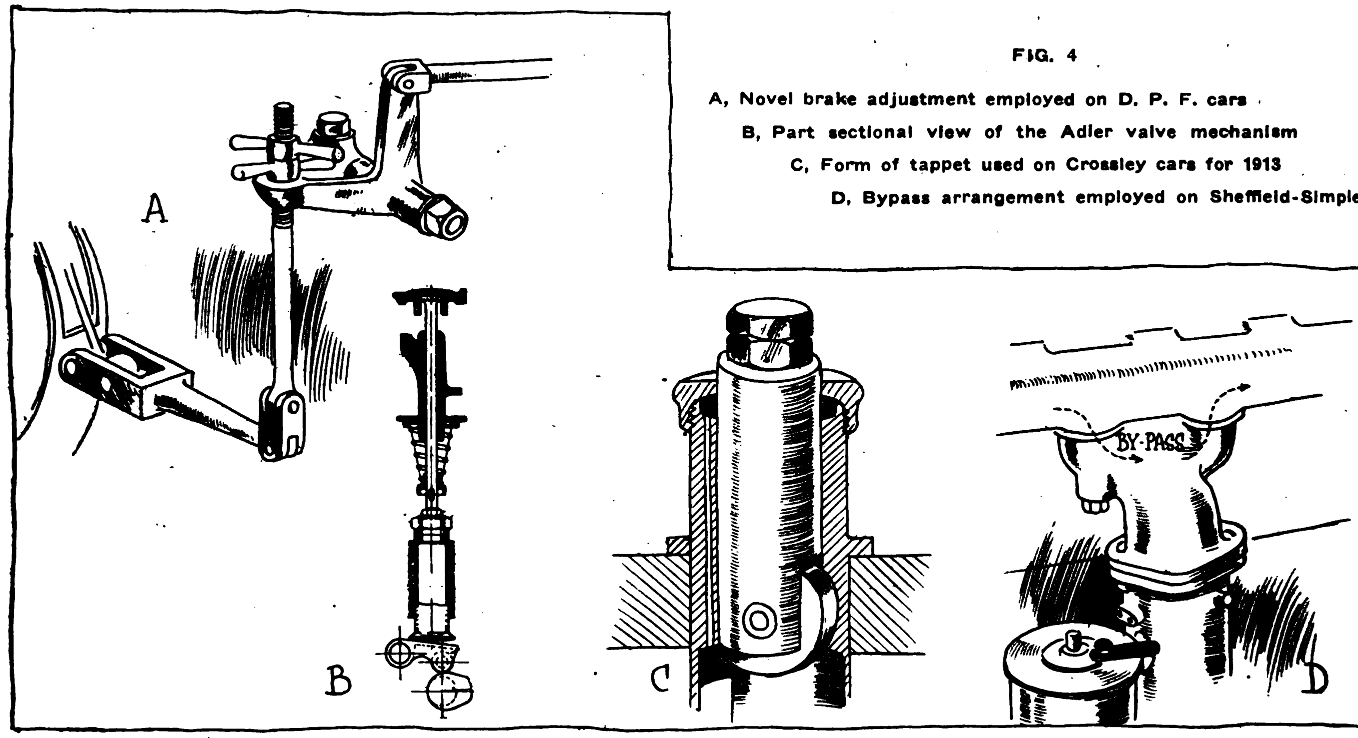

FIG. 4

A, Novel brake adjustment employed on D. P. F. cars

B, Part sectional view of the Adler valve mechanism

C, Form of tappet used on Crossley cars for 1913

D, Bypass arrangement employed on Sheffield-Simplex

clean supply of oil is thus obtained under all conditions and all possibility of the oil on the sump overflowing into the crank chamber and causing over-lubrication is entirely removed. The oil sump is approximately square in shape and has cooling ribs cast on its outer surface, which assist in keeping the main supply of oil cool and preventing its evaporation.

Fig. 13 shows an alternative type of tappet and it will be noticed that the principal difference between this one and the one described is that the coiled spring is replaced by a quantity of felt packing and that there are a series of thin steel washers contained in the bottom of the larger steel thimble. This is certainly a very novel feature and presumably would be more conducive to silence than the type of tappet previously described.

Felt Packing Makes for Silence

Presumably the felt packing will not only serve as a spring between the two thimbles, but will also in a great measure deaden or muffle any slight noise that might otherwise be due to some cause or other. It will be unnecessary, perhaps, to remind readers that felt or some very similar substance is used constantly to insulate running machines from the flooring to which it is bolted.

The engines of the other models retain for the most part the characteristic features of last year's designs. The cylinders are in every case of steel, machined from a solid forging, and surrounded by brass water-jackets, secured in a manner which makes any water leakage practically impossible. The use of steel for this purpose, although more expensive in manufacture, gives a cylinder which is entirely free from any danger of loss of efficiency through porosity, and one in which wear is reduced to a minimum. Also, the combination of this cylinder with a drawn-brass water-jacket of light gauge produces an engine far lighter than it is possible to obtain with cylinders of the ordinary cast type. The ignition is by Bosch magneto, an automatic advance device being included in the engine.

The new 20-horsepower model with separate brass jacketed cylinders of 92-millimeter bore and 150-millimeter stroke of piston has all the valves on the same side. The crankshaft is mounted on five bearings, that is to say, there is a bearing on either side of each cylinder. By reason of this the crankshaft remains exceptionally rigid under the heaviest loads. The lubrication system is similar to that employed on the other models, and a Zenith carbureter with pressure feed is also fitted. The ignition is by the Bosch D.U.4 type magneto, which includes an automatic advance device, and is driven, together with the water pump, from the camshaft by a worm gear.

The 20-horsepower Silent-Knight, 14-horsepower monobloc, 20-horsepower and 28-horsepower models are fitted with four-speed gearboxes, the other models having three speeds. In the 30-horsepower model, option is given of a three-speed box at a reduced price.

In the 14-horsepower, 18-horsepower and 28-horsepower models the inlet and exhaust valves are placed on opposite sides of the cylinders, the camshafts being operated by timing wheels of case-hardened steel running in an oil bath. These are finished by being ground together, and in this way perfect accuracy of tooth profile is obtained, and silent and efficient working assured. Forced lubrication is employed by means of a gear pump, worm driven from the camshaft, the oil being conducted to the main bearings through separate pipes, and thence to the big end bearings through holes drilled in the crankshaft. The Zenith carbureter, in conjunction with a pressure gasoline feed, is also used for these models.

A somewhat striking feature is the size of the brake drum; the diameter is more than 13.5 inches and the width of the brake shoe is 2.1875 inches. The drum has circumferential cooling ribs upon it, and owing to the comparatively high speed of the drum, these should be effective.

Crossley Continues Two Models

The Crossley Motors Company, Ltd., is making no radical change for the coming season, and is continuing to construct the two last year models, namely, 15 horsepower, 80 millimeters bore by 120 millimeters stroke, and the 20 horsepower, 102 millimeters bore by 140 millimeters stroke. The following are the features of these cars for 1913:

In the case of the 15 horsepower, the cylinders are cast en bloc, and in the 20 horsepower in pairs. The 15-horsepower engine flywheel pit and gearbox are on the unit system. In the case of the 20 horsepower the gearbox is independently supported in the chassis on two tubular cross-members. Both engines are cooled by thermo-syphon circulation, and both are lubricated under pressure, the oil pump being fixed on the casing at the front of the engine and driven directly off an extension of the camshaft, the oil being drawn by the pump out of the sump, and forced through the hollow crankshaft to the journal

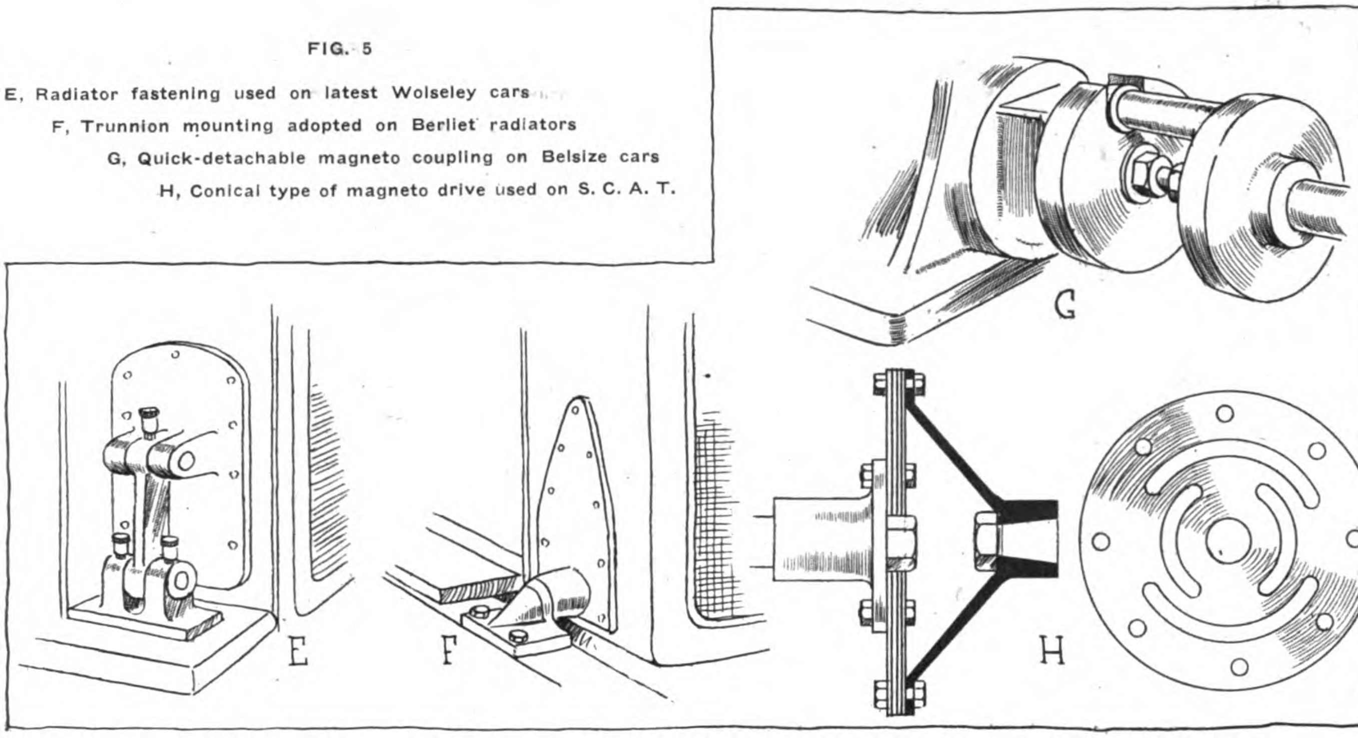

FIG. 5

and big end bearings. The pistons are fitted with three rings above the wristpin and no scraper rings are provided. The earlier Crossley models were fitted with the dashpot arrangement on the valve risers, the object of which was to keep the valve stems continually in contact with the adjustable set-screw of the tappet plunger. It has been found, however, that the solid plungers, Fig. 4, without the dashpot are in every way as silent as the results obtained from the previous arrangement. Chain drive for the half-time shaft and magneto is retained.

Clutch Stop a Crossley Feature

The drive for the engine gearbox is through a leather-faced cone clutch. The clutch runs on a spigot forming the extension of the crankcase, and is of the internal type. A modification this year consists in adding a clutch stop. The universal joint of the ring type couples the clutch to the gearbox, the bushes and pins of the universal joint being fitted with ball non-return type lubricators which prevents the oil being thrown on to the bushes by centrifugal force. The gearbox remains exactly as before, and has four speeds and gate control. The features of the gearbox are the generous dimensions of the ball bearings, gear wheels and shaft. A feature in construction which differs from ordinary practice is the fitting of the keys of the sliding shaft after the shaft itself has been ground, in other words, the keys are not solid with the shaft. The advantage of this method is that the portion of the sliding shaft on which the change speed wheels slide can be made absolutely true by grinding; on the other hand, there is a chance of the keys working loose. Another feature of the gearbox is that the constant mesh wheel on the clutch shaft is supported by a ball bearing on both sides, and is thus not overhung. At the back of the gearbox there is the usual brake drum and universal joint connecting the gearbox through the propeller shaft. This universal joint runs in a spherical torque ball which forms an oil bath. The brake is of the two-shoe cam-operating internal expanding type, and the brake drum is ribbed for cooling purposes. The propeller shaft is entirely inclosed in a steel torque tube bolted on to the center casing of the rear axle. With regard to the rear axle, the differential is entirely removable through the lid at the back, and is provided with an adjustment for accurately setting the depth of the engagement of the main crown wheel with the driving bevel. The brakes and the rear wheels are also of the two-shoe expanding cam-operating type.

As in former years, the cylinders of the Sheffield-Simplex are cast in sets of threes and the valves are upon one side. The cams do not operate the tappets directly, but there are radius links upon which the cam rollers are mounted and the links are drilled to secure lightness.

The cylinder has a diameter of 89 millimeters and the stroke of the piston is 127 millimeters. There is a bearing between every crank and an exceptionally long bearing at the back end of the engine. The pipe arrangement on the valve side of the engine is very neat and compact, the exhaust pipe gradually increasing in area as it nears the back end.

Briefly, the points to be taken note of in connection with this model are: a double-dropped frame providing low carriage entrance without sacrificing maximum road clearance. Ordinary three push pedal type of control; Lanchester type rear springing; neatness of exhaust and induction piping on engine; thermo-syphon with draft induced by fan flywheel; spherical bulged radiator; both foot and hand-operated brakes acting direct on to rear road wheels and all of the expanding type; the clutch is a multiple-disk type having a large number of flat plates; two independent sets of brakes are fitted, both acting upon large air-cooled drums on the back wheels; a special adjustment is provided for taking up wear without affecting the original position of levers on pedal; the live axle has a Lanchester or concave type of worm, and, finally, all important power transmitting parts are manufactured from a steel specially developed by a leading firm of Sheffield manufacturers, providing a hard-wearing surface and exceptional strength, as shown by the following results of an official test taken by the Sheffield Testing Works, Ltd.:

Tensile strength	122 tons per square inch
Elastic limit	115 tons per square inch
Elongation	11 per cent. in 2 inches

Vinot Has Chain-Driving Camshaft

The Vinot car represents one of the most satisfactory designs in European construction for a light medium-powered car. The firm specializes in two models, namely, a 12-14 horsepower, 70 millimeters bore by 110 millimeters stroke and a 15-20 horsepower, 80 millimeters bore by 130 millimeters stroke. With both the cylinders are cast monobloc, all valves in line and camshaft driven by inclosed chain. The magneto and pump are placed on the opposite side to the carbureter and driven from the camshaft. Lubrication is of the forced variety, both to the main bearings and to the connecting-rods, the oil pump being driven on the camshaft by an eccentric. In connection with the oiling system the usual test-cock is fitted to the base, but in addition there is provided a metal dipping rod which, when it is withdrawn, shows by notches cut thereon the amount of oil in the sump. A gauge of this description is also used by the De Dion company.

The clutch is of the leather type and is fitted with six semicircular plate springs between the leather and the face with bolts extending through the rim by which these springs can be adjusted. Further, the clutch can be so arranged that it can be dismounted without disturbing any other part of the mechanism. Between the clutch and the gearbox a universal joint is fitted.

Hexagonal Shafts Used in Gearbox

The gearbox is provided with three speeds, and the shafts are finished to a hexagonal section, which, it is claimed, is stiffer than a round shaft of the same weight. The primary shaft runs in three sets of ball bearings, two of these being placed at the forward end, which take up the pressure when the dog clutch takes up the direct drive on top gear.

A feature of the construction is in connection with the lubricating arrangement, a tube being carried from the trunnion to the outside of the frame where a grease cup is fitted. The grease cup is further arranged so that a grease pump can be screwed on to the end of the pipe. This is one of the small refinements demonstrated by the present show. All the greasers of the Vinot car are placed in accessible positions. With many cars in order to lubricate certain parts either the floor-boards have to be removed or it is necessary to attend to the grease cups from below.

The Adler valve is illustrated in Fig. 4. The characteristic feature of the construction of the valve is that from its seating it is extended in a cylindrical form. By this means the valve can be lifted before the gas enters the cylinder, and it can be moved more slowly than the ordinary constructed valve, and vice versa, the valve can be closed more slowly. This slow start and termination of the valve movements with simultaneous shutting off of the aperture affords the possibility of compensating the interstice between the valve tappet and valve stem, and further of placing the valve on its seat noiselessly. To this there is added the action of the roller lever, interposed between the cam and the tappet, which also effects the gradual starting and termination of the valve motion. The roller lever, which pivots on a fixed shaft, carries the tappet and has at its upper end the setscrew terminating in a hexagonal, which is secured by a nut after the adjustment of the required play between the tappet and valve stem.

The Adler clutch is of the leather-cone type internally operated. Beneath the leather, leaf springs are fitted at three points. A characteristic feature of this clutch is that it can be easily dismounted in the following way: The bolts coupling the clutch to the flange are first removed, after which the bolts are screwed up, which draws the spring case into the clutch cone. This reduces the distance between the flange of the flywheel and the flange of the gearshaft, so that the entire clutch group, with the clutch ring, can be taken out.

There is a by-pass in the Sheffield-Simplex exhaust pipe, Fig. 4, which carries a portion of the exhaust gases round the upper part of the inlet pipe of the engine.

The Wolseley radiator, Fig. 5, is not fastened direct to the frame, but is anchored by short arms pivoted at either end. Thus when one side of the frame rises somewhat higher than the other, the links allow for the movement and there is no straining of the radiators and consequently leaks are not likely to be developed.

The Belsize magneto coupling, Fig. 5, consists of two disks, one having a pin screwed into it and the other a notch or slot in which the pin engages. The coupling allows for a small amount of lack of alignment without any undue friction in the bearings.

To permit a certain amount of freedom to the Berliet radiator it is mounted upon trunnions, Fig. 5. Thus in the case of frame distortion the radiator is not strained.

Spring Drive Magneto on S. C. A. T.

The magneto spring coupling on S. C. A. T. cars, Fig. 5, consists of a series of circular steel spring plates fixed to the magneto driving shaft; these are cut out as shown in the end view of one of the plates. A cone-shaped casting is fitted on the magneto spindle and this is secured to the outer diameter of the plates. Thus a fair amount of flexibility exists. A similar type of coupling is used between the flywheel and the multiple-disk clutch casing.

The armature of the Bosch starting magneto is geared up six to one to the starting handle; it is, therefore, obvious that a very slow pull-up of the latter results in a fat spark occurring at the plug. It will be understood that the starting magneto is only

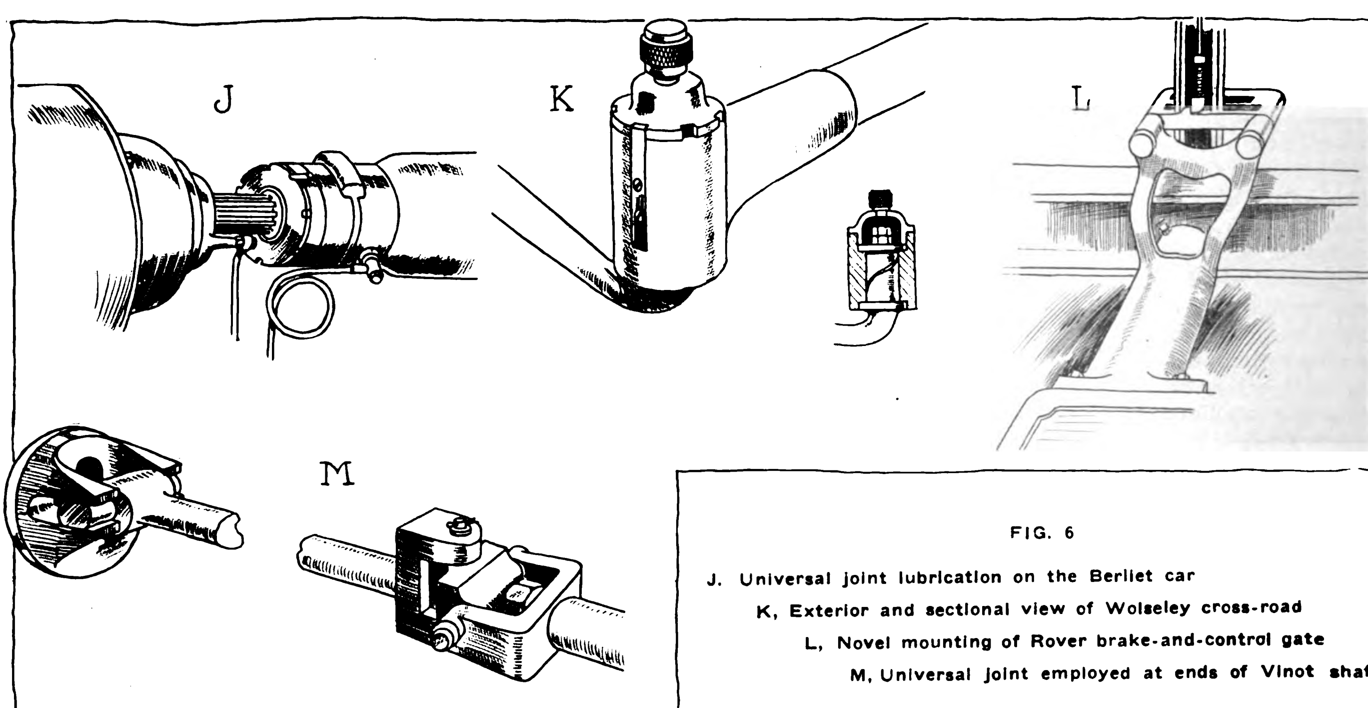

FIG. 6

J. Universal joint lubrication on the Berliet car

K, Exterior and sectional view of Wolseley cross-road

L, Novel mounting of Rover brake-and-control gate

M, Universal joint employed at ends of Vinot shaft operated when the engine is actually being started, and remains quite passive in ordinary running. If the engine be just warm a casual turn in either direction of the starting handle is enough to set it in motion.

The Berliet universal joint, Fig. 6, behind the gearbox is novel because it is kept supplied with lubricant from the engine; the front end of the propeller shaft is serrated so that a telescopic joint is formed at this point in addition to the universal movement permitted by the main joint. The oil feed to the back axle is led into the front end of the torque tube in which the propeller shaft is supported by a ball bearing. The shaft itself carries a little worm wheel just in front of this bearing, which acts as a kind of turbine and throws the oil entering the tube, just in front of this wheel, onto the ball race behind it. Thence it reaches the bevel gear and differential casing by gravity.

Fig. 7 illustrates the fan drive and pump of the S. P. A. car. The fan is provided with a free wheel arrangement to take away jar should the gears cease to run. The pump body is cast integral with the cylinders from which the water flows directly to the jacket. The turbine pump is fastened to the same spindle as the fan.

Darracq clutch withdrawal gear, shown in Fig. 7, has two ball-bearing rollers having their axles vertical, which are fixed to the fork ends of the clutch disengaging lever.

The Crossley brake-rod adjustment, Fig. 8, provides a simple and handy method of lengthening or shortening the brake-rod, and a glance at the illustration will render any description unnecessary. The angular position of the Crossley brake lever can be altered by slacking the nut, shown in Fig. 8, and disengaging the serrations. When the nut is tightened the serrations provide a certain grip.

Clutch Pedal Geared to Shaft

Fig. 9 shows the clutch mechanism of the D. F. P. car. With this engine the clutch is of the internal type, and in order to get the necessary movement the clutch pedal is geared to the shaft carrying the clutch disengaging fork.

A feature of the Waverley car is its rear suspension, Fig. 10. Forward springs of the usual semi-elliptic type are used, but at the rear two quarter-elliptic springs are fitted at each side. These are superimposed and spaced about 4 inches apart. Nearly flat, they give ample vertical movement, and can act as torque and driving members without reducting their efficiency as springs.

Fig. 11 illustrates the brake adjustment on the four-cylinder Standard car, 89 millimeters bore by 133 millimeters stroke. With this brake adjustment the adjusting devices are brought outside the frame, a practice which makers are adopting, namely, Deasy, Maudslay and others. It will be noticed that there are two adjustments, one for the grip, the other for positioning the lower shoe. It is quite unusual to find these two adjustments provided for in this manner. The grip adjustment is effected by the wheel A, which is keyed to the shaft B. At the end of this shaft a bevel wheel is provided, gearing with a bevel on the screwed shaft C, the rotation of which draws the shoes together. The positioning arrangement is effected by the thumb screw D, which by means of the screwed shaft E raises the bell crank F upon the lower arm of which the lower brake shoe rests.

Argyll Collapsible Tank Filler

The Argyll filler for the gasoline tank, which is on the dashboard, is made collapsible, Fig. 12, thus the filling process is very much facilitated. A neat and simple form of quickly detachable cap is also provided and the action of this is clear from the figure.

The J. B. shackle bolt is turned from the solid steel bar and the head of the bolt is bored out to form the grease box. The brass cap is so constructed that it can be slipped on to the grease box with a gentle pressure. There are no threads, either on the grease cup or cap, so that the annoyance of a crossed or worn thread does not exist. Four little steel balls fitted in the cap operate in such a manner that no amount of vibration will allow the cap to move back.

To lubricate the bolt the grease cup and cap is filled in the ordinary way, then the cap is slipped over the cup and gentle pressure from time to time on the cap, as the grease becomes exhausted, will keep the bolt properly lubricated.

The Thompson-Bennett exhaust car heater consists of an aluminum box let in flush with the floor of the car and the heat is derived from the exhaust by diverting the gases into the heater and thence to the atmosphere. A heat regulator is attached so that the temperature can be graduated at will or shut off entirely if necessary. This valve can be operated on the heater itself. As an alternative an independent regulator can be supplied and arranged in any suitable position on any part of the automobile.

The heater is simple to fit. The exhaust pipe is tapped at any convenient place either before or behind the muffler. It is un-

necessary to dismount muffler or pipes, as the valves clip on. There are six possible inlet or outlet positions, any two of gas-tight flanges. This greatly simplifies the operation of fitting the heater on the car.

The Rex induction pipe jacket has been designed to overcome the difficulty that is sometimes met in connection with types of carbureters having no warming jacket. The air that is drawn into these from some hot part of the engine sometimes becomes cooled by passing through long pipes. The Rex consists of a hollow flange-shaped fitting which is intended to be secured between the lower flange of the induction pipe and the top flange of the carbureter. Screwed into the jacket, one at each side, are two elbow pieces, and to these are coupled inlet and outlet pipes connected to the exhaust branch of the engine, so that a portion of the hot exhaust gases passes through the space within the jacket. The latter is shaped, as to its internal bore, with the serrations increasing the area of the metal, which, becoming hot soon after the engine is started, warms the passing mixture, so tending more completely to vaporize the gasoline before it reaches the engine. It should perhaps be pointed out that the freezing zone, namely, that portion of the induction pipe upon which frost appears when the mixture is unwarmed, is usually immediately above the mixing chamber of the carbureter and that it is at this point where the Rex jacket is intended to be fitted.

A survey of the exhibits gives rise to observations which may be summarized as follows: Monobloc castings are greatly on the increase. With many of these there is an inclination to cast the exhaust passages within the cylinder casting. This is specially noticeable in the Italian designs. It is very doubtful if the casting of the exhaust passage within the cylinder casting is a useful or proper construction, and it would seem far better to cast the exhaust pipe separately with four leads from the cylinders, which are generally adopted by British manufacturers. In one case with a six-cylinder engine cast in two pairs of three each, the inclusion of the exhaust passage within the main casting proved to be very faulty, and led to distortion of valves. In this case, however, thermo-syphon cooling was relied upon for the water circulation, and the majority of engines in which the exhaust manifold is not separate from the cylinders are fitted with pump circulation.

There seems to be a slight tendency towards the increase of cylinder bores, while crankshafts have undoubtedly increased in size. This leads one to the conclusion that periodic vibration is due to a large extent to over-strain on the shaft.

In very few instances were any means provided for cleaning the top of the piston and combustion head. With the majority of engines the only method of removing carbon deposit in a thorough manner is to take the cylinders off altogether, or one of the many chemical or oxygen processes.

As surmised previously, no new type of valve was exhibited. There is renewed evidence of the pains which have been taken in rendering the poppet valve engine reasonably silent. The Adler valve, B, Fig. 4, is a typical example.

The total number of cars exhibited at Olympia is 533. The countries of origin are as follows: Great Britain, 227; France, 163; Germany, 41; America, 34; Italy, 30; Belgium, 23; Switzerland, 6; Austria, 6; Holland, 3. This list includes not only vehicles exhibited by the manufacturers, but also includes those exhibited by various coach-building firms desirous of showing their work under favorable circumstances.

During the progress of the show Brooklands Track has been fully engaged, and some quite remarkable speeds have been attained. In the first place Christiaens, on a six-cylinder Excelsior car, 110 bore by 160 millimeter stroke, equalling 9,123 cubic centimeters piston displacement, beat the 50 miles world's record. His time was 29 minutes, 18.45 seconds, equalling 102.36 miles per hour. The half-mile was done at the rate of 108.3 miles per hour, and the one mile at 106.86 miles per hour. These figures, good as they are, were, however, on a recent trial badly beaten by Percy Lambert, with a four-cylinder Talbot car, 101.5

bore by 140 millimeter stroke, cubic capacity 4,531 cubic centimeters. In this instance the half mile was run at a speed of 113.28 miles per hour. The kilometer at 112.81 miles per hour, and the one mile at 111.73 miles per hour. The weight of the car with fuel, water and driver was 2,250 pounds. It was, therefore, obvious that the engine must have been developing quite 80 horsepower. The engine was in no way specially designed for racing purposes, but is one of the standard Talbot 25 horsepower motors. The carbureter was of the Stewart Talbot type, but of a larger size than that usually fitted. The tires were Palmer 820 by 120, which are now becoming quite standard tires in connection with Brookland records. The B. N. D. brand of steel piston and connecting-rods were used. The connecting-rods are of circular section, and only 1 millimeter thick. This gives one an idea of the extraordinary quality of the steel used. The Derihon shock-absorbers were fitted. These are quite a new type, and are on the principle that the suspension spring is free to move upward or downward from its normal position, and be checked only upon the return movement which follows this upward or downward displacement of the spring.

Digest of the Leading Foreign Journals

(*Continued from page 1162.*)

The approximate formula for the indicated horsepower of an engine is

$$\text{(2)} \qquad HP = \frac{S \times C}{60 \times 75} \times 2Np_i$$

in which S is the piston area in square centimeters, C the stroke in meters, N the number of revolutions, p_i the mean indicated pressure.

If f is the coefficient of the indicator spring in millimeters per kilogram of pressure, the mean indicated pressure is derived from equation (1) and has the value:

$$p_i = \frac{nk}{lf},$$

and equation (2) becomes:

$$HP = \frac{S \times C}{60 \times 75} \times 2N \times \frac{nk}{lf}.$$

Of all these values, it is noticed, the planimeter reading n is the only variable for the same engine [running at the same speed], so that, for this condition, one can write:

$$\text{(3)} \qquad HP = Kn,$$

K being a certain value with which the unit area of the planimeter can be identified by adjustment of the tracer arm.

[The author has mainly steam engines in mind, but the simplification seems applicable in practice to gasoline motors as well, if N is also singled out as a variable factor.—ED.]

If x is the coefficient corresponding to the data of the engine and k the actual planimeter unit, one has evidently: K equals $x - k$, and, to get a simple value for K, it suffices to adjust the planimeter unit on the basis that:

$$\text{(4)} \qquad k = \frac{K}{x}$$

With such an adjustment of the planimeter, the horsepower can thus be read directly from the planimeter on the basis of equation (3) [and allowance for variations in the engine speed may be made by means of an additional factor.—ED.]

Still more time may be gained by making use of rubricked paper, on which the diagrams are placed successively in the same position. The planimeter can then be held in the same position, and it suffices to take one reading at the beginning of the tracing of the diagrams and one at the end and to divide the difference between the two figures by the number of diagrams, thus obtaining without finicky calculations the mean indicated power which it is the object to ascertain [still on the supposition that the engine speed does not vary].—From *La Technique Moderne*, November 15.

Gotham Is Building 45 New Fire Houses

(Continued from page 1153)

of the contract and the rest of the order is scheduled to come along at stated periods thereafter and the actual installation will commence shortly.

The first lot of hose wagons, consisting of five units, has been delivered and the story of the test to which they were submitted reads like a road race. The cars start from Broadway and Fifty-seventh street, work north through traffic to Van Cortland Park, swing east to the Concourse and thence south on the Concourse through the heart of the Bronx and back to the point of starting.

In order to cover this course of 20 miles in an hour, it is necessary to touch a speed of 35 miles an hour once in a while. On the Concourse the maximum speed test is applied and the car must maintain a speed of 30 miles an hour over at least 1 mile. Such speed on solid tires is quite a strain on cars and men.

The motor is of four cylinders 4 1-2 by 5 1-2 and rated at 32 horsepower. The fire-fighting equipment is similar to that in use in the department. There is no material variation from the prevailing type of bodies.

These wagons will be used where quick action is the prime essential. It has been found that fire losses mount up geometrically in the ratio of delay in extinguishing the blaze. Mrs. O'Leary's cow kicked over a lantern which started the conflagration that destroyed Chicago. If the late Mrs. O'Leary had summoned the fire department and if the fire department had rushed one of the new hose wagons to the historic barn with a charge of chemical extinguisher, the history of the republic might have been changed. Measured in minutes saved, the efficiency of a fire department equipped with swift wagons fitted for fighting and conquering small blazes is vastly higher than where time must be lost in getting the heavier apparatus into action. Minutes literally mean millions in fire department terminology.

The next lot of apparatus under contract consists of twenty-eight steam fire engines drawn by tractors. These are to be furnished by the American-La France company. In bidding for the job this company had an advantage in that it specializes in fire engines. The tractors are to be of the two-wheel type driven by four-cylinder, four-cycle, water-cooled motors capable of developing a speed of 25 miles an hour and a sustained speed of 20 miles an hour for at least an hour through city traffic. The recommended standards of the S. A. E. are specified for the guidance of bidders. One feature of this lot of apparatus is that the specifications require that the tractor shall be easily detachable from the fire engine so that in case of failure of the propelling power or for other reasons horses may be substituted with minimum loss of time in emergencies.

An alternative tractor, the generative power for which shall be furnished by a 40-horsepower gasoline engine producing electric current for final drive, which must conform to the speed tests required of the foregoing type of tractor, is allowed under the specifications. The contract was let August 15 and the first block of five is due in 120 days from that date. The remainder must be delivered within 120 days thereafter.

The contractor is obliged to guarantee the machine for 3 years after delivery against the results of poor material or poor workmanship. The contractor has given a bond to the city amounting to half of the contract price conditioned upon the terms of the guarantee.

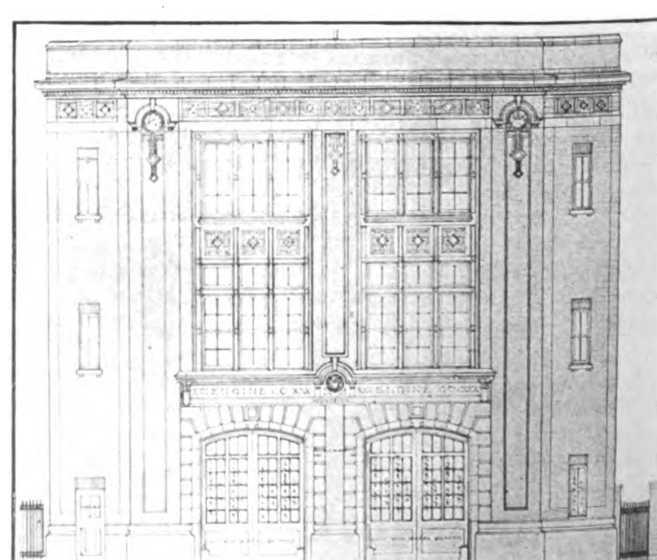
The contract just let for the tractor trucks provides for motors of the same general type as those called for in the case of the steam fire engines. The specifications call for automobiles standardized under the S. A. E. recommendations. The same option is given under them to supply gasoline generators with final drive by electricity. The tractors must be able to cover 20 miles within an hour through city traffic.

The trucks must all be delivered within 300 days of the execution of the contract, but some of them must be ready in 180 days.

Eighty-five Pieces in Apparatus Order

The whole order for new equipment amounts to eighty-five pieces and is not sufficient to supply the needs of the new houses. It will be necessary to purchase and install somewhere in the neighborhood of $500,000 worth more apparatus before the full capacity of the houses is filled, but in the meantime there will be enough of the new machines in daily service to test out the main idea underlying motorization.

This order is not in present contemplation, but will probably be taken up during 1913. If the new equipment answers requirements the displacement of horses will probably commence on a permanent basis not later than the beginning of 1914. It will not be on a wholesale scale such as might be indicated by the present additions, but will be accomplished gradually as the veteran horse-drawn equipment shows signs of faltering.



Bronx double house, 8 feet narrower than old type

The shadow of doubt as to the complete success of the present plans for motorization is founded upon some of the experiences of the past when makeshift mechanism failed to justify preconceived hopes. On the face of the specifications and contracts awarded for the new equipment this doubt appears to be unjustifiable, particularly in view of the fact that it has been definitely proven that the horse is extravagantly inefficient in long distance work.

The chief faults that have been found with relation to the automobile equipment that has been installed by the department, are lack of speed in some of the pieces; and the tendency to break down either through accident or otherwise. Part of the responsibility must be laid at the doors of the apparatus and at least a large part to the inexperience of the men who handled it.

In order to correct the first fault, the department has striven to secure better settled apparatus and to do away with the latter objection, it has installed a school of instruction that is designed to convert a plain fireman into a competent chauffeur and mechanic. This school turns out classes of graduates in 90 days and has been extraordinarily active in preparing for the reception and installation of the new machinery.

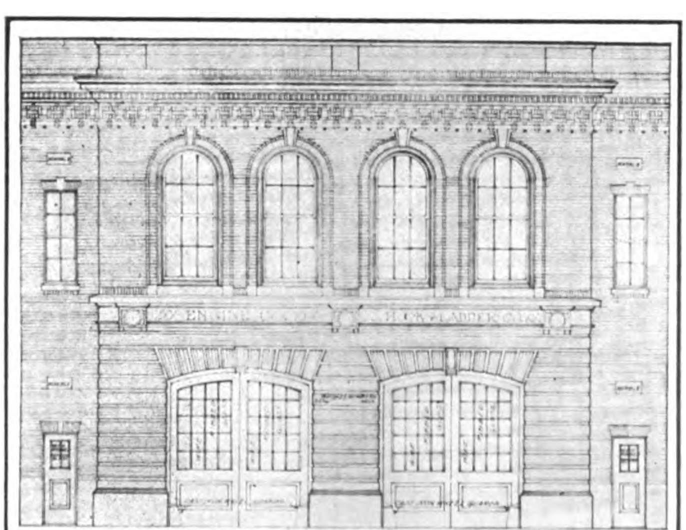
The original plan of the department included provision for a big municipal automobile factory. It was intended to erect a repair plant at a cost of $1,000,000 and to provide for manufacturing at subsidiary plants. The whole cost of operation was estimated at $3,000,000. But the authorities who have the veto power in such matters refused to sanction the appropriation. In case the plan had been adopted the department would have been in position to manufacture its own apparatus but it was shown that the cost would have been too high and in any new project of such scope the chance for failure must be reckoned.

The orders for fire apparatus given by the department are by far the largest group of orders ever placed for automobile fire apparatus.

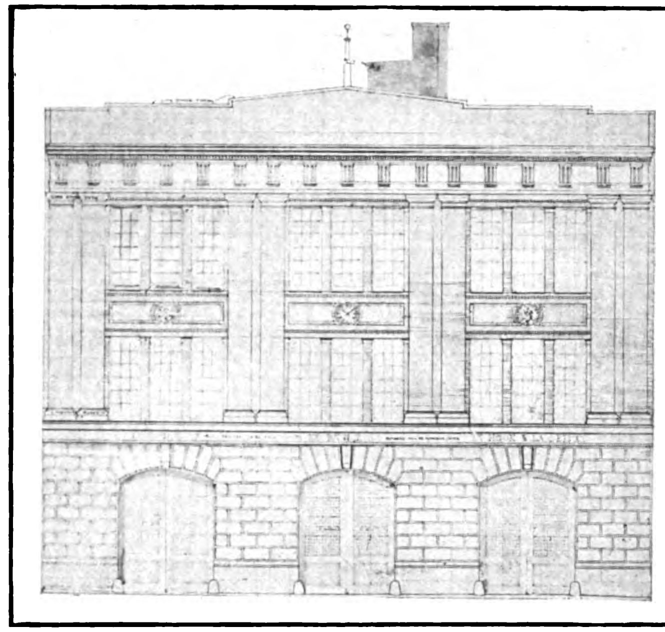
Harking Back a Decade

From *The Automobile and Motor Review,* December 6, 1902:

WITH a field of twenty starters and a number of outside cars, the Automobile Club of New Jersey held a successful hill-climb on Eagle Rock Hill on Thanksgiving Day. The day was gloomy and rain fell before and during the contest, turning the hill into a sheet of slippery mud. The course is 9 furlongs and the rise is 360 feet, maximum grade 17 per cent. W. J. Stewart in a Locomobile made the fastest time, covering the course in 2:58¾. The cars were classified by motive power and weight. The average time made was 4:43. Secretary S. M. Butler of the Automobile Club of America with a Mors timing instrument was in charge of the recording of the trials.



Big double house located in populous part of Queens



Triple house which will be equipped with six automobiles

Pronunciation of the names of French cars is still one of the puzzling things to American automobilists. De Dion-Bouton is about the worst thing for them to handle, but C. G. V. and Gillet-Forest are close competitors.

Col. John Jacob Astor has offered to subscribe $10,000 to aid in the construction of the national highway, on condition that the road run on the east bank of the Hudson, instead of the west bank. The suggestion has been made that the national government might be persuaded to appropriate $2,000,000 to construct a series of 40-mile stretches in each of the five districts comprised in the proposed road from New York to San Francisco

Mrs. J. B. Gibson of New York has just completed a 4000-mile tour through Europe in her new Panhard. She declares that the German officials were particularly pleasant in administering the laws and that she was not obliged to register in crossing the border or to carry numbers or initials to identify the car.

King Leopold of Belgium has commenced work on the preliminaries of a project to connect Ostend with Paris by a fine boulevard. Within the boundaries of Belgium the chief work required will be the substitution of macadam for the granite blocks that now extend from Ostend to Dunkergue. It is intended to have the road finished by July, 1903.

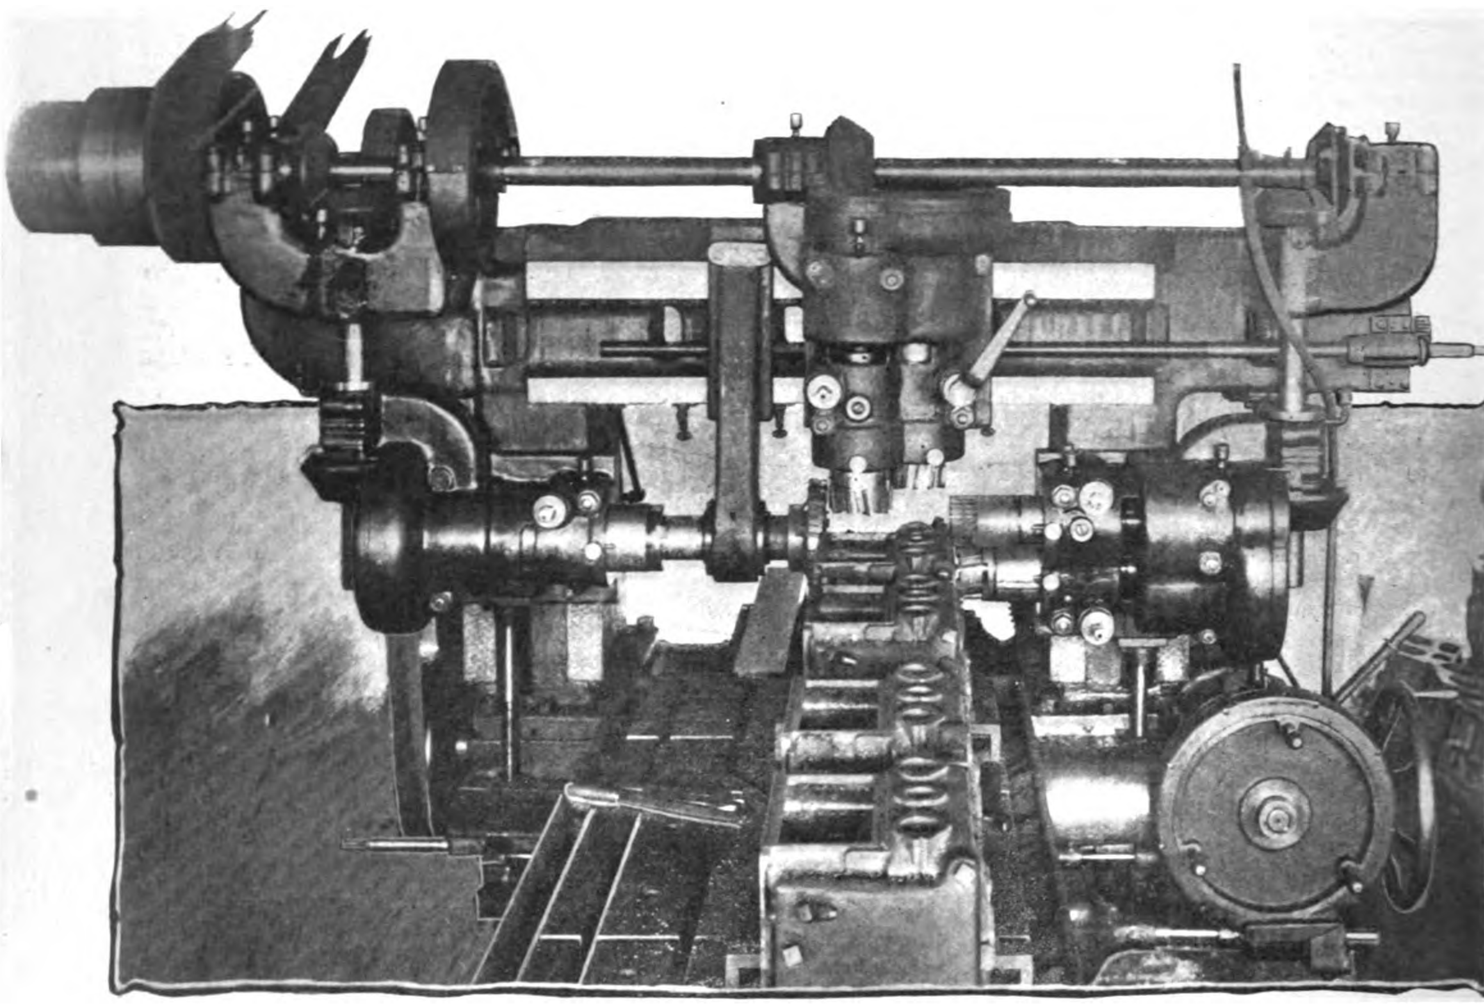
Kenneth A. Skinner of Boston recently made the round trip from that city to New York and return, 488 miles, in 35 hours elapsed time. He used an 8-horsepower De Dion, 1902 model.

The American idea of quantity production has been adopted by some of the French automobile factories. Jigs and templets have displaced manual skill at the Darracq and De Dion factories and a production of 2000 of the latter vehicles has been announced for next year.

F. T. F. Lovejoy, secretary of the Carnegie Steel Company at Pittsburgh, has let plans for the building of a private automobile stable or garage to cost $175,000. Mr. Lovejoy has eleven cars ranging all the way from a 40-horsepower racer to a small car for boulevard work.

Licensing of all drivers of motor vehicles is being discussed in New York City and an open hearing on the subject will be held shortly. The national organizations do not object to licensing the drivers, but they protest that the legislation should be by the state and not by the city.

A Winton car has been entered for the next Gordon Bennett cup race which will be run in Ireland or France next year.



Cylinder milling machine in use in the factory of the Velie Motor Vehicle Company, Moline, Ill.

THE above machine mills eight Velie cylinders at a time. This machine saves time and pays for itself in a short time—besides, and what is more important, it does the work well. In a factory where the uniformity of product and interchangeability is made an aim, a machine that will do the work rapidly is of special interest. This particular milling plant has a bed which supports four blocks of cylinders at a time. It has five simultaneously operating cutters which are shown in position. One man handles the machine. He can set up a job in 5 minutes and in 20 minutes more he will have milled a block of cylinders. This gives the Velie plant an output of 30 blocks of cylinders per day or enough for fifteen motors. Since the total production of the company is about fifteen motors a day this machine just takes chare of the output. The way the machine saves money is this: The Velie concern used to mill one block at a time. It took a longer time for the milling job and about the same time for setting up. In other words, 40 minutes was lost on each cylinder. 1,200 minutes per day's output—20 hours! This is equal to the work of two machines each working 10 hours a day. It is readily realized how valuable such a machine is as a time-saver.

NEW Timken-Detroit Building—Work on the new three-story and basement addition to the Timken-Detroit Axle plant, Detroit, Mich., is being pushed rapidly. The brick and steel structure is 60 feet wide and 275 feet long. On the first three floors the materials used in the manufacture of axles will be stored. On the top floor the general offices of the company will be located. This is the second big addition which has been erected within the year. The two buildings will increase manufacturing space about 33 1-3 per cent. New machinery worth $100,000 will be installed and 300 more men employed. The accompanying illustration shows the factory.

Chalmers Adds—The Chalmers Motor Car Company, Detroit, Mich., has begun the construction of a one-story brick addition to its factory.

Plant Has Fire—Fire which started with a gasoline explosion did $20,000 damage in the Nyberg Automobile plant, Chicago, Ill. No one was injured.

Anderson Resigns—Ross Anderson, for the past 3 years factory superintendent of the American Locomotive Company, Providence, R. I., has resigned his position to take effect January 1.

Brown Company's Plant—The John W. Brown Manufacturing Company, Columbus, O., will soon award the contract for the construction of a large addition to its plant. The company manufactures automobile lamps.

Moon Installs Machinery—The Moon Motor Car Company, St. Louis, Mo., recently installed a considerable amount of new machinery in its rear axle department. That department is now equipped to turn out a new rear axle every 20 minutes.

Lamp Company Builds—The Guide Motor Lamp Company has had plans prepared for the general contract for a new factory building to be erected in Cleveland, O. Plans call for a two-story and basement brick, steel and reinforced concrete building about 60 feet by 130 feet in dimensions, with cement and oak floors, electric lights, steam heat and a composition roof.

Kelsey Plant Damaged—The plant of the Kelsey Wheel Company, Detroit, Mich., was damaged by fire last month to the extent of $5,000. The origin of the blaze is unknown.

Michigan Steel's Addition—The Michigan Steel Castings Company, Detroit, Mich., has purchased a piece of property adjoining its present plant at Atwater and Guoin streets for an addition to its factory. The plot measures 92 feet by 190 feet.

Work on Dunkirk Factory—Work was begun on the construction of the plant at Dunkirk, N. Y., for the Niagara Gasoline Motor Company, which concern recently moved from Buffalo to that town. The building will be erected on Brigham road near the Lake Shore tracks.

Alco Factory in Detroit—It is reported that the American Locomobile Company is seriously considering the movement of the company's automobile factory from Providence, R. I., at Detroit, Mich., to manufacture the Alco car and that the committee is negotiating with the creditor's committee of the Grabowsky Power Wagon Company.

Racine's Radiator Company—The Perfects Radiator Company, of Chicago, Ill., has moved to Racine, Wis., and established a workshop on Fifteenth street and the Northwestern tracks. The production consists of motor car radiators, pumps, and other cooling devices. Twenty hands are employed and the force will be increased as needed.

Stove Works for Auto Plant—The Palmer-Moore Company, Syracuse, N. Y., has bought the plant of the Syracuse Stove Works in North Geddes street and will use the buildings to manufacture motor trucks. T. W. Meachem recently bid in the stove works buildings for $20,000 at a bankrupt sale. It is understood the creditors sold to the Palmer-Moore company at an advanced price. The property has been appraised at $75,000.

Lambert's Three Factories—In addition to the factories of the Waterman Company and the Monarch Electric Company, St. Lambert, Can., is to have a third factory which will engage in the manufacture of auto trucks. Mr. George Charrier, representing the Gearless Autotruck Company, yesterday purchased lots comprising about 10,500 square feet. On this it is the intention to erect a three-story steel and concrete building to be exclusively devoted to the manufacture of trucks for various purposes built according to an invention of Mr. Charrier.

Negotiating for Site—Negotiations are in progress for a site for a large plant to manufacture electric automobile tranmissions in Cleveland, O. It is stated that the new transmission, which can be attached to any gasoline motor-driven automobile, eliminates the present gear-driven transmission clutch, flywheel, heavy self-starter and the generator for the charging of batteries now part of automobile equipment. It has not yet been decided whether the new company will manufacture complete cars with the new electric transmission, or whether the gasoline and new electric transmission only will be manufactured and sold to makers of automobiles.

The Automobile Calendar

Shows, Conventions, Etc.

Jan. 2-10..........New York City, Importers' Salon, Hotel Astor, Importers' Automobile Alliance.
Jan. 4-11..........Cleveland, O., Annual Automobile Show.

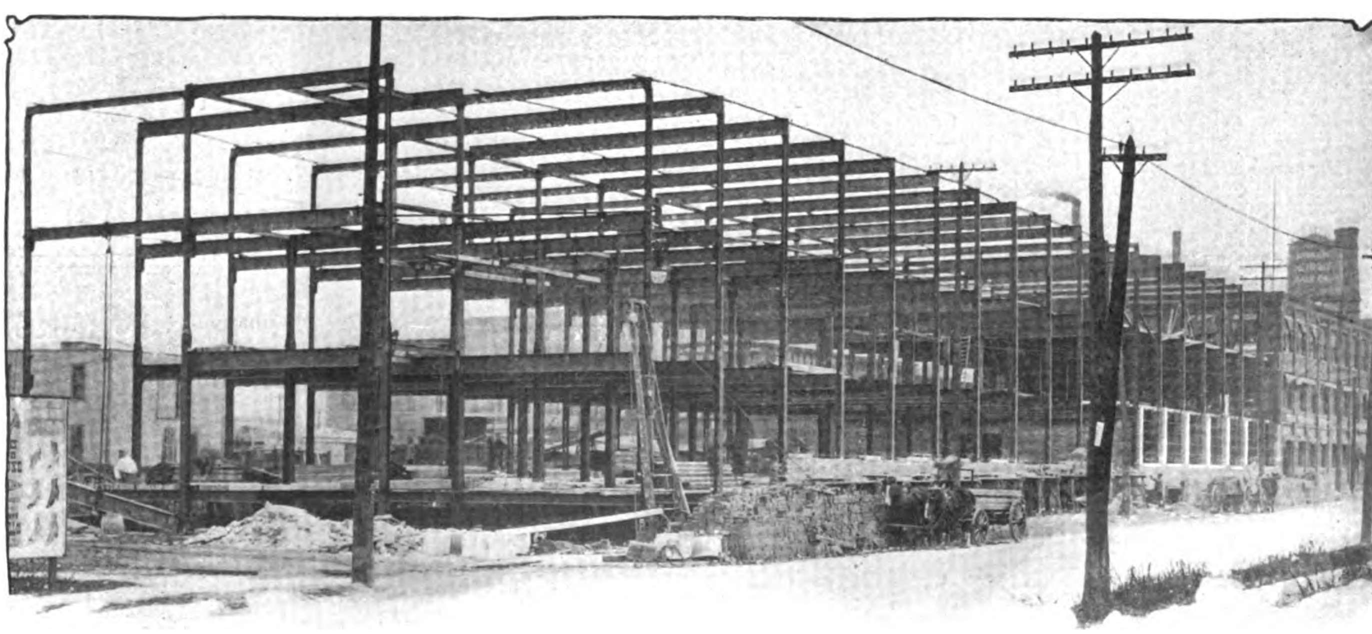
March 20-24.......New Orleans, La., Annual Show, N. O. A. D. A.
March 24-29.......Indianapolis, Ind., Annual Automobile Show.

Race Meets, Runs, Hill Climbs, Etc.

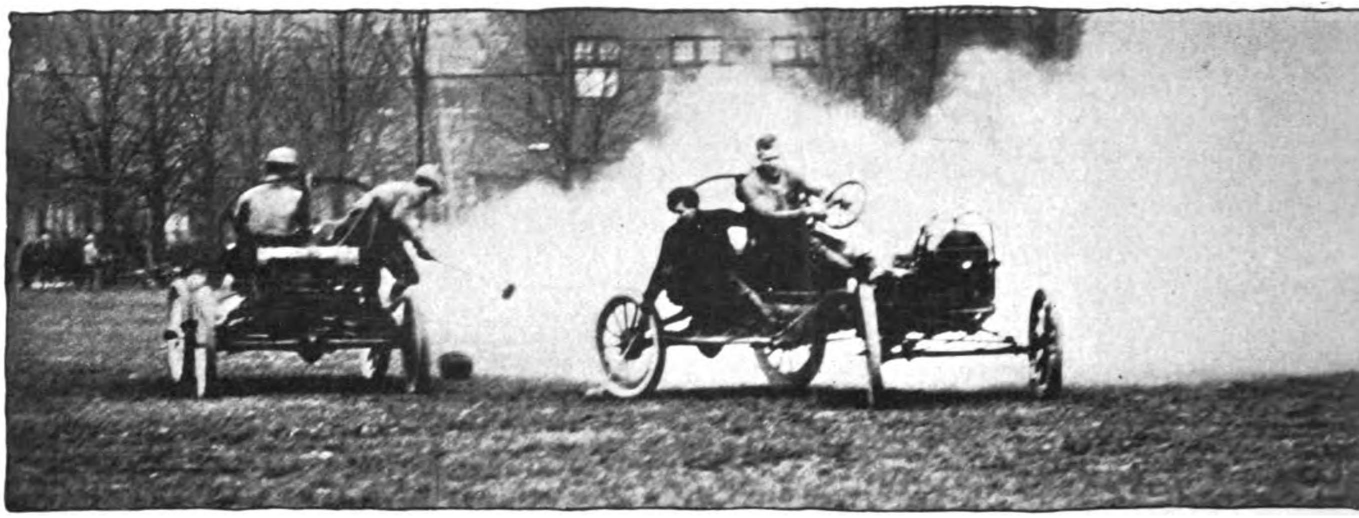
May 30...........Indianapolis, Ind., 500-Mile Race, Speedway.

Foreign

Dec. 7-22..........Paris, France, Paris Automobile Show, Grand Palais.
Jan. 11-22..........Brussels, Belgium, Annual Belgian Automobile Show, Centenary Palace.
March ....France, Sealed Bonnet 3000-Mile Run.
April ....Barcelona, Spain, International Exhibition.



Three-story and basement addition to the Timken-Detroit axle plant now in process of construction in Detroit



Trying out the new game of automobile polo in Detroit, Mich. The circular bridge steel support on the cars is for the protection of the drivers in the event of the machines turning turtle as they frequently do in this pastime

AUTOMOBILE Polo New Sport—Upsets, bursted tires, buckled wheels, marked the Detroit, Mich., trial game of polo with automobiles. This game has proved most exciting. Two Ford cars were used. These were stripped for action until they consisted of but the chassis, with but one seat, one running board and the engine. When the cars have lined up at the goal posts with the ball directly in the center of the field, the official in charge fires a pistol and they rush at the ball in the center. From then on the elusive ball is sought, incurring upsets and all manners of accidents. The accompanying photograph shows the cars in action.

Washington Goodrich Moves—The Diamond and Goodrich tire depots, Washington, D. C., have been removed from 1319 Fourteenth street to larger quarters at 1502 Fourteenth street.

Opens Branch Office—F. M. Russell, manager of the Puyallup Garage and Pierce County agent for the Essenkay tire filler, has opened a branch office in Tacoma, Wash., at 902 Tacoma avenue.

Want Show Representation—Sixty per cent. of the Seattle, Wash., dealers have signified their intention of seeking representation at the automobile show to be held in the Armory, December 16 to 21.

Linteau Promoted—J. O. Linteau, of P. T. Legare, of Quebec City, Can., has been promoted to the managership of the Montreal branch of Legare-Gadbois Automobile Company, Ltd., succeeding M. J. Gadbois.

Philadelphia Company Moves—The American Automobile Company, Philadelphia, Pa., has removed from the southwest corner of Broad and Callowhill streets to its new sales and service building at 2116 Market street.

Syracuse Has New Garage—The Jefferson Garage Company, Syracuse, N. Y., central New York distributors for National and Hupmobile pleasure cars and the International Harvester truck, has opened a new fireproof garage.

Mineter with Rayfield—N. H. Mineter is now associated with Findeisen & Kropf Manufacturing Company, of Chicago, Ill., as factory sales manager. He will in future represent the Rayfield carbureter throughout the country.

Fire Truck for Ottawa—Ottawa, O., has just received a $5,500 automobile fire truck, which has already been demonstrated. It is 70 horsepower, and capable of making 60 miles an hour. It will carry 1,000 feet of hose and a dozen men.

Troutman Resigns—J. F. Troutman, manager of the sundry department of the Franklin Automobile Company, Syracuse, N. Y., has severed his connections with that company to take up work with the H. A. Smith Machinery Company of that city.

E. L. Retting as Wholesale Agent—A direct factory branch of the Federal Rubber Company has been opened at 361-363 Golden Gate avenue, San Francisco. E. L. Retting will act as wholesale agent and Mohring Bros. will act as retail distributors in San Francisco.

Meet Highway Commission—More than 100 members of the East St. Louis Commercial Club, St. Louis, Mo., motored to Collinsville, Ill., recently to meet the Illinois State Commission which is touring the several suggested routes for the new State Highway.

Lu Lu Club's Election—The following nominations for officers and board of governors of the Lu Lu Temple Automobile Club, Philadelphia, Pa., have been made: president, Joseph Way; vice-president, C. L. Martin; secretary, H. S. Evans; treasurer, W. C. Buck.

Retail Department Transferred—The retail selling department of the Studebaker Corporation, Philadelphia, Pa., has been transferred to the Wallace Automobile Company, which has secured new and enlarged quarters at the southwest corner of Broad and Callowhill streets.

Building Moline Garage—Fred R. Young is building a new garage on Sixth avenue, Moline, Ill., to be completed January 15. The building will be of brick, 45 feet by 150 feet in dimensions, two stories in height, to cost $20,000. The building will be known as the Plow City Garage.

Tractors for Farm Work—J. J. Dauche, a Sandusky, O., manufacturer, has organized a company to manufacture a gasoline tractor, especially adapted to farm work. It is the aim of the promoters of the concern to develop a tractor which will take the place of horses for all farm work.

Commercial Company's New Quarters—The Commercial Automobile & Supply Company, Washington, D. C., Studebaker agents, have leased the first floor and basement of the Pope building, formerly occupied by the Pope Automobile Company, and after extensive alterations will take possession about February 1, 1913.

New Orleans Show in March—This year's New Orleans La., 5-day automobile show will be held March 20-24. It has been decided by the Dealers' Association after the minority had worked hard for an earlier show. It was decided also to hold two shows each year beginning with 1913. The second show next year will be held in November and will be made an annual feature.

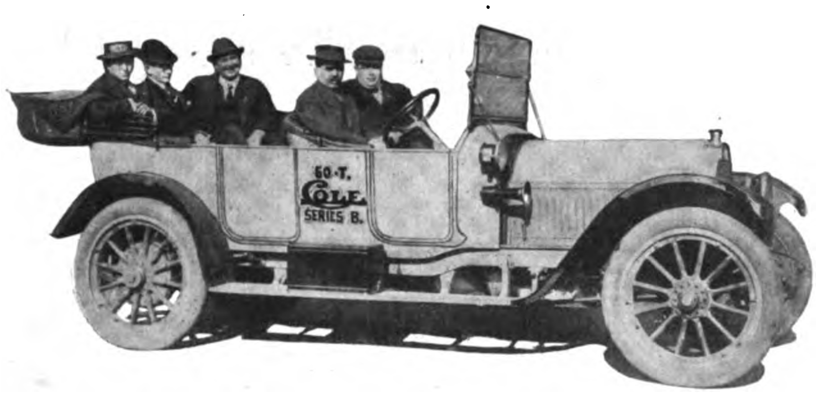
The Day School of the Boston Y. M. C. A. on a recent tour of inspection through the service department of the Packard Motor Car Company in that city



President J. J. Cole, of the Cole Motor Car Company, Indianapolis, Ind., at the wheel of the new 6-60 model

Fresno has 2,000 Cars—Fresno, Cal., has over 2,800 registered cars and the county has over 4,000.

Membership Campaign Successful—The membership campaign waged by the Vancouver, B. C., Automobile club is meeting with success.

Illinois Registration Statistics—Automobile license, issued in the state of Illinois from January 1 to September 30, inclusive, numbered 65,299.

Jacobson in Metal Field—I. M. Jacobson & Sons, Detroit, Mich., are operating a company for the sale of strictly pure metals of every description.

New York Club's Membership—The New York Motor Club, New York City, now has nearly 140 members and expects to have 200 by the time the show opens.

Wagner with Garford—H. A. Wagner has left the Peckham Motor Car Company, Dayton, O., and is now connected with the sales department of the Garford Company, Elyria, O.

Italian Imports in 1911—During the 1911 season the imports of Italian automobiles to the United States was valued at $186,746, as against $295,013 in 1910 and $674,666 in 1909.

Tri-City Traffic Resolution—Davenport, Rock Island and Moline automobile men at a meeting at Davenport, Ia., last week, unanimously adopted a resolution favoring uniform traffic ordinances for the tri-cities.

New Headquarters—Frank G. Miner, Southern California distributor of Kelly trucks has opened headquarters at South Grand avenue, Los Angeles, where the Southern Pacific coast distribution will be centralized.

Wells Changes—J. R. Wells, formerly sales manager for Legare-Gadbois Automobile, Ltd., Montreal, Que., has resigned his position to take up similar duties with the Motor Import Company, of Canada, Ltd., this city.

W. E. Bayless Appointed—W. E. Bayless, formerly Seattle manager for Fisk Rubber Company, has been appointed to succeed the late Tom Rawlins, who died several weeks ago, as manager of the San Francisco branch.

Use American Tires—Taxicabs in Norway, Sweden, Denmark and Finland will run on American tires. A contract for 750 sets of tires for use on taxis in these countries has just been closed between a Stockholm and American firm.

J. R. Thomas Appointed—J. R. Thomas, who has been manager of the Washington, D. C., branch of the United States Motor Company since March, 1910, has been made manager of the branch at Philadelphia, Pa. He has been connected with motor industries in Washington since 1905.

Anderson Resigns—D. G. Anderson, who has been cost accountant of the Russell Motor Car Company, Ltd., Toronto, Can., has resigned his position with that company to take effect at once. Mr. Anderson has been appointed the purchasing agent for the Tudhope Motor Car Company, Ltd., of Orillia, Can.

Syracuse Show in March—The Syracuse Automobile Association, Syracuse, N. Y., announces that the next show will begin Tuesday evening, March 18, and the main show will be held at the Armory. If the number of exhibitors warrants it the Alhambra will also be engaged and two shows held, as last year.

Henderson Starts Western Tour—O. B. Henderson, sales manager of the Baker Motor Vehicle Company, Cleveland, O., started the latter part of November for his annual tour through the western part of the United States for the purpose of visiting dealers, particularly those located along the Pacific coast.

Tudhope's $50,000 Building—The Tudhope Motor Car Company is putting up a $50,000 building in Vancouver, B. C. The new structure will be a combined show room, garage and machine shop. It will cover an area of 75 feet by 125 feet at the corner of Fifteenth avenue and Granville street. It will be two stories high, of concrete construction.

Atkinson Severs Connections—C. J. Atkinson, inventor and patentee of the Atkinson gas producers, has severed his connection with the Dornfeld-Kunert Company, Watertown, Wis. Mr. Atkinson's services and the use of all his patents have been secured by Fairbanks, Morse & Company, Chicago, Ill.

Centaur in Larger Quarters—The Centaur Motor Company, Chicago, Ill., distributers of the Abbott-Detroit line of automobiles, will shortly take possession of the new premises located at 2246 and 2248 Michigan avenue, Chicago, Ill. The new building has a frontage of 40 feet on Michigan avenue and extends back 170 feet, and is three stories high. It will be completely equipped.

France Buying Our Cars—In the past 10 months the value of French imports of American machines has been $340,000 in excess of the total value of the imports of the 10 months of the preceding year. At the same time, so far from losing ground on this side, French makers of automobiles de luxe have doubled their exports to America during the present year, the total up to October 31 representing a value of $800,000.

Ontario's Revenue Doubled—Ontario's revenue last year from the sale of licenses for motor vehicles totaled $50,831.25, twice the amount received during the year 1910, which was $24,394. The revenue for 1906, the first year fees were imposed, was only $15,235.15. The licenses issued last year totaled 11,339, and for 1910, 4,320, while in 1906, 1,176 licenses were issued. Fees collected for issuing charters to automobile corporations totaled $235,663.10.

Baltimore Show in February—The Baltimore, Md., show will be held this winter from February 18 to 22 inclusive. The

Automobile Incorporations

AUTOMOBILES AND PARTS

Buffalo, N. Y.—Empire Radiator Company; capital, $1,000,000; to manufacture automobile radiators. Incorporators: E. B. Green, W. S. Wicks, C. J. Ellis.

Chagrin Falls, O.—Falls Garage Company; capital, $100,000; to manufacture and deal in automobiles. Incorporators: O. S. Gore, T. O. Waite, H. D. Bishop, T. H. Huggett, A. E. Huggett.

Cleburne, Tex.—Cleburne Motor Car Manufacturing Company; capital, $10,000; to manufacture automobiles. Incorporator: H. E. Luck.

Colonial Beach, Va.—Colonial Beach Motor Company; capital, $5,000; to manufacture automobiles. Incorporators: F. W. Alexander, George Staples, H. W. B. Williams.

Chicago, Ill.—Edgar Motor Delivery; capital, $10,000; to manufacture automobiles. Incorporators: J. Edgar, E. A. Zimmerman, Abram L. Meyers.

Chicago, Ill.—Molliter Tire Company; capital, $100,000; to manufacture automobiles. Incorporators: Benjamin S. Lippincott, Bion D. Towne, William J. Higgins.

Detroit, Mich.—Kessler-Detroit Motor Car Company; capital, $10,000; to manufacture automobiles.

Findlay, O.—Northway Motor Company; capital, $600,000; to manufacture motors. Incorporator: R. F. Northway.

Indianapolis, Ind.—Tone Car Company; capital, $200,000; to manufacture automobiles. Incorporators: M. H. Miller, William P. Kirk.

Lagrange, Ga.—J. F. Carley; capital; to engage in automobile business. Incorporator: John F. Carley.

Morgantown, W. Va.—Colonial Motor Car Company; capital, $10,000; to deal in automobiles. Incorporators: A. A. Exley, W. E. Graham, J. H. Wolfe.

Newcastle, Ind.—Rose City Auto Company; capital, $10,000; to manufacture automobiles. Incorporators: F. E. Smith, C. W. Moucn, W. F. Byrket, H. M. Van Matre, G. Cameron, L. W. Bailey, A. D. Ogborn.

New York City.—American Commer Truck; capital, $10,000; to manufacture automobiles. Incorporators: R. C. Thompson, Julius Jagn, E. Thomas.

New York City.—Gilbert-Fulton Corporation; capital, $1,000; to deal in automobiles. Incorporators: G. J. Gilbert, Otto Gilbert, D. J. Fulton.

New York City.—Kell Motor-Radiator Corporation; capital, $650,000; to manufacture radiators for automobiles. Incorporators: H. A. Bingham, A. F. Garbe, C. A. Cole.

New York City.—Universal Auto Appliance and Construction Company; capital, $5,000; to manufacture motors. Incorporators: F. W. Darnstaedt, M. J. Lelerc, H. B. Tucker.

Niagara Falls, N. Y.—Niagara Motor Car Corporation; capital, $10,000; to manufacture automobiles. Incorporators: C. E. Cromley, D. M. Hepburn, L. S. Hepburn.

Richwooe, O.—Scharf Gearless Motor Car Company; capital, $5,000; to manufacture and deal in automobiles. Incorporators: G. W. Worden, J. A. Scharf, W. H. Siples, H. E. Payne, L. J. McCoy.

St. John, N. B.—Maritime Motor Car Company; capital, $250,000; to manufacture automobiles.

South Bend, Ind.—South Bend Motor Car Works; capital, $10,000; to manufacture automobile parts. Incorporators: J. D. J. Farneman, A. C. Mecklenburg, Hilton Hammond.

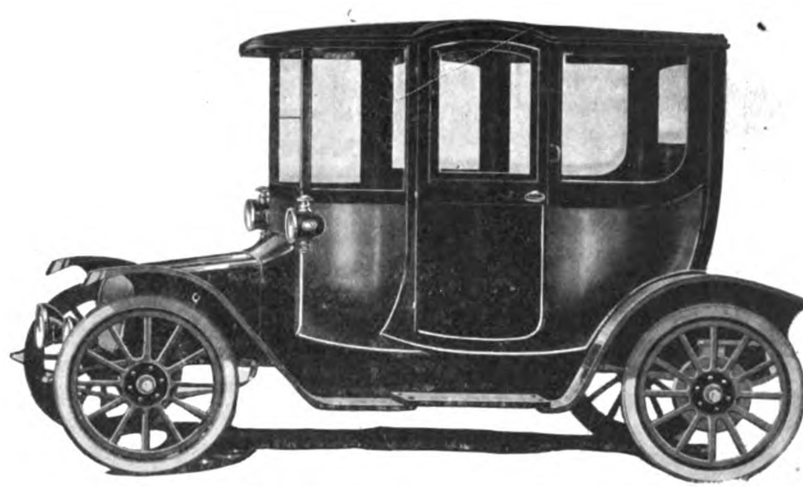
show will be combined, the pleasure and commercial cars to be shown at the same time. The show will be under the auspices of the Automobile Club of Maryland and the Baltimore Automobile Dealers' Association as heretofore. Application has been made by the joint committee of these two organizations for the use again of the Fifth Regiment Armory.

St. Paul's Ambulance—The city hospital, St. Paul, Minn., has ordered a Studebaker 30 emergency ambulance. The chassis is a stock model.

Hood Sales Manager—Wallace Hood has been appointed sales manager with supervision of advertising of the Westcott Motor Car Company, Richmond, Ind.

Davis Resigns—G. M. Davis, advertising manager of the Pierce Arrow Motor Car Company, Buffalo, N. Y., has resigned and will engage in newspaper work.

Sullivan Alco Manager—G. L. Sullivan has been appointed manager of the Chicago, Ill., branch of the American Locomotive Company, succeeding B. C. Day, resigned.



New model with forward drive, manufactured by the Chicago Electric Car Company

Alco in San Diego—The Los Angeles Alco Motor Sales Company, Los Angeles, Cal., southern California agents for Alco cars and trucks, has established a branch in San Diego, Cal.

Fort Dodge Show Plans—The second annual northern Iowa automobile show under the auspices of the Fort Dodge Dealers' Association is to be held at the Armory February 26 to March 1.

Brooks with Coach Builders—Emerson Brooks has purchased an interest in Burr & Company, coach builders, in New York City, and will devote his energy to the sales and repair departments.

Remy's Minneapolis Branch—The Remy Electric Company will open a branch in Minneapolis, Minn., January 1 and Gerald Fitzgerald, assistant manager at Chicago, Ill., is to be made manager.

Electric Starter for Henderson—In addition to the wire wheel equipment of the Riley type with which the Henderson company is going to fit its cars in the spring, an electric starter will be a part of the equipment.

Republic Rubber's New Home—The Republic Rubber Company, Minneapolis, Minn., will have a home in the new Murphy automobile building at Thirteenth street and Hennepin avenue, which is now constructed as far as the street level.

Milwaukee's Good Roads—More than 350,000 tons of asphalt were laid on the streets of Milwaukee, Wis., during the season of 1912, according to the report of the commissioner of public works, and next year it is planned to increase this by 50 per cent.

Milwaukee Automobile Stealing—The theft of five cars in Milwaukee, Wis., in eight days has caused a renewal of the agitation for a state law which will place automobile stealing on the same plane as horse stealing.

Contemplates Fire Truck Purchase—The Delaware Fire Company, Wilmington, Del., one of the fire companies contracting with that city annually for fire service, contemplates the purchase of a motor fire truck and has appointed a committee to look into the merits of the different makes.

Chauffeurs Receive Increase—Chauffeurs in the St. Paul, Minn., fire department have received an increase in their pay from $85 to $100 and the assistants will receive $85. The positions of drivers of motor apparatus will be open to competent men outside as well as inside the department.

Coffin in Southern Run—H. E. Coffin, vice-president of the Hudson Motor Car Company, Detroit, Mich., was one of the participants in the Thanksgiving run of the Savannah Automobile Club to the Lawyers' Club in Liberty County. Thirty-five cars participated in the run. The purpose of the run was to boost the good roads movement over the counties traversed.

Should Have Been Phosphor—A typographical error caused the word sulphur to be substituted for phosphor in the brief outline of the paper on Copper Alloys for Motor Car Service read by W. H. Barr before the Detroit section of the S. A. E. as given in THE AUTOMOBILE for November 14. It is obvious that sulphur does not have a beneficial effect on bronze as stated.

Des Moines Show in March—The fourth annual show of the Des Moines Automobile Dealers Association, Des Moines, Iowa, will be a two weeks' exhibition, the first week being devoted to pleasure cars and the second to commercial cars. March 3 to 8 will be given over to the pleasure cars. This will be the first time that a complete commercial show has been attempted in Iowa.

Three Wheel Electric Truck—To take the place of a number of two-horse tip carts which it operates, the Third Avenue Railway Company, New York City, has developed a novel type of electric truck. This has but three road wheels, the single one in the front having an electric motor contained within it. The large steel-tired rear wheels and body of the horse tip cart are retained and a heavy frame from which the batteries are suspended and a steering gear complete the new truck. It can be turned around in its own length.

Automobile Incorporations

GARAGES AND ACCESSORIES

AMSTERDAM, N. Y.—J. E. Larrabee Company; capital, $100.000; to deal in all kinds of automobiles and supplies. Incorporators: L. L. Larrabee, W. W. Leavenworth, K. L. Larrabee.

BUFFALO, N. Y.—American Kushion Kore Tire Company; capital, $10,000. Incorporators: K. E. Wilhelm, C. M. Baldy, C. H. Tavlor.

BUFFALO, N. Y.—Buffalo and Interurban Motor Delivery Company; capital, $125,000; to carry on a general automobile delivery. Incorporators: J. G. Berner, C. T. Horton, W. D. Grandison.

EVANSTON, ILL.—Penn. Oil Company; capital, $2,500; dealing in oil and supplies. Incorporators: J. M. Maddle, L. Ladole, L. B. Davis.

GREENSBORO, N. C.—Reitzel Auto Service Company; capital, $25,000; to carry on garage. Incorporators: J. H. Reitzel, O. C. Klingman, L. G. Klingman.

INDIANAPOLIS, IND.—Miller Carbureter Comnany; capital, $200,000; to manufacture carbureters. Incorporators: F. C. Fairbanks, R. M. Fairbanks, L. H. Colvin, O. L. Snyder, N. M. Doyle.

KENTVILLE, N. S.—Provincial Motor Car Company; capital, $50,000; to carry on a garage business. Incorporators: R. E. Harris, J. J. Porter, G. N. Reagh, R. J. Shaffner.

NATCHITOCHES, LA.—Natchitoches Livery & Garage Company; capital, $10,000. Incorporators: M. Aaron, J. B. Presburgm.

NEW YORK CITY.—Bradhurst Garage Company; capital, $5,000; to carry on a general garage business. Incorporators: J. C. Jackson, P. R. Gorden.

NEW YORK CITY.—Foreign & Domestic Automobile Repair Company; capital, $10,000; to repair automobiles. Incorporators: L. O. Rothschild, Otto A. Deffan, Max Kaplan.

NEW YORK CITY.—Motor Hauling Corporation; capital, $5,000; to do automobile trucking. Incorporators: W. G. McGrath, M. B. Sentner, S. B. Kerr.

NEW YORK CITY.—Rector Engine Corporation; capital, $150,000; to manufacture motors. Incorporators: Edward Gore, William Magowan, S. C. Yeaton.

PHILADELPHIA, PA.—Auto Safety Signal Lamp Company; capital, $100,000; to manufacture a safety signal device. Incorporators: L. Abeles, J. J. Drew, J. G. Gray.

QUEENS, N. Y.—Elmhurst Garage; capital, $5,000; to carry on a garage business. Incorporators: T. G. Smith, P. J. Testan, Millie Testan.

ST. PETERSBURG, FLA.—Ramm's Garage; capital, $100,000; to engage in garage business. Incorporator: F. W. Ramm.

WASHINGTON, D. C.—J. B. Bayne; capital, $4,000; to engage in garage business. Incorporator: Clarke Waggaman.

CHANGES OF NAME

AKRON, O.—Ideal Commercial Car Company; change of name to the Akron Motor Car & Truck Company.

ST. PAUL, MINN.—Electric Manufacturing Company; increase of capital to $50,000.

ST. LOUIS, MO.—Meuhling Motor Car Company; capital, $15,000; to conduct an automobile repair plant.

McCormick Power Spark Plug; Ackerman Two-Pane Windshield; American Auxiliary Air Valve; Gray & Davis Starter for National Cars; Emergency Fuel Tank Gauge; Triplex Gas Saver

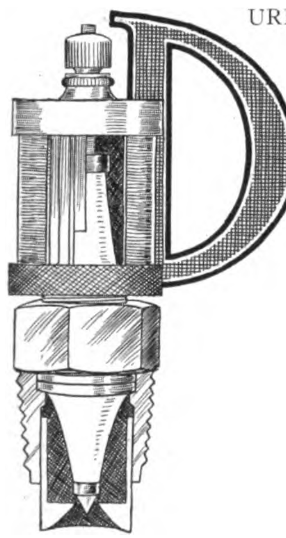

Fig. 1—McCormick power spark-plug

DURING the past year many developments have been made in spark-plug design and construction. One of the plugs involving a number of novel ideas is the McCormick power spark-plug, Fig. 1, which is distinguished by the use of a porcelain, the lower part of which is shaped as a cone and contained in a chamber serving as primary ignition space, of an electrode construction which produces a spark traveling around the positive sparking point and a condenser inclosed in a steel-case and effecting a stronger spark than would be obtained without its use. The illustration shows these several features, part of the shell and the steel-case being cut away for this purpose. The principal part which distinguishes this plug from others is the condenser which is interposed between the binding post terminal and the firing point. The latter, shaped as shown in Fig. 1, is covered by the porcelain insulation, against the lower end of which seats the flat flange of the conical point. This point is located centrally within the ring-shaped negative electrode, consisting of a sleeve which fits into the inner face of the shell. The spark always occurring at the coolest points is formed alternately at various places around the circumference of the shell, so that it travels, so to speak, around the positive electrode and does not permit the formation of soot and oil deposits on the plug. The effect of the space above the sparking point is that mixture is compressed in it during the compression stroke, and is ignited quickly all over. It is claimed that by the combined effect of the various features of this plug its working efficiency is materially increased, resulting in the production of a very powerful spark, which again helps to produce perfect combustion. The plug is made by the McCormick Manufacturing Company, Dayton, O., in the standard sizes, so that it may be fitted in place of any other spark-plug which it is desired to replace in an automobile motor. All McCormick spark-plugs are made standard and with interchangeable parts.

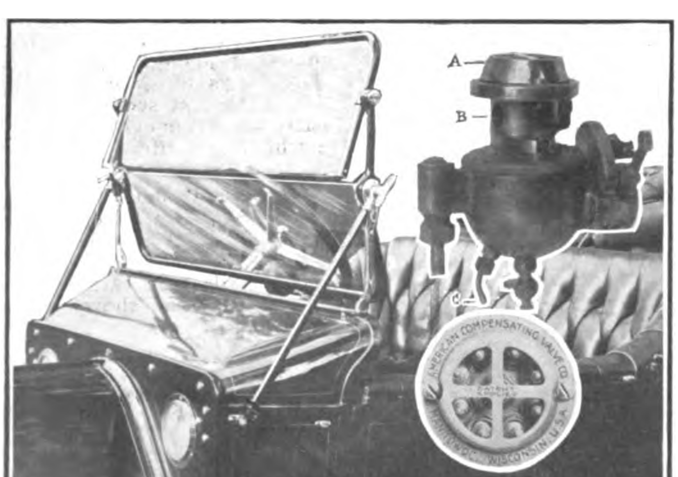

Fig. 2—Ackerman windshield. Fig. 3—American compensating valve

Matchless Pocket Lighting Device

The pocket lighter, Fig. 7, called the Matchless, is made by the Schiller Manufacturing Company, Chicago, Ill., for the lighting of acetylene and oil lamps on automobiles without the use of matches. The lighter is hardly 5 inches long and fitted with a clip so that it may be carried in the pocket like a fountain pen. It consists of a long, hollow piece into which fits a cap carrying a steel rod which has an alloy-steel point. The latter is surrounded by a wick. In practice the long piece is filled to about half its capacity with gasoline or alcohol, so that the wick is always soaked with the fuel. To produce a flame the cap and rod are pulled out of the hollow piece and the end of the rod is struck against the knurled piece of steel attached to the long piece, whereby a series of sparks is made which ignite the alcohol or gasoline with which the wick is soaked. A small but strong flame is thus obtained which is not easily extinguished by wind.

Emergency Gasoline Tank Gauge

The gasoline gauge shown in Fig. 6 is made by the Emergency Novelty Company, Port Huron, Mich., and is equally adaptable for gravity and pressure-feed systems. The gauge is attached and connected to the tank C by means of a coupling F inserted into the gasoline line leading to the carbureter and a pipe G providing a communication between the upper portion of the tank and the upper space in the gauge vessel. The latter is a glass tube, the upper and lower end of which is closed by a check valve opening downwardly. B is the lower valve which separates the gasoline in the tank from that in the gauge, and A is a pushbutton which may be pressed down. If this is done, the air pressures in gauge and tank equalize through the pipe G, and the gasoline in the gauge assumes the same level as in the tank, so that the amount of fuel contained in the latter may be read easily on the scale attached to the gauge glass. If the glass is broken, only the gasoline in the gauge tube is spilled, while the contents of the tanks is kept from flowing out by the valve B, which is pressed against its seat formed at the bottom of the gauge, by a spring. The gauge scale may, of course, be adapted to fit any type or design of gasoline tank, making the gauge applicable to any automobile.

Edelmann Tire Chuck and Gauge

E. Edelmann & Company, 229 West Illinois street, Chicago, Ill., have added another tire specialty to their line of accessories. This is the inflating chuck, Fig. 6, which is an entirely automatic device. It is simply a coupling built up on a right-angled air lead, one arm being formed with a ratchet surface over which the hose is slipped while the other fits over the tire valve, being pressed on it to make an airtight joint. When the tire is fully inflated, the air chuck is pulled off the valve, which is thereby shut automatically. Fitted in the chuck is a tire gauge of the ordinary Edelmann design, which at all times indicates the pressure obtaining in the tube.

American Compensating Valve

A sensitive compensating valve for multi-cylinder engines is seen in Fig. 3; it is said to give more perfect combustion at high speeds than can be obtained without it. The valve consists of a truncated cone in which a number of spring-controlled check valves are mounted and which is attached to the air inlet of the carbureter. Fig. 3 shows the valve mounted on the air inlet of a Schebler carbureter. The valve is shown at A, being mounted in place of a plate which normally closes the pipe, which is bored at B for the normal air admission. The air opening B is fixed and supplies the motor at low speeds, wherefore the needle valve C must be adjusted to give the right mixture under these conditions. As the motor speeds up with the throttle opened wider, the auxiliary compensating valve supplies the necessary air, one check valve opening first, the others after, in response to the increasing vacuum in the cylinders. The design of compensating valves varies for the various types of carbureters, but the American Compensating Valve Company, Manitowoc, Wis., makes designs to fit every type of carbureter now on the American market.

Ackerman Ventilating Windshield

Joseph N. Smith & Company, Detroit, Mich., manufacture a two-piece type of windshield which permits of a variety of positions of its panes and consequently gives a variable effect. Fig. 2 shows the shield in such a position that the upper shield deflects the wind so that it passes over the head of the driver, while the lower pane, being turned in, ventilates the lower space in front of him. The upper pane may be turned completely around the axis formed by the two points at which it is secured to the frame of the lower pane. The joints are so constructed as to be proof against rattling. The shields may be had with black enamel, brass or nickel finish, or a black enameled frame with brass or nickel mounting.

Bremer-Wilson Gasoline Saver

Under the name Triplex Gas Saver, the Bremer-Wilson Manufacturing Company, 1256 Michigan avenue, Chicago, Ill., sells a small and effective device which is designed for the breaking up of liquid fuel globules getting past the throttle. To obtain perfect atomization of the fuel, the mixture is forced, on its way from the carbureter to the motor, through a fine, triple screen of wire gauze which is held in a brass frame shaped as the device in Fig. 8. A part of the brass frame on each side is formed en relief, so as to fit between the carbureter and manifold flanges, to which it is bolted. The opening in the gas saver is equal in diameter to the size of the carbureter; the thickness of the device is about .5 inch, so that the only difference made by the installation of the saver on the engine is that the carbureter is placed so much lower, as compared with its original position. The trouble of installing the device is very small, and the result of better atomization of the fuel inevitable.

National Car's Self-Starter

The Gray & Davis starter used on the cars of the National Motor Vehicle Company, Indianapolis, Ind., operates in conjunction with the lighting generator, the latter being of the constant-speed type. This generator construction is used to obtain a current output at constant voltage, a slipping clutch being used between the driving member and the generator shaft itself. The current is fed to the battery which floats on the line of the lamps. The motor which serves for starting is actuated by the current from the battery; it is so connected to the engine that the pressure on a pedal both closes the circuit which energizes the field of the motor and throws the motor shaft in gear with the crankshaft. As soon as the engine speeds up sufficiently, the starting motor is automatically thrown out of gear with the

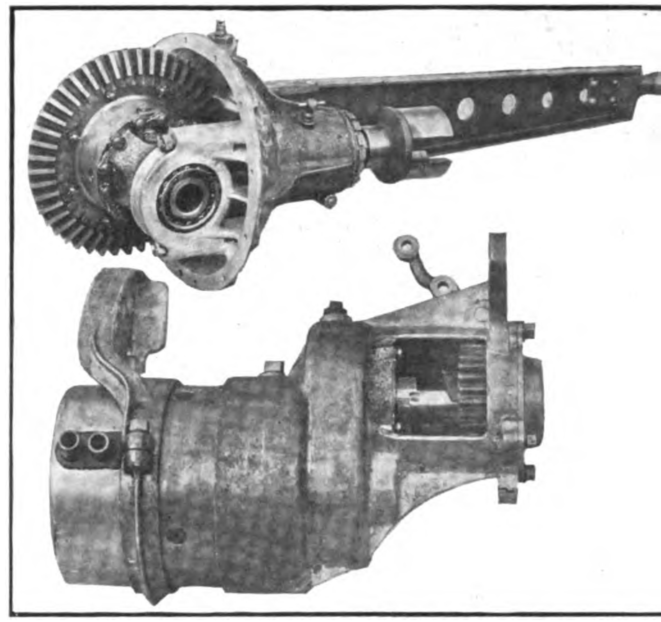

Fig. 4—Gray & Davis electric starter of National automobiles

engine, and the circuit is interrupted, whereupon the dynamo generator begins to recharge the battery. The battery used in the National equipment is of sufficient capacity to furnish current for the lights for several hours.

Wolf Automobile Fuel Mixer

The mixer of A. M. Wolf, 146 East Eighty-first street, New York, is a device of one-piece construction which fits between the carbureter and the intake pipe. It consists, in principle, of an open sheet-metal cylinder, the lower end of which carries a horizontal flange, and the wall of which has been cut along its entire height, at two places diametrically opposite to each other. Two of the four edges thereby produced are bent inwardly under an incline of about 50 degrees, thereby forming two inclined surfaces in the mixture passage, which have an effect somewhat akin to that of a screw, resulting in a whirling motion set up in the mixture traveling toward the inlet manifold. This whirling motion, in turn, brings the particles of the mixture in very intimate contact and causes whatever liquid parts are carried along in it to be broken up and thus prepared for efficient combustion.

Lubro Anti-Freezing Compound

The Lubro Oil Company, Cleveland, O., has manufactured an anti-freezing fluid, which is red in color, harmless in action and is claimed to prevent the radiator water from freezing even in the coldest weather. In practice 1 volume of Lubro is used to 2.5 volumes of water.

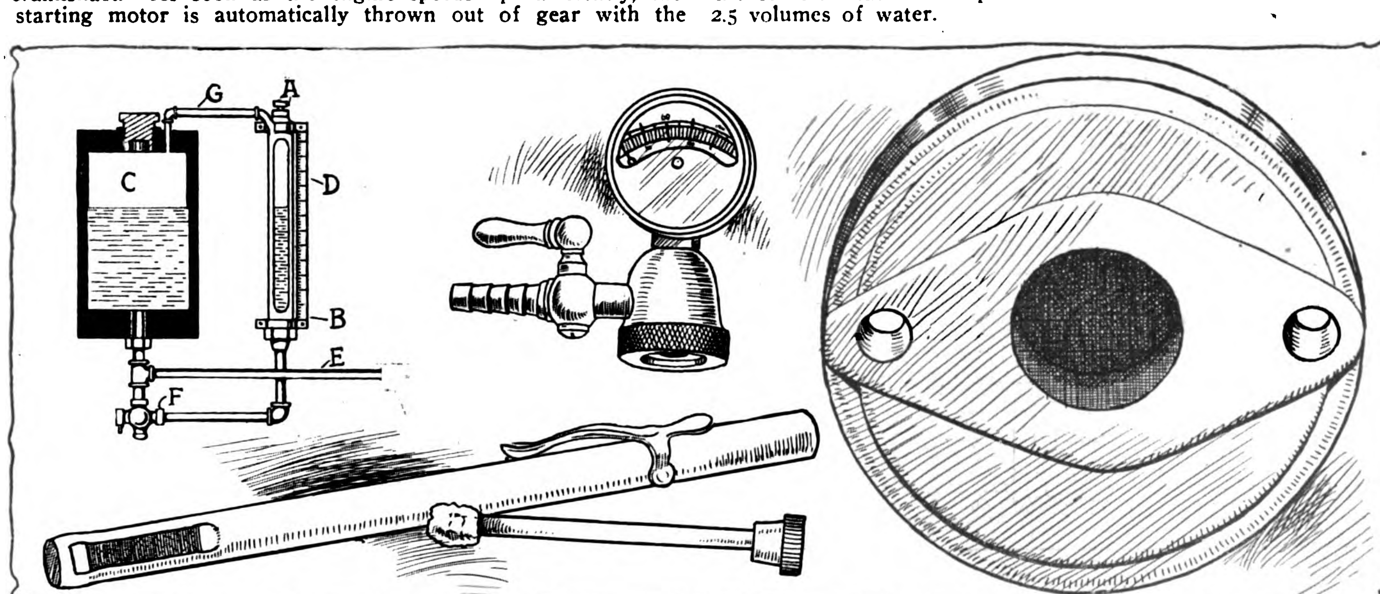

Fig. 5—Emergency fuel gauge. Fig. 6—Edelmann inflation chuck. Fig. 7—Matchless pocket lighter. Fig. 8—Triplex gas saver

AUTOMOBILE Engine Carbureter—In which the walls of the mixture chamber are contractible for the purpose of throttling.

This patent refers to a carbureter, Fig. 1, the body of which is formed with parallel sides and has at its upper end a discharge port M for mixture. Into this body a pair of opposed, inwardly curved, plates P are fitted, being hinged at their lower ends H and forming a flanged port just below M. Between the inwardly curved portions of plates P, a fuel jet is provided which communicates with a float-chamber regulating the supply of fuel. The plates P form a mixing chamber above the jet and an air chamber below it, these chambers being adjustable, due to the movability of the plates P. An air valve for regulating the amount of air admitted into the carbureter is provided by two plates Q depending downwardly from the lower ends of P. A mechanism A permits of simultaneously actuating the plates P and Q, thereby regulating the amount of air admitted to the carbureter and maintaining a fixed ratio between capacities of the throttle and the air inlet.

No. 1,045,613—to Harris C. Roth, Chicago, Ill. Granted November 26, 1912; filed July 29, 1911.

Rotary Valve Design—A sleeve which is positioned between the cylinder wall and the head.

The valve design which is the subject matter of this patent, is shown in Fig. 2. This figure shows a cylinder C which is formed with a concentric head H secured in the top end of C and made with a somewhat lesser diameter. Thereby an annular cavity between the cylinder and the head is formed in which a sleeve valve V is in place. The ports are formed on one side of each cylinder and the manifolds are so constructed that one inlet pipe serves the twin inlet ports P of two adjacent cylinders, while the outlet ports Q are served by separate manifold leads. By means of gearing G the sleeve valves are operated at suitable speeds through the movement of the cylinder pistons.

No. 1,045,500—to Edward H. Belden, assignor to Belden Engineering Company, Pittsburgh, Pa. Granted November 26, 1912; filed December 26, 1911.

Autogenous Welding Torch—Comprising separate inlet conduits for oxygen and a fuel gas, and a capillary connection between them.

The welding torch referred to in this patent consists of a head H, Fig. 4, which is made of one integral block of heat-resisting material and formed with conduits C1 and C2, for a combustible gas and for oxygen respectively. The conduits into the head are separate; C1 opens directly into a passage forming an orifice O in the removable tip T of the torch, while C2 communicates through the bore B with that passage. The bore B intersects C1 at a practically right angle, so that the gases meet before entering the tip.

No. 1,045,506—to Worthy C. Buckham, assignor to Davis-Bournonville Company, New York City. Granted, November 26, 1912; filed February 27, 1912.

Automobile Motor Lubrication—Being a connection between crank and flywheel chamber.

This patent relates to a lubricating scheme, Fig. 5, which comprises a flywheel F housed in an annular enlargement E of the crankcase C. In the lower portion of E is an oil chamber O in which part of the flywheel is immersed: an oil-receiving pocket P1 is formed adjacent the top of E, while the lower portion of it has a transparent panel P. Centrifugal action sends oil into P1, whence it returns to C.

No. 1,045,772—to Howard E. Coffin, Detroit, Mich. Granted November 25, 1912; filed April 13, 1908.

Automobile Muffler—Combining the action of tortuous passages and baffling plates.

The muffler described in this patent comprises a casing C having a head H formed with a flange F. An inlet pipe I closed at the outer end by a perforated plate supplies the interior of the muffler with exhaust gases. The latter pass out of the pipe through other perforations therein, formed close to the cap C which closes its inner end. Baffle plates B mounted on rods R, which hold the muffler together, offer further resistance to the gases, which leave through the funicular discharge D.

No. 1,045,614—to John H. Sames, Galion, O. Granted. November 26, 1912; filed April 16, 1912.

Electric Automobile Signal—Comprising a diaphragm and a vibrating armature.

This patent relates to an electric horn construction which includes a hollow body to the front wall of which a resonator is attached communicating with the interior of the body portion. To the latter a diaphragm is removably attached and it forms a chamber between it and the front wall of the body portion above mentioned. Electro-magnets are secured adjustably to the body portion, being out of contact with the vibrating portion of the diaphragm. An insulating disk is supported by the magnets and an arm mounted on the disk, as well as an armature resiliently secured to it. This armature is so constructed that when the current is closed it makes intermittent contact with the arm mentioned above.

No. 1,045,706—to Martin E. Hepburn, Elgin, Ill. Granted November 26, 1912; filed October 26, 1911.

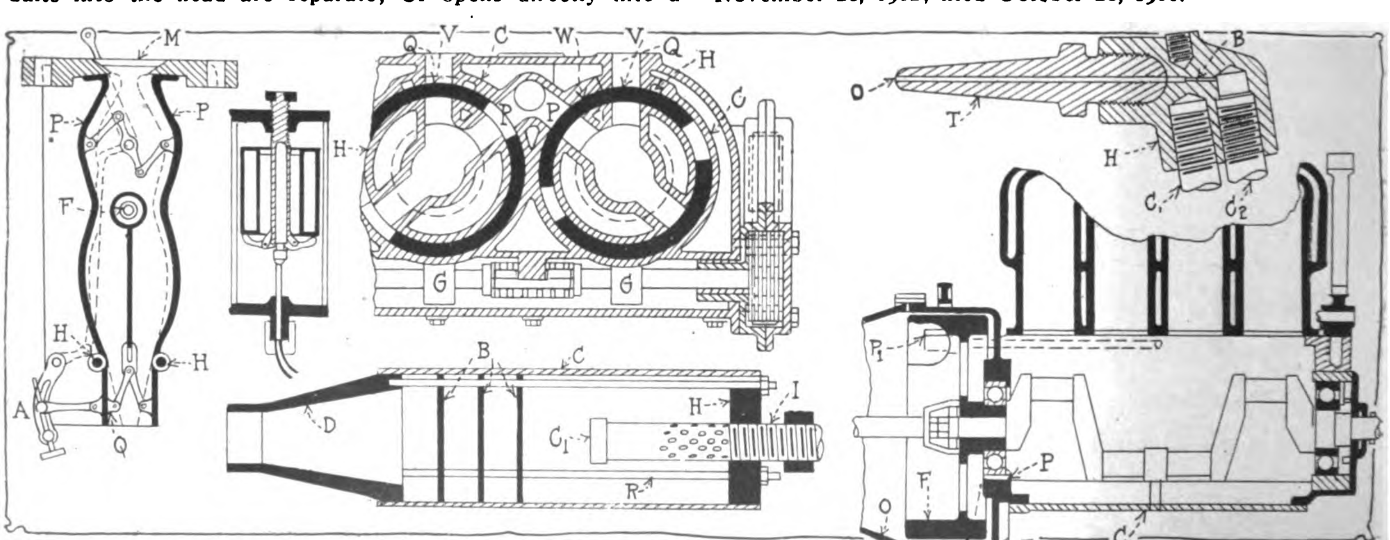

Fig. 1—Roth carbureter. Fig. 2—Belden rotary valve. Fig. 3—Sames muffler. Fig. 4—Buckham welding torch. Fig. 5—Coffin oiling system

VOL. XXVII NEW YORK—THURSDAY, DECEMBER 12, 1912—CHICAGO NO. 24

The AUTOMOBILE

One Reason Why Cars Are Stored In Winter

Radiators Freeze In Open Sheds While Hotel Guests Are Entertained

Style of open shed common to the average inn; a relic of the horse

IT is with regret that the red-blooded motorist who takes a keen delight in speeding through the frosty air of a winter evening, puts away his car until a milder climatic condition shall have again returned. Every winter brings an increase in the numbers of those who have joined the ranks of the all-year-round motorists who, either for business or pleasure, are to be found on the roads throughout the country during the time the snowstorm and icy wind have come into their own and rule supreme.

Around the large cities throughout the United States there are a large number of inns or hotels which cater to the passing automobilist. Many of these are open all winter and every year finds more who find the cold-weather trade profitable. In a great many respects these inns are similar to those which were famous in the old countries of Europe before railroad travel became common. These were open all year and the passing traveler could stop at any time and secure accommodations.

Travel on the highways is coming back. In place of the old stage coach and the mounted traveler, the automobile, speedy as the railroad and more comfortable with its luxurious inclosed winter body, is found everywhere, at any season, going from town to town. The inns and taverns along the roads connecting business centers are beginning to cater to trade of this kind, and

A—Shed behind one of the most popular inns in the vicinity of New York. Large sign in foreground pointing to this alleged garage to indicate to guests where cars should be stored while at the inn. Shed used also as chicken-coop and storehouse

B—Large stone garage in connection with one of the largest hotels just outside of New York City limits. This is one of the few garages connected with a hotel which furnishes adequate shelter and protection against cold

yet they overlook one of the most important of all points, the accommodation for the car.

In order to look into the conditions which face the automobilist who braves the cold to make either a short or long trip, a run was taken starting from New York and following along one of the main lines to Boston for a considerable distance. This is one of the most traveled routes in the East, and the inns along this line receive more patronage during the winter than can be found in most other districts. There are a number of large towns along the way which handle a large part of the accommodations for long distance touring parties for the simple reason that the accommodations at the smaller inns are not what they should be for the car, while for the parties themselves they are all that could be desired. Frequently it is not convenient to make one of the larger towns for dinner or even for the night. A conversation with the proprietor never fails to disclose his expectation of a great increase of winter trade this season, and he invariably based his observations on the fact that his patrons had told him that they intended to keep their cars going all winter.

When asked where the parties who visited the inn left their cars, the replies were various, but always interesting. One, after making wary inquiries regarding the purpose of his visitor, stated that he was just about to have a charging station for electrics installed, and that his sheds were not in very good condition at the time, although they would soon be in excellent shape, so people left the cars outside in a small parking place, but a walk around to the back disclosed a large and ornate red sign with GARAGE, spelled out in big gold letters and a hand pointing to an open barn-like structure that serves as a combination woodshed, storehouse and hen coop. It is depicted at the top of this page, along with its identifying and somewhat necessary sign. A further conversation with the proprietor who dwelt at length on the comforts and delights of his house, developed the fact that, although nine-tenths of his guests arrived by automobile, he had never thought of providing a protected spot for the car in which they arrived, regardless of the weather.

While some of the large hotels are provided with stone garages containing a stove, these are among the minority. In illustration B is shown one of the stone variety lying along one of the Boston routes. This is connected with an exceptionally large hotel and is everything to be desired in its arrangement. Contrast with this, however, the condition shown in the illustration C, where one of the largest inns along the route from New York to Albany may be partially seen. There is not even a shed in this instance. A sudden rain or snowstorm would find the cars unprotected and open to the damage which may result. Within the inn, however, the appointments are most luxurious. Nothing has been omitted in the arrangement of the furniture or decorations which would lead to the attractiveness of the surroundings. Yet the accommodations for the costly and richly upholstered cars which frequent this resort are worse than those found even at some of the smallest taverns.

On the grounds connected with another prominent inn along the Albany line may be found the sheds depicted at D. This shed, like many of the others, is a relic of the old horse days. The halter ropes are still hanging in the stalls and the feed boxes are along the walls. It is no doubt a protected spot in many ways, but on a cold winter night would furnish little security and no assurance against a frozen radiator.

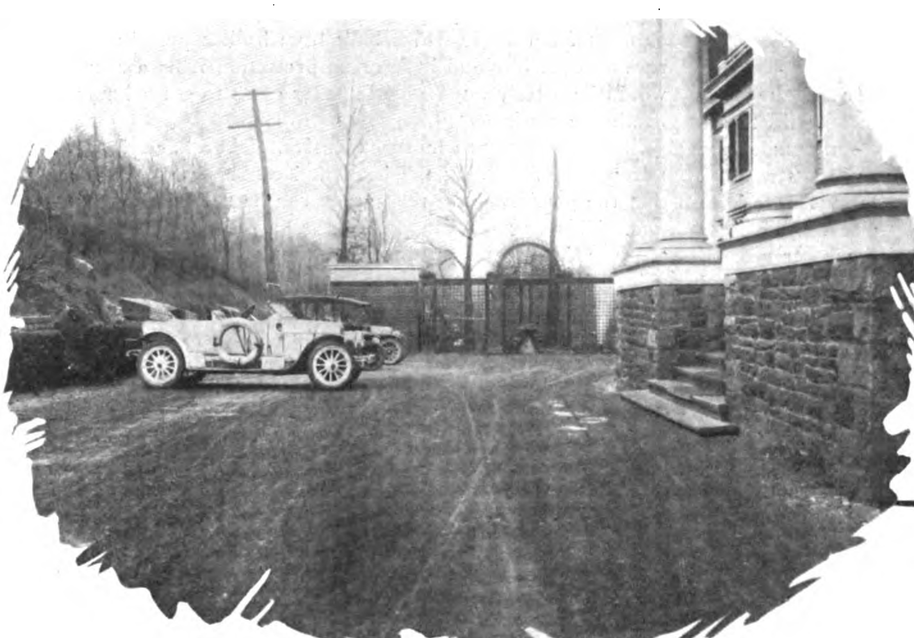
When the proprietor of one of the large inns was asked how the guests' cars were protected against the cold, he stated that little trouble was experienced in that direction as he employed a man whose duty it was to go up and down the line of cars located in the sheds and turn over the motors. What would happen in a case of one of our latest models without a starting crank, he did not state. It is safe to say, however, that the idea of the stable boy turning over the motor with an expensive electric starter would not appeal to the average owner.

One innkeeper along the Boston route has converted a stone stable into a garage. He uses one corner for his laundry, and the heat of the stove used in this corner is sufficient to maintain a steady heat through the garage. He further declares that as far as he knows he is the only proprietor within a distance of several miles along that particular route who maintains such a garage. He has sufficient room to store several cars, and this fact alone has brought him considerable trade showing that the desires of tourists are in this direction. Indeed, the idea of heating his garage was given to him by the remarks of guests of his inn. This garage is shown on page 1203.

An excellent idea which has been adopted by one man who has realized the value of maintaining a heated inclosure for the cars of his guests shown at the bottom of page 1202. One portion has been separated from the rest by a thick partition. The front is inclosed by rolling doors. The track for each one of these doors runs along the entire length of the closed portion thereby enabling anyone to reach any car without disturbing or moving any other. That is to say, any portion of the front of the inclosed portion can be opened for the entrance or exit of a car. At the other end of the shed, the central portion of which is left open, is a room which serves as a stockroom for gasoline, tires and a few tools. A telephone is located in this room also, so that it would be possible in case of a breakdown to reach the town nearby by telephone, secure necessary parts and make repairs while the party waited within the hotel. This shed was formerly opened for its entire length, but is now arranged as shown and described, with very little sacrifice of space. The inclosed portion can be locked and in the summertime can be thrown open or used as a storehouse.

While at this time of the year the chances of the radiator freezing during the day are still remote, at the same time it is very difficult to start many cars while the motors are as cold as they become while standing in an exposed spot. At night the danger of freezing radiators is exceedingly great as the temperature changes which then occur are sudden and often radical. The results are so costly to the owner, who may possibly have to purchase a new set of cylinders and a new radiator, that the precautions which should be observed are justified. The device of employing a man to walk up and down in front of the line of cars in a shed turning over the motors by hand will not suffice. In fact, in very cold weather it will not even keep the water from freezing. Blankets over the radiator and hood, while very good to stave off the effects of a frigid atmosphere temporarily, are not satisfactory when the car is to be left standing for any length of time. Non-freezing solutions, while effective, are very often forgotten or are not put in because the owner perhaps had no intention of stopping when he left his home. To drain the radiator every time the car is stopped for an hour or so is too much trouble, and should be unnecessary.

A heated garage is not necessarily a great expense. It is not imperative to have the temperature much higher than



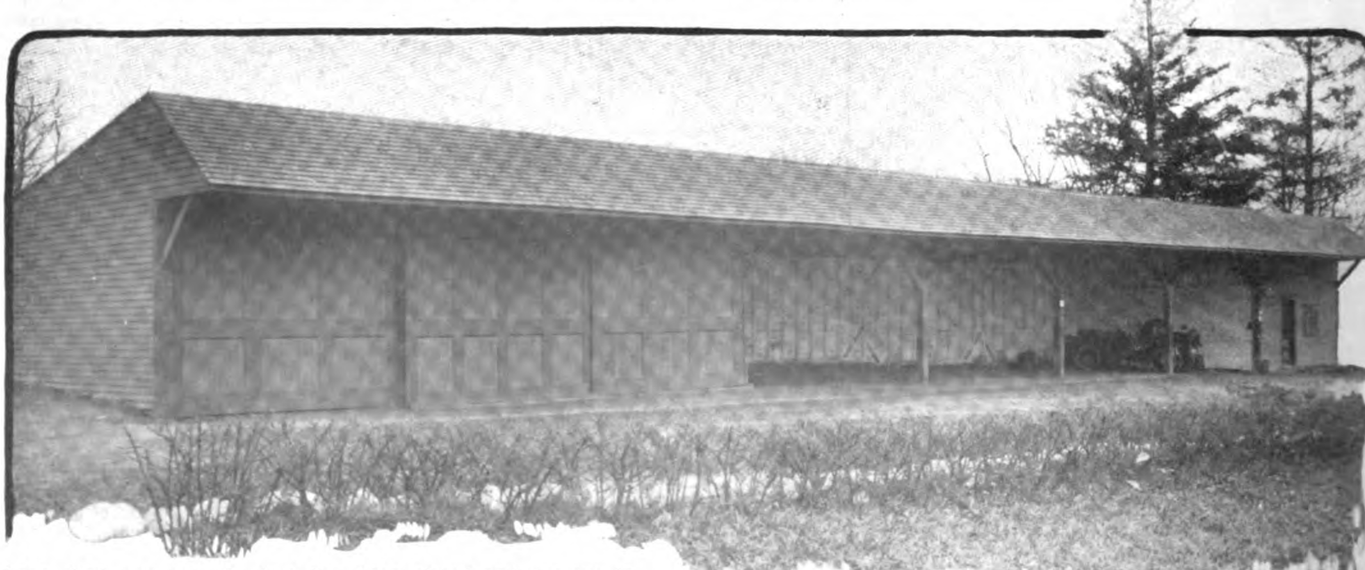
C—Showing a portion of the pretentious entrance to one of the large inns along the line between New York and Albany, which does not even provide a shelter against a sudden rain. Cars are left standing as shown, in parking space

D—Squalid, tumble-down shed which is pointed out by a well-known innkeeper as a spot where guests may leave their cars in case it rains; otherwise, cars are left in a parking space on lawn. This inn stays open all winter long

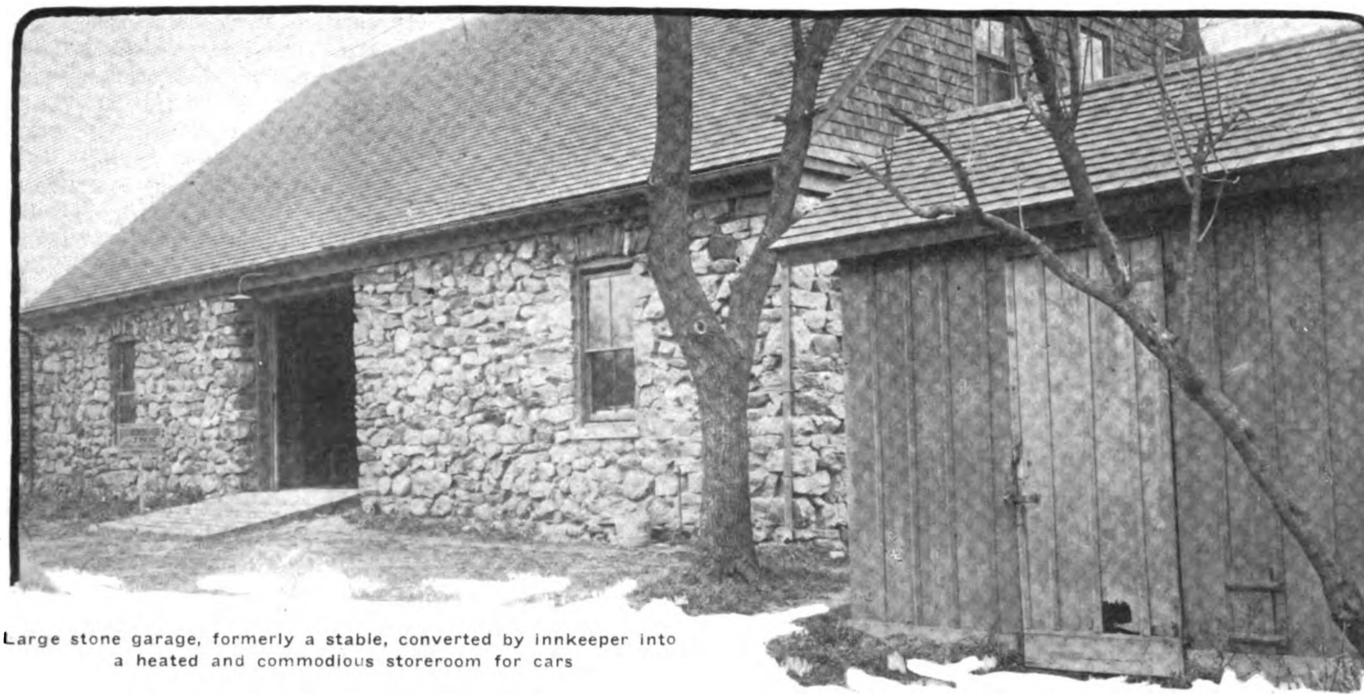
Another view of stone garage used in connection with a large hotel just outside of New York City

50 degrees. Above this temperature most cars will start easily, and there is no danger of freezing. The number of cars visiting an inn are not often great at any one time. Hence, there will be no necessity for providing extraordinarily commodious quarters for any large number of cars. A small section of the shed heated in the manner described above, by the use of a light partition would not be expensive, and would more than compensate the proprietor of the garage who arranged such a structure. Nearly all the inns which have widespread reputations have been standing since the time of the horse days or else they are the outgrowth of the bicycle roadhouse. Many of the latter type of hostelry have been very much enlarged and reconstructed throughout. All of these had sheds which accommodated horses and also a bicycle rack. There was little or no bicycle riding after the late fall season and the horse was capable of withstanding severe cold if left with a blanket thrown over him. When reconstructing the inn for the automobile and its party, the sheds were left exactly as they were. They have not grown in the majority of cases with the inn. Automobiles are parked about lawns and along the sides of the hotel approaches, while wood piles to provide fuel for the cheerful log fires which are the pride of many hostelries occupy the sheds. Many of the sheds have the ground beneath them full of glass from broken bottles or nails from boxes which have been broken up. In others, the roofs are leaking and little or no protection from a rain, while it would be utterly impossible in other cases to get a limousine beneath the roof.

Stone garages are more expensive. They have, however, the advantage of holding the heat, and can be built in such a way that the portion above the garage can be used as servants' quarters. This was done in one of the garages illustrated. As may be seen in the illustration, the upper part of the garage is shingled and provides a warm and cosy residence. This makes an ideal combination, although it is somewhat expensive to build. The heat that takes care of the servants' quarters can then be utilized to take care of the entire building, garage included. The laundry and other accessories of the hotel can be housed within such a building which could be built with a basement without any difficulty. In fact, it is possible to utilize the space afforded by such an establishment to great advantage in many ways, depending upon the size of the hotel itself.



Open shed, one end of which has been closed and a stove installed for heating purposes in cold weather

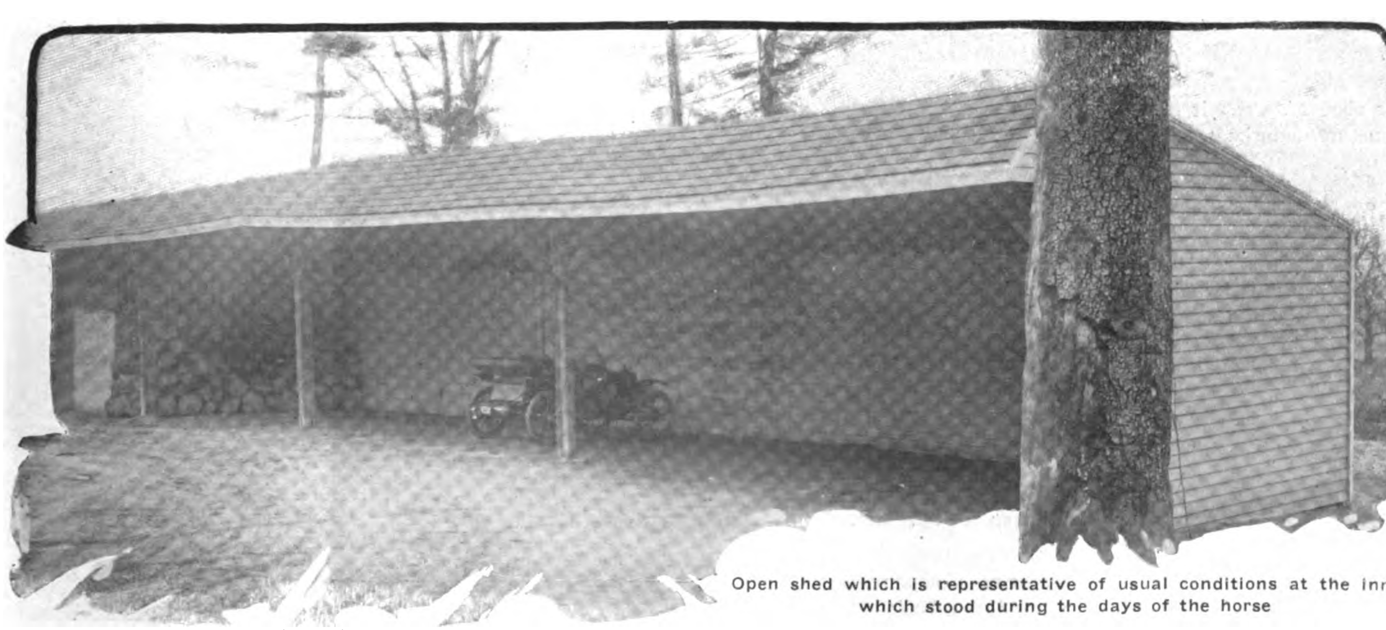


Large stone garage, formerly a stable, converted by innkeeper into a heated and commodious storeroom for cars

For the innkeeper who wishes to meet the situation as it now stands, there are many ways of protecting the car. An ingenious scheme which has been suggested is to arrange a number of portable light sockets. An electric heater is plugged into the line and placed against the radiator so as to maintain the water at such a temperature that the motor may be readily started. He may partition off a portion of his sheds or he may go to a greater expense and build a new garage designed specially to be heated. It is certain that any expense he may go to will bring him great returns if his resort is situated along the lines of main travel. It is just as important to have suitable arrangements for the conveyances of his guests as it is to provide the best of service and entertainment. There are many innkeepers who are automobilists themselves and who realize the ever-increasing number of winter tourists.

On a cold, clear winter night there are many who take a keen delight in a trip of 25 or 30 miles with a stop at some inn for refreshment. Many are deterred from stopping because they dare not leave their cars unprotected. This no doubt has a considerable influence on the number of cars which are stored, because it detracts from the pleasure of winter riding. In spite of the fact that a large number of the resorts have done absolutely nothing towards protecting the automobiles of their guests against the effects of cold, they enjoy a large patronage. This alone should show the tendency toward an increase in winter travel and it is strange that the wideawake proprietor has not more closely followed the interests of his best, and, in fact, only customers.

The automobile has ceased to be a horseless carriage, it is now at a stage where it is as much of a conveyance as the trolley or railroad. With the ever-increasing number of state roads more territory is being thrown open to it and its scope has been widened until in the more settled parts of the country it forms the ideal method of travel when the roads are not actually blocked by heavy snows or other causes. In the majority of our states the percentage of time that the roads are blocked is so small as to be negligible. Realizing this condition and also the necessity for adequate stations along the lines of main travel there is a golden opportunity for the inn to build itself up and to grow in the same manner as all year round traveling is growing. The surest way to help build up this condition is to supplement the good roads now found through every state by suitable protection and provisions for the car while it is at rest and sensitive to climatic conditions.



Open shed which is representative of usual conditions at the inn which stood during the days of the horse

Good Year for Goodyear

1912 the Greatest in History of Company Whose Factory Additions Amounted to $1,532,595

During Past Year Company Has Increased Its Capital from $6,000,000 to $15,000,000

NET income of the Goodyear Tire & Rubber Company for the year ending October 31, 1912, was $3,001,294. Other profits, chiefly on rubber contracts, amounted to $217,593 and the unappropriated surplus from previous operation is $1,856,888. The year proved to be by far the greatest in the history of the company and manufacturing operations were extended to such an extent that it was found to be advisable to increase the capitalization of the corporation. Hitherto the company has had a capitalization of $6,000,000, but during the past year this has been expanded to $15,000,000. The new stock consists of $4,000,000 of 7 per cent. cumulative preferred and $5,000,000 common. About $5,000,000 of the common stock has not been issued.

During the year dividends of $2,289,100 in common stock have been distributed and $139,604 has been paid to preferred shareholders.

The balance sheet shows assets of $13,818,214. The plant is listed at $3,855,569; actual cash on hand or deposit, $1,268,539; inventories consisting of crude rubber and other materials, $4,398,384. Patents are listed at $1 despite the fact that the company receives a large income from royalties on patents owned or controlled.

The list of liabilities include outstanding capital stock, par value $10,026,700; current debts, $1,116,406 reserves and the surplus noted above.

Additions to the plant during the year have been made at a cost of $1,532,595.

Reeves Goes to Hartford Company

Alfred Reeves, vice-president and sales manager of the United States Motor Company, and A. R. Gormully, general purchasing agent of the same corporation, have severed their connections with that company to engage in other work. Mr. Reeves has been elected vice-president and general manager of the Hartford Suspension Company, manufacturers of shock absorbers, electric starters and lighters and automobile specialties. He will remain with the motor company until after the coming shows.

Mr. Gormully has been elected treasurer of the Steinbock Engineering Company, which has been in course of development for about a year. It is announced that he will probably assume some more intimate connection with the industry in the near future.

Lion Company Confesses Bankruptcy

DETROIT, MICH., Dec. 9—A voluntary petition in bankruptcy was filed in the United States District Court here December 6 by the Lion Motor Car Company, Adrian, Mich., whose plant was destroyed by fire some time ago. C. L. Robertson, of Adrian, was named receiver by L. E. Joslyn, referee in bankruptcy, in the absence of Judge Tuttle. The concern's liabilities are given as $108,894.05 and the assets as $105,546.94, of which $86,727.91 is given as merchandise.

Receiver for Flanders Mfg. Co.

DETROIT, MICH., Dec. 7—Following a meeting of the board of directors of the Flanders Manufacturing Company December 4 at which plans for the continuing of the business were submitted by the creditors' committee, application was made on behalf of the Wagner Electric Manufacturing Company, St. Louis, Mo., by S. T. Douglass, an attorney of Detroit, before Judge Tuttle in the Federal Court in Bay City, Mich., to have a receiver appointed for the Flanders concern. The Detroit Trust Company was appointed, the bond being fixed at $50,000.

According to a statement of the Flanders company's affairs. which appeared in these columns, the concern's assets are greatly in excess of its liabilities, and its present financial distress is merely from the lack of ready capital. It is generally understood that the Pontiac plant is a money maker and that the straitened monetary condition is due to several other holdings. It is proposed to continue the business in the event that the contemplated refinancing and production plans are agreeable to the receiver.

Poss Company to Fight Bankruptcy

DETROIT, MICH., Dec. 9—As predicted in THE AUTOMOBILE last week, the Poss Motor Company has signified its intention to contest the granting of the involuntary bankruptcy petition which was filed by the Detroit Foundry Company and several other creditors in the United States District Court November 19. Denial has been made by the concern and twenty-four of its creditors that its affairs are such as to make it bankrupt. A fight in the courts is probable.

Receiver to Divide Atlas Money

INDIANAPOLIS, IND., Dec. 9—Fred C. Gardner, receiver for the Atlas Engine Works, has been authorized by the Superior Court to distribute the funds in his possession. In the final settle-

Automobile Securities Quotations

SAVE for a sharp bulge in Firestone, Swinehart and Miller which made new high marks for each of those stocks, the automobile securities market for the past week has been a fruitful field for the bears. The activity in those tire issues was accounted for on a variety of theories, but the main fact that stands out is that the buying was apparently by insiders. There was some talk of a merger but nothing definite developed. The buying orders appeared on Tuesday and various brokerage houses reported that quite an amount of the shares were picked up. Otherwise the market slumped badly in response to the general situation in financial circles, based upon European politics.

ment the common and preferred stockholders will get nothing and the bond holders of a bond issue of $1,050,000 will have to look to the property, which is now owned by the Lyons-Atlas Company, for their money.

The receiver has about $84,000, of which $20,550.92 will be used in paying the receiver and his attorneys. The balance, $63,459.89, will go to the merchandise creditors. The Lyons-Atlas Company, in keeping with the terms under which it acquired the property, has paid $31,500 interest due on a bond issue of $1,050,000, $6,500 judgments against the Atlas company, paid a debt of $105,000 secured by a bond issue and has paid debts secured by pledges of Atlas accounts amounting to $48,187.04.

—

Myers Heads Swinehart; Plant to Grow

AKRON, O., Dec. 9—Clifford B. Myers has been appointed general manager of the Swinehart Tire & Rubber Company to take the place of W. W. Wuchter, president of the company, who has acted as general manager.

It was announced today that the Swinehart company has plans under way for a material enlargement of the Akron plant. The present factory is in a business district in the city and as it is practically impossible to buy more land there, it is probable that a new factory will be built in the suburbs.

—

Crude rubber rose 4 cents at the week end, being above $1.11 for up-river fine, where the level had been at $1.07 heretofore. The firmer tone which recently developed in the leading crude rubber markets was still in evidence during the past week. Smoked sheets dropped 1-2 cent and pale crêpe rose 3 1-2 cents.

Market Changes of the Week

Few features in the market developed during the last week. In the rubber market, scrap rubber showed no change. With collections light the market remains in a firm position. Importers report a steady demand for all grades of foreign scrap. Cottonseed oil trading was of a routine character Tuesday with the increase of price from Monday failing to reflect any aggressive movement by either party. Though strong on Wednesday, it dropped to $6.25 and then rose to $6.29, a loss, though, of $.07 for the week. In the metal markets, tin and lead experienced slight losses, $.01 and $.02 1-2 respectively. In the lubricant markets, linseed oil, petroleum, Pennsylvania crude, and rapeseed oil, changed in prices, linseed oil dropped $.04, petroleum rose $.05, and rapeseed oil experienced a loss of $.04. Taken altogether the week has been one of unusual lack of activity in the metal, old rubber silk and lubricant markets.

U. S. Motors To Move

—

Preparations Are Being Made for the Removal of the Company to Detroit in the Near Future

—

This Will Place Administration Departments in Closer Proximity to Its Manufacturing Plants

FINAL preparations are being made for the removal of United States Motor headquarters from New York to Detroit. The date for the actual change is still unfixed but it is generally believed that it will be accomplished very shortly after the judicial sale has been made and reorganization finished.

During the past week a series of meetings has been held at headquarters behind closed doors and the announcement has been made that the few remaining office employees of the company will resign within a short time.

The removal of the company to Detroit places its administrative departments in closer proximity to its manufacturing plants and foreshadows renewed manufacturing activity at the quiescent factories of the company in the Detroit zone.

The affairs of the United States Motor Company await the judicial sale that has been decreed for January 8. In the meantime, manufacturing activities are at a low ebb. Save for such industrial work as is necessary to maintain the supply of parts for the repair of existing cars all the plants of the company are shut down except for the completion of the manufacturing schedules of 1912 and the continuance of the manufacturing schedules of the Maxwell Briscoe Motor Company, for 1913 and its experimental work for 1914.

The Brush and Sampson plants are idle except for the production of spare parts; the Columbia is finishing the last of its regular schedule; Stoddard-Dayton has finished its schedule. The three Maxwell plants, chief of which is at Tarrytown, N. Y., have about completed schedule. The Newcastle plant is inactive for the time being and the Providence plant is quiescent. The Thomas plant is completely shut down except the repair department.

Under order of court the issuance of $1,500,000 of receivers' certificates was authorized to commence the Maxwell manufacturing schedule for 1913, and much work has been done toward this end. So far the money used for the Maxwell program has come from other sources than the sale of the certificates.

Attorneys for the creditors state that upwards of 95 per cent. of the total claims against the company have been filed indicating an almost unanimous opinion in the minds of the creditors as to the feasibility of the reorganization plan.

The second call for 10 per cent. of the assessment levied against the stock has been made, but details as to the exact amount of stock deposited are lacking. It is said that it totals more than a majority.

No apprehension is felt among the various interested elements in New York with reference to the court action in bankruptcy in New Jersey.

It is pointed out that the New York court has possession of the assets and that the indicated program of sale will be carried out.

At the meeting of the sales and district managers of the company, those who represented districts in which the branch houses have been liquidated resigned automatically and the remainder considered the future in executive session.

Announcement has been made that C. E. Reddig, chief engineer of the Columbia Motor Car Company, and designer of the Columbia-Knight car, has resigned his position with that company, and has been made assistant chief engineer of the Timken-Detroit Axle Company, with headquarters in Detroit, Mich.

S. A. E. Program for Winter Meeting Fixed

Sessions To Last 3 Days—New Members in Board of Trade—Studebaker Branch Managers Meet

New Morgan & Wright Buildings Will Have More Than 1,000,000 Square Feet of Floor Space

DETAILS of the program to be followed at the annual meeting of the Society of Automobile Engineers are contained in the current issue of the bulletin published by that organization.

The sessions will be held at the new Hotel McAlpin and will commence January 16 at 9:30 o'clock in the morning with a business and professional meeting. There will be a professional session at 2 in the afternoon and the Commercial Vehicle will be the subject of discussion and consideration at the evening meeting.

Friday, January 15, will have professional sessions at 9.30 a. m. and 2 p. m. and in the evening the annual banquet will be held at the McAlpin. Saturday morning's professional session will close the convention.

Prior to the opening meeting the Standards Committee will assemble on Wednesday at the headquarters of the organization to receive the presentation of the reports of subdivisions that have met with the approval of the Council.

Among the papers and reports scheduled are the following: Reports: Broaches, C. W. Spicer; Ball and Roller Bearings, David Fergusson; Frames, J. G. Perrin; Miscellaneous, A. L. Riker; Sheet Metals, T. V. Buckwalter; Motor Testing, John O. Heinze; Nomenclature; Springs, Harold L. Pope; Truck Standards, William P. Kennedy; Wheel Dimensions and Fastenings for Tires, William P. Kennedy, and Aluminum and Copper Alloys, William H. Barr. All of the above are formal reports of divisions of the Standards Committee and will be presented by the various chairmen as noted.

Among the formal addresses scheduled are the following: Effect of Relation of Bore to Stroke in Automobile Engines, John Wilkinson; Stability of Automobile Propeller-Shafts, J. M. Thomas; Methods of Brake Capacity Determination, S. I. Fekte; Leaf Springs, L. J. Lane, and Standardization of Drawings, George W. Dunham.

Numerous other optional papers have been listed in case the opportunity is afforded for presentation.

Board of Trade Elects Four

Four new members have been elected by the Automobile Board of Trade and have qualified for membership in that organization. They are as follows: Federal Motor Truck Company, Inter-State, Imperial and Stutz.

The accessions bring the membership of the A. B. of T. up to sixty-three, which is a new high record for that association. The present tendency to be noted in the national organization is to absorb individual members of the National Association of Automobile Manufacturers, so that when the time arrives for the merger of the two bodies the change will not be radical as far as the members are concerned.

Studebaker Staff Holds Conference

SOUTH BEND, IND., Dec. 9—Last Saturday a special train pulled on the siding of the Studebaker Corporation plant bearing a party of Studebaker officials from the automobile division in Detroit. The group included the thirty branch managers whose annual meeting has been in progress during the week. The afternoon was devoted to conferences under the direction of General Manager Gunn. In the evening a banquet was served, after which the party embarked again on the special train for Detroit.

The party included the following, most of whom returned to Detroit: F. S. Fish, president; C. Studebaker, Jr., first vice-president; G. M. Studebaker, second vice-president; W. R. Innes, assistant treasurer; Scott Brown, secretary; J. E. Spencer, assistant secretary; J. N. Gunn, general manager; A. H. Brown, Portland; B. R. Person, Memphis; L. J. Oliver, Los Angeles; C. N. Weaver, San Francisco; N. S. Riley, Kansas City; R. L. Sutherland, Indianapolis; J. A. Graham, Minneapolis; L. A. Keller, Omaha; P. E. Hawley, Boston; O. C. Reed, Birmingham; B. T. Kingsman, Buffalo; G. W. Hanson, Atlanta; L. Markle, Chicago; C. A. Quigley, Salt Lake City; J. O. Hahn, Cleveland; C. W. Hartman, Dallas; J. C. Beck, Jr., Denver; A. K. McLuney, Detroit; W. C. Vleit, Fargo; H. R. DeGroat, Philadelphia; G. H. Phelps, New York; W. W. Beeson, Louisville; C. J. Simons, St. Louis; E. H. Habersham, Washington; G. C. Nichols, Spokane; C. H. Snoke, Sioux Falls; H. T. Myers, South Bend; H. L. Kuhns, New York Vehicle branch; R. L. Messimer, J. A. Austin, R. H. Booth, Theodore F. MacManus, H. A. Biggs, Hanson Robinson, O. S. Wilson, W. B. Brady, E. R. Carpenter, H. F. Wellington and H. E. Dalton.

M. & W. to Add Sixteen Buildings

DETROIT, MICH., Dec. 9—Permits have been issued to the Morgan & Wright Company for the erection of sixteen new factory buildings to take care of the prospective increase in output of pneumatic tires. It is stated that when these additions have been completed about 5,000 tires will be turned out per day and the working force doubled.

The new structures will vary in size from 2,000 to 121,000 square feet, the largest being 60 by 230 feet and six stories high. The new buildings will swell the total Morgan & Wright floor space to over 1,000,000 square feet and will make this plant the largest in the world, it is said. The Morgan & Wright Company is a subsidiary of the United States Tire Company.

Receiver for Whitesides Truck

INDIANAPOLIS, IND., Dec. 9—The affairs of the Whitesides Commercial Truck Company have reached the Henry County Circuit Court, where Mark Davis has been appointed receiver for the company, which has a plant at Newcastle. The plant has been closed for some time and the receiver is to wind up and dispose of the business as rapidly as possible. The receivership proceedings were brought by the stockholders who have been unable to agree as to how the business should be conducted. The company was founded by V. M. Whitesides, who was general manager until he withdrew from the concern a few weeks ago.

Massachusetts Fees Jump $140,000

BOSTON, MASS., Dec. 7—The Massachusetts State Highway Commission closed its fiscal year November 30. The gain in the number of cars shows a jump of more than 11,000, while the increase in fees represents something like $140,000.

In 1911 there were 38,907 cars registered from which the commission got $380,760, while this year 50,132 machines were put on the books for which $492,482.50 was collected. The manufacturers and dealers helped to swell the fund, too, for last year with only 870 the state got $24,849, while for 1912 the figures show a gain to 1,114 from which $27,157.50 was secured. This does not include nearly $5,000 for additional number plates for dealers.

Next in importance in revenue comes the operators' licenses that brought in this year $29,386, compared to $22,122 in 1911. The renewals of licenses was good for $16,127.50 this year against $12,672.50 last year. The chauffeurs poured in $11,140 for licenses and $7,063.50 for renewals, while a year ago the figures were $8,366 and $5,680.50, respectively.

Then there were the examinations that were good for $14,036, while in 1911 $12,274 was received. The increase averages about 25 per cent. all along the line.

This year there were within a few hundred cars rating under 30 horsepower registered as many as there were of all classes a year ago. The cars under 20 horsepower getting the $5 rate totaled 15,774. Those between 20 and 30 getting the $10 rate numbered 22,265. Some got proportional rates between due to change of ownership.

Chauffeurs contributed $32,239.50 this year against $25,000 in 1911. And the drivers of horse-drawn vehicles numbering thousands never have to pay a cent to earn their living. The commission is now receiving applications for 1913 numbers.

Comparative figures showing the increase in registrations and finances from the motor industry in the Bay State in 1912 over that of 1911 are as follows:

	1911	1912	1911	1912
Automobiles	38,907	50,132	$380,760.00	$492,482.50
Motor cycles	3,685	5,034	7,030.00	9,640.00
Manufacturers, dealers	870	1,114	24,849.00	27,157.50

Chauffeurs' licenses	4,183	5,570	8,366.00	11,140.00
Operators' renewals	25,345	32,255	12,672.50	16,127.50
Chauffeurs' renewals	11,361	14,127	5,680.50	7,063.50
Examinations	6,137	7,018	12,274.00	14,036.00
Miscellaneous cash	...	...	3,663.95	9,200.44
Fines	...	...	26,744.50	29,108.00
Total			$504,162.45	$645,344.44

Balkan War Gets the Angora

SAVANNAH, GA., Dec. 9—The possibility that the Balkan controversy and the attending depression of Turkish commerce will result in the price of automobile tops advancing is suggested by the fact that much of the material now used in making the high class motor car top covering is of mohair, which is imported from Turkey, the home of the famous Angora goat.

With all the mammoth automobile business of the United States encouraging its manufacture, the best mohair material for their use is not made in the United States. The material is rubberized after it reaches America, and a lining added to it before it goes to the factory to go over the framework of the automobile top.

U. S. Motor Branch Dissolved

WASHINGTON, D. C., Dec. 9—The United Motor Washington Company, a branch of the United States Motor Company, has been dissolved, the Maxwell agency being given to H. B. Leary, Jr., and the Columbia to the Dupont Garage Company. Leary has leased the company's salesroom and the Dupont company has taken Leary's old quarters at 1317 Fourteenth street, N. W. The latter also handles the Rambler and Mitchell. John R. Thomas, former manager of the United Motor Washington Company, has been promoted to the managership of the Philadelphia branch.

THE FLEX-O-FILL CORE COMPANY has been incorporated under the laws of New York for $50,000 to manufacture a tire filler for which patents have been asked. The principle involved is that of applying pressure to the circumference of the core in such a way that wounds in the casing will not cause the destruction of the shoe. The substance used for the filler is designed to heal up small wounds by automatic action. The incorporators are G. Osborn, L. McCready, M. A. Noble, and the offices and factory of the company will be in New York.

THE ANNUAL BEEFSTEAK DINNER of the Big Village Motor Boosters will be held January 14, during the opening week of the national annual show. The place for holding the function has not been fixed but a meeting of the organization has been called this week to arrange that detail and other important matters with reference to the program.

World's Records Go at Brooklands Track

New Figures for the 50-Mile Distance Established by Christiaens in an Excelsior—Hemery in Lorraine

Record for 6-Hour Run Better by More Than 66 Miles by Hemery—Other Times Bettered by Margins

LONDON, Dec. 2—There has been a revival of record breaking attempts in England, with the result that many of the old figures that have been standing as world's records have been eliminated. The world's record for 50 miles was broken last week by an Excelsior car of 60 horsepower, driven by J. Christiaens. He made two attempts to cover 100 miles in the hour and but for a slight mechanical breakdown in the first attempt and tire trouble which caused him to stop prematurely on the second run there is little doubt that he would have accomplished his object, as his speed averaged for the distance he actually covered well over 100 miles an hour. In the first attempt he covered the first lap in 1 minute 56 1-5 seconds from a standing start, and the second and third laps were covered in 1 minute 36 seconds, giving an average speed of 103.76 miles per hour. In the second attempt, although he failed in covering the hundred miles, he established new figures for the world's record at 50 miles, covering that distance in 29 minutes 18.45 seconds, which gives an average speed of 102.36 miles per hour, easily beating the previous best of 97.17 miles an hour recently set up by a Vauxhall car.

In the next series of world's records, Victor Hemery, of Continental fame, and who drove the 84.8 record-breaking Benz over the flying 1-2 mile on the Brooklands track in November, 1909, at a speed of 127.9 miles an hour, thereby not only establishing the fastest speed ever attained on the Brooklands track, but also creating a world's record that has stood ever since, took the wheel of the car. On this occasion, however, he was driving a 60-horsepower Lorraine-Dietrich and succeeded in establishing world's records from 1 hour to 6 hours. He covered 518 miles 312 yards at an average speed of 86.36 miles per hour, thus easily beating the figures put up by the 30-horsepower Sunbeam car of 451 miles 445 yards at an average speed of 75.2 miles an hour. He also established new figures for all intermediate long-distance records except the standing start 50 miles, which is fully dealt with above, established by the Excelsior car, and the 300 miles which C. M. Smith put up on a 60-horsepower Thames car, averaging 85.6 miles per hour.

Having failed to establish a record in the first 50 miles, Hemery deliberately stopped at the end of 5 hours in order to make a fresh attempt for the distance in the last and sixth hour. He began in fine style, lapping the course at a speed well over 100 miles an hour, and when everything seemed smooth for new figures he experienced tire trouble. Nevertheless, despite these halts, he improved on the old 6-hours' world record by no less than 66 miles 1,627 yards.

The new figures now read: 1 hour, 97 miles 1,037 yards, against the old record of 92 miles 797 yards; 2 hours, 189 miles 1,747 yards, against 173 miles 810 yards; 3 hours, 284 miles 817 yards, against 261 miles 1,633 yards; 4 hours, 344 miles 1,344 yards, against 319 miles 242 yards; 5 hours, 422 miles 1,574 yards, against 391 miles 1,429 yards, and 6 hours, 518 miles 312 yards, against 451 miles, 445 yards.

He covered 100 miles in 1:01.:27.69; 200 miles, 2:05:56.73; 400 miles, 4:34:23.87, and 500 miles in 5:48:38.87.

Decorations of New York Show Superb

White and Crystal Color Scheme To Be Feature at Garden and Mural Landscapes at Palace

Sixty-Eight Truck Manufacturers Have Already Contracted for Space at Commercial Vehicle Exhibition

DECORATION and esthetic setting for the annual automobile shows commands a position of more and more importance each year and for 1913, the management of the New York show which will be held at Madison Square Garden and Grand Central Palace has paid more attention to the matter of decorations than ever before.

White and crystal will be the color scheme at the Garden, while mural landscapes illustrating scenes significant to automobiling will be the keynote of the Palace decorations.

Preparations for the Garden division of the show require much more labor and expense than those for the Palace. For instance, something like 200 tons of steel and 1,000,000 feet of lumber are required to reconstruct the interior of the hall in anticipation of the show. Two great freight elevators must be installed to hoist exhibits above the main floor. Part of the mission of the decorative plan is to conceal the rough corners necessitated by the alterations of the building.

The crystal feature of this year's plan will be embodied in three giant chandeliers and thirty smaller ones, suspended from the dome. Around the walls many thousands of square feet of mirrors will be placed and the sculptural effects will be carried out in white. Some of the details of the plan still remain to be worked out as far as the Garden decorations are concerned but it is certain that the lattice used last year in conjunction with ornate lamp-posts to separate the exhibits will again be favored. Garlands of flowers and greenery will be intertwined along the balconies and looped in front of the pillars that support the elevated platform.

At the Palace the main floor will show scenes on Long Island, at Delaware Water Gap, in the Berkshire Hills and along the Hudson. On the mezzanine floor, western views will be displayed.

The pergola style of decorative framework will be used in connection with trellis and garlands.

The main and mezzanine floors will be used for complete cars while the accessory and motorcycle show will be in the balcony.

The decorative features of the Palace are pronounced by the management to be the finest ever used in that building.

All the preparations for the extensive alteration necessary to convert the Garden into a fitting place to hold its section of the automobile show have to be made in advance. Each girder and stanchion must be prepared and numbered so that when the word is given it can be installed. As the big hall is frequently used for other shows up to the week before the opening day, the work of getting ready for the automobile show requires work at high pressure. The preparatory work commenced several months ago and in a big loft near the building the sky, which will be used to cover the ceiling and girders of the Garden, is now being painted. The rug that was used last year has been discarded and the covering at the coming show will be of soft blue in simulation of the real sky.

As usual, the signs of the individual exhibitors will be uniform and will harmonize with the decorations.

Twenty-one different makes of motor wagons and trucks never before exhibited in New York will be displayed in the commercial car section of the New York Automobile Show during the second week, from January 20 to 25. All of these will be located in the New Grand Central Palace. This year the electric vehicles will all be grouped together in the Palace, so that a few of the early truck makers, including several real pioneers in the field, will be found in company with the newest makers in the fold.

Sixty-eight commercial car companies already have contracted for space at the Show, 5 weeks before it opens, which is four more than the actual number of exhibitors at last winter's shows in the two buildings. There will be additions no doubt that will bring the list to between seventy and seventy-five this winter.

Of the score of makes not previously exhibited, one-half are entirely new to the market, never having been exhibited before in any show. Most of the others are western products, for which their makers are seeking Eastern recognitior.. Some of them have been in the market for a number of years and have made good in exacting service over poor roads in the central states.

The new makes include both gasoline and electric vehicles. They embrace all sizes, from delivery wagons of 1,000 pounds capacity to 6-ton trucks. An even greater range of size will be found among the older makers, ranging from about 800 pounds to 10 tons load capacity.

While a majority of the models on view will be fitted with standard bodies suitable for the commoner lines of business, there will be a great diversity, from florists' wagons and motor ambulances to motor fire apparatus, automatic dump trucks and so forth.

Time Schedule of M. A. M. Show Meetings

Detailed schedule of the various meetings to be held during the coming show season by the Motor and Accessory Manufacturers has been announced as follows:

Tuesday, January 14 at 10 o'clock a. m.: Meeting of the executive committee at headquarters.

Tuesday, January 14 at 3 o'clock p. m.: Meeting of the board of directors at headquarters.

Wednesday, January 15, 5:30 o'clock p. m.: Tenth annual meeting at Waldorf-Astoria.

Wednesday, January 15, 8 o'clock p. m.: Fifth annual banquet at Waldorf-Astoria.

Thursday, January 16, 2:30 o'clock p. m.: Board of directors at headquarters.

Washington Dealers Split on Show

WASHINGTON, D. C., Dec. 8—Plans for the motor car show scheduled for February 5-8 are progressing satisfactorily, despite the fact that sixteen of the leading dealers have declined to take part. Chairman T. Oliver Probey claims that more than one-half the space has been sold, it being understood that a number of outside concerns will take space in order to introduce their cars here and thus pick up an agent. A portion of the hall will be devoted to an exhibit of trucks. E. A. Garlock has been elected secretary of the show committee.

The opposition dealers, who are planning a carnival or opening week Feb. 10-15, are going ahead with their arrangements. A meeting of the committee in charge of the affair, of which J. M. Stoddard is chairman, will meet this week to formulate further plans for the carnival.

Club Garage for Quaker Show

PHILADELPHIA, Dec. 7—With but few exceptions members of the Automobile Club of Philadelphia are heartily in favor of the proposition to lease the building of the organization at Twenty-third and Market streets to the Philadelphia Automobile Trade Association for the holding of the annual automobile show which opens on January 18. This practically assures the holding of the event there, in which case it will be the largest and most representative of the industry ever held under one roof in this city, as ample accommodations will be at the disposal of the Show Committee of the Trade Association to take care of additional exhibitors, and a larger number of cars will be on view than ever were assembled before.

Pending final acceptance of the plan to use the club's garage for the show, plans are being worked out by the Trade Association to make it the best ever. These are, as yet, only in a formative state. As has been the custom, the exhibition will extend over 2 weeks. So far, no changes in the yearly routine have been announced outside of the fact that the first week will be devoted to gasoline pleasure cars, electrics and accessories, the second week being confined exclusively to commercial vehicles. Heretofore the electrics have been on view the second week, in conjunction with the trucks, owing to lack of room.

Next Saturday afternoon from 2 until 6 o'clock, the cornerstone ceremonies and formal opening of garage and clubhouse of the Automobile Club of Philadelphia will take place. Men prominent in the automobile world will be present and make addresses.

Chicago Truck Show Growing

Nine more motor truck and wagon makers have contracted for space at the National Automobile Show at Chicago during the past week. This brings the list of complete vehicle exhibitors up to sixty-nine—one more than in the New York show.

As all of the ground floor space in the Coliseum, Annex and First Regiment Armory has been allotted, it has been found necessary to set aside a large section of the second floor of the Annex for the display of the lighter types of motor wagons. This embraces all the space on the south half of the center aisle formerly devoted to motorcycles.

Among this year's exhibitors are sixteen companies that never have shown their product at Chicago. All but four of these are new makers whose machines are just coming into the market for the first time. Eighteen of the Chicago exhibitors have made no arrangements to display in New York this winter. Most of these are mid-western makers, located principally in Chicago and in other Illinois, Wisconsin, Michigan, Indiana and Ohio cities.

The week's additions to the list are as follows:

Harder Fireproof Storage Warehouse Company	Chicago, Ill.
Kentucky Wagon Manufacturing Company	Louisville, Ky.
H. J. Koehler Sporting Goods Company	New York City
The Lansden Company	Newark, N. J.
Mais Motor Truck Company	Indianapolis, Ind.
Mercury Manufacturing Company	Chicago, Ill.
Mogul Motor Truck Company	Chicago, Ill.
Stewart Motor Corporation	Buffalo, N. Y.
Ware Motor Vehicle Company	St. Paul, Minn.

The M. & P. Electric Car Company and Transit Motor Truck Company have dropped out.

Milwaukee Show Opens January 11

MILWAUKEE, WIS., Dec. 9—The fifth annual Milwaukee motor show, to be given in the Auditorium from January 11 to 17 inclusive, will be under the auspices of the Milwaukee Motor Show Association, a new corporation. Blank applications for space have just been issued. The show will open on Saturday night, January 11, at the same time that the national pleasure car show opens in New York, and will close on Friday evening, January 18.

Tri-City Show February 19-22

DAVENPORT, IA., Dec. 9—At a meeting of the Tri-city Auto Dealers' Association held at the New Kimball in Davenport last week the date for the annual show was set as February 19, 20, 21 and 22 at the Coliseum. The annual meeting of the association was held at the same time and officers elected as follows: President, G. F. Burmeister, Davenport; vice-president, Emil Buck, Davenport; secretary, Webb Mason, Davenport; directors, G. F. Burmeister, Emil Buck and Webb Mason, Davenport; W. C. Totten, Rock Island, and Fred R. Young, Moline.

Paris Salon Opens With 565 Exhibitors

Clean Sweep for Long Stroke Motor—Six Types with Sleeve and Slide Valves Shown

After Lapse of 2 Years Tremendous Enthusiasm Manifested —Twelve American Makes on View

PARIS, Dec. 9—*Special Cable*—President Fallieres gave the signal for opening the automobile salon Saturday morning at 9 o'clock and since then the French public, reinforced by delegations from all the countries of the world in which automobiles are made, thronged the Grand Palais.

The show is pronounced the greatest and finest ever held and the expressed opinion of many of the visitors coincides with the French opinion on the subject.

There are 565 exhibitors and of these there are over 200 displays of French automobiles. England is represented by thirty-four makes, America by twelve, Germany by nine, Italy by eight, Belgium by nine, and Switzerland by four. In all there are over 275 different makes of automobiles on display.

The Grand Palais floor measures 260,000 square feet and it is all occupied by the automobile exhibition.

After a lapse of 2 years since the last automobile show was held in Paris, the enthusiasm is very great. In fact, it has been stimulated to such an extent that the holding of a show annually is practically assured.

Various propositions have been made to hold a pleasure car show every other year with a commercial vehicle exhibition on the alternate years. This plan has been viewed with favor by the parent organization behind the shows, but the immense favor with which the salon has been received makes it almost certain that a yearly pleasure car show will result, the popular demand for it appearing to be strong.

The overflow show includes displays by more than 200 manufacturers who were unable to crowd into the Grand Palais. The overflow show is housed in the Jardin de Paris, a huge pleasure garden that is usually closed at this season of the year.

PARIS, Dec. 10—(*Special Cable*)—Paris sprung a surprise on Olympia by making a clean sweep for the long stroke motor. Not counting the American exhibits there were 321 four-cylinder models, twenty-six sixes, eleven twin and fifteen one-lunger models. The motor with the smallest bore had cylinder dimensions of 50 by 100 millimeters (1.97 by 3.94 inches). The motor with the longest stroke had cylinder dimensions of 110 by 200 millimeters (4.42 by 7.88 inches). An idea of the relative sizes of the motors may be gained from the following: There were seven motors of 60 millimeters bore, forty of 65 millimeters, thirty-one of 70 millimeters, sixty-two of 75 millimeters, seventy-two of 80 millimeters, eighteen of 85 millimeters, fifty of 90 millimeters, seven of 95 millimeters, thirty-eight of 100 millimeters and thirty-seven between 100 and 140 millimeters. Thirty-three motors have a stroke-bore ratio of 2 to 1 and 50 per cent. have 1.5 to 1 stroke-bore ratio. The balance are scattered but none were square, bore equalling stroke with the exception of the Knight sleeve motors.

Six types of sleeve and slide valve motors were exhibited at the show, the Knight proving the most popular and attractive to makers. The small, well-made poppet valve is proving itself silent, economical of fuel and generally efficient. A noticeable feature was the effect of the war scare on purchasing, a great retarding influence being exerted.

Carburetted Alcohol, Harmless, Rich in Calories and Stronger than Gasoline, Developed at French Chemical Plant and Tried Out in Ordinary Motors—Wobble-Disk Crankshaft-Drive in Aviation Motor—Convenient Hoist for Factory Use

CHECKING Rise of Gasoline Prices by Manufacture of Competing Fuels, Especially Carburetted Alcohol— The strong efforts made in Europe to emancipate the employment of all internal-combustion motors—from the Diesel ship motor and stationary power plant to the diminutive bicycle motor—from their dependence upon imported and especially American fuels, are taking more and more definite forms and promise eventually to relieve the American supply of the European demand, thereby removing one reason for the constantly increasing market prices and creating means by which a direct competition with gasoline and kerosene may be promoted even in the American home market. The fact that the Diesel motor has already been made independent, with the result of forcing the German-American oil syndicate to moderate the prices of crude oils, has greatly encouraged this movement for nationalizing the fuel supply by technical means, and it is expected that sharp import duties will be resorted to in some of the European countries to help out the national product, as soon as this may be done without hardship to the consumers.

In Germany, where the original movement for utilizing alcohol and carburetted alcohol was at one time very strong and has left sad memories of technical and financial disappointment, so far as the use of these fuels in automobile motors is concerned, the leaders of the movement have turned to benzol, and the manufacture of this distillate of coal has been so organized that a minimum output of 27 million liters annually has been guaranteed the consumer. In England, where import duties play no part, the efforts are centered upon the development of carbureters and motors in which kerosene, benzol and gasoline may be used optionally.

From France a new method for the carburetion of alcohol is announced which will also begin to interest the United States as soon as the expansion of all motoring interests shall have influenced public opinion sufficiently to warrant the removal of govermental interference with the free production of alcohol whether pure ethyl or denatured. The restrictions imposed by the Internal Revenue laws and the supplementary enactments relating to industrial alcohol and the public supervision of the denaturing processes, by which after all a substance is produced which cannot be utilized economically in any motors of ordinary construction, operate at present as a brake upon all initiative by which the cost of production of alcohol, and of any suitable fuel of which it might form a part, could be reduced to its minimum. Similar factors, it is noticed, are at work in European countries, and the condition for progress is therefore the actual production of an alcohol fuel which can compete on its merits and which the public will demand.

THE NEW PROMISE OF CHEAP ALCOHOL FROM CORN

Maurice de Keghel, a prominent chemist and manager of the French Wood Impregnation Company sets forth some interesting details on this subject of producing a really suitable motor fuel from alcohol, and the substance of his article is presented in the following with a few abbreviations at technical points.

The industrial production of alcohol has entered upon an entirely new phase since Stewart's discovery with regard to the use and harvest of Indian corn. The Stewart process is simple. It consists in detaching the ear from the stalk as soon as the grain is milky. This results in an indefinite prolongation of the life of the plant and a constant and gradual increase of the sugar-content of the stalk until it rivals that of the sugar cane. The milky ear itself contains more than 20 per cent. of fermentable matter, and one-half of the weight thereof can be turned into alcohol while the rest forms a nutritious bran mash for cattle. It is highly important that Indian corn can be raised to this degree of maturity even in far-northern countries.

According to Dupont, in *Revue Mensuelle* for June, 1912, corn harvested according to the Stewart method yields 2000 liters of alcohol per hectare of land (about 203 gallons per acre) and in addition 13000 kilograms of sugar which may be used as such or converted into alcohol.

The possibility of cheap production of alcohol may, from these data, be considered as established, but alcohol in itself is a feeble fuel and also attacks the metal of a motor. It has been shown that ordinary alcohol, or alcohol denatured with wood alcohol, cannot compete with gasoline or benzol. It must be enriched, and then two questions arise. First, with what other fuels must it compete and, secondly, how shall it be enriched in order to become most valuable and economical?

SHORTCOMINGS OF DIFFERENT FUELS AND MIXTURES

With regard to gasoline it must always be a drawback to its universal use that only about 6 per cent. of crude petroleum can be converted into this fuel and that American petroleum is the only kind which produces the best grade; the supply falls short of the demand, and the high price is aggravated by import duties. In case of war the supply is threatened. It can neither be the standard fuel in the long run nor the substance with which alcohol should be enriched.

Benzol, which is spirit of coal tar, can never supply the market as the production of it is limited by nature to a quantity incomparably smaller than that of gasoline. It is also objectionable by entraining corrosive elements in the distillation process. which it is costly to remove, by having a very high freezing point and by the strong odor of its exhaust gases.

By mixing benzol and alcohol in equal parts, as has been done in order to enrich the alcohol, a fuel is obtained in which the disadvantages in other respects of both constituents are preserved. This mixture is therefore little used.

THE TECHNICAL REQUIREMENTS

In seeking for a new kind of carburetted alcohol it has been the object to produce a homogeneous fluid with physical and chemical characteristics of its own and, of course, having none of the objectionable features of other fuels or compounds. The fuel which has resulted from these efforts contains 70 per cent. of alcohol in which elements have been absorbed from coal tar. from wood tar, from white spirit, from crude Galician petroleum and from pyridine. The preparation involves the five processes of mixing, distillation, neutralisation, redistillation and carburetion.

DESCRIPTION OF THE NEW PROCESS

The first process consists in mixing 60 parts of 93 deg. alcohol, 23 parts of wood tar and 17 parts of coal tar and heating the mixture, which is thoroughly stirred, slowly to 90 deg. C. in a still. The distillate is gathered by condensation in a cooling coil. It gives a plainly alkaline reaction and emits an odor resembling at once that of creosote and that of benzol, and this odor remains with the product throughout the subsequent processes. The distillation yields from 65 to 67 per cent. of the total weight of the mixture from which it is made and grades 90 deg.

The residue of this distillation has a special value for the preservation of wood and cordage. The tars in it have acquired new properties in the process, the corrosive and the hygroscopic elements disappearing. By adding pitch and white spirit turpentine in suitable proportions this residue forms an excellent and very adhesive black coating for metals. On the other hand the residue may be used for the manufacture of colors, as if the tars had undergone no change.

The distillate has a greenish yellow color and holds in solution a considerable proportion of ammoniacal compounds to which its alkaline character is due. The next process consists in transforming these compounds by chemical means into salts which are insoluble in alcohol and which also have an independent commercial value. Phosphoric acid has been found the best means to this end. It causes the formation of a very stable phosphate of ammonia which is precipitated in snow-like crystals. This is removed by decantation (pouring the liquid slowly away from the precipitate) and filtration and amounts to 0.6 to 0.7 per cent. of the neutralized mass. The liquid is slightly acid after this process, however, because phosphoric acid had to be used in slight excess over the alkalinity which it was to remedy, and it is therefore now redistilled, this process resulting in a strictly neutral alcohol of 93 deg. and of a density close to 826. When cooled to minus 25 deg. C. it does not separate in the least but remains homogeneous. Its denaturing elements constitute 3 per cent. of its weight, and it is found absolutely impossible to remove them or the odor which they cause. Its appearance is greenish yellow and fluorescent. Any fraudulent use of it would be very easy to detect by reason of the presence of compounds, such as rosaniline and pyridic bases, which give constant and characteristic reactions under test.

It is this alcohol which serves for the preparation of the carburetted alcohol. Extensive experiments were conducted at the shops of Henri Mers to determine the best proportion for admixture of enriching hydrocarbons, and 35 per cent. was found to give the best average results. The carburetting process consists in the distillation of the prepared alcohol in the presence of hydrocarbon compounds which part with some of their volatile constituents and in which some of these volatile constituents during the condensation form a stable chemical combination with the prepared alcohol, so that the final product is completely homogeneous and has a fixed distillation point. And it was found that compliance with this requirement, as expected, also resulted in a fuel of extraordinary power-producing properties, when used like gasoline in ordinary motors.

CARBURETTING THE PREPARED ALCOHOL

In the actual process, 66 parts of the prepared alcohol is mixed in a large closed vat, provided with a stirring tool, with 19 parts of Galician crude oil, 13 parts of white spirit and 2 parts of pyridine. The stirred mixture is left alone for 30 hours and is then distilled at 77 to 81 deg. C., yielding at this heat an average of 86 to 88 per cent. of the total mixture. This distillate grades at 95 deg. on the alcoholometer and is the carburetted alcohol ready for use in motors.

The assimilation of the crude oil is particularly favored by the presence of the pyridine which is a remarkably energetic solvent and a veritable extracting agent in separating the hydrocarbon elements from the crude oil. By its use, 39 to 40 per cent. of the crude oil is absorbed.

The residue represents usually 12 to 13 per cent. of the mixture. It has peculiar properties. Unlike the crude oil from which it is mostly derived, it cannot be coked. While the naphtaline has been removed from it, it is easily solidified and should make an excellent briquetted fuel, especially for marine purposes. The odor of the crude oil has partially disappeared from it.

The carburetted alcohol has a density of 826 at 15 deg. C., a fluorescent greenish-yellow appearance and an odor calling to mind both creosote and gasoline. A few drops of it rile water. It is strictly neutral and therefore harmless to the metals of the carbureter and the motor. The weight of the coke from it does not exceed 23/10,000 parts of 1 per cent. The average solid residue is .0003. This explains why it does not foul a motor. Its inflammability begins at minus 7 deg. C. and it is practically unfreezable, a temperature of minus 25 deg. C. causing no change in its action. It contains an average of 8030 calories and the exhaust from it is neither odorous nor smoky. Its efficiency as a source of power in automobile or stationary motors of standard design exceeds that of gasoline or benzol by about 60 to 70 per cent., according to the tests made at the Henri Mers shops.

COST OF PRODUCTION OF THE NEW FUEL

With a cost of production for 95 deg. alcohol of 30 francs per hectoliter, which is more than the actual cost at this moment though far from the exchange quotation, and with by-products which more than pay for all the cost of preparation and distillation, the cost of production of the carburetted alcohol may be figured as 27.30 francs per hectoliter, basing the calculation on a daily production of 65 to 70 hectoliters. [This cost which equals about 22 cents per gallon would perhaps be sufficiently low to establish the product on a competitive basis in Europe, considering the claimed power-efficiency of 60 to 70 per cent. in excess of that of gasoline, and would begin to interest America in a practical manner if the cost of production of the alcohol base were reduced to 10 cents per gallon, allowing in that case for a hundred per cent. of expense in handling the product commercially.—Ed.]—From *Revue de Chemie Industrielle*, November.

New Motor Types—At the recent aviation show in Paris several motors were exhibited which, though intended mainly for aviation purposes, embody new design features which are applicable to motors in general. Among these, several Canton-Unné motors made by the Emile Salmson firm attracted wide attention, partly by reason of their special design and select workmanship and partly because it was known that they operate satisfactorily in practice. One was a 7-cylinder water-cooled star-shaped motor of 80 horsepower with exposed central crankchamber; anothed a 9-cylinder fan-style motor of 300 horsepower weighing 450 kilograms, also water-cooled; still another a 9-cylinder motor with horizontal cylinders and the vertical motor shaft connected by a reducing gear inside of the crankchamber with a horizontal propeller shaft. But these types had been before the public for some time, while the fourth type shown was quite new and remarkable by its compactness and the adoption of a certain system for transforming the reciprocating motions of the pistons into rotary motion of the crankshaft which was brought out many years ago in an American patent for a hydraulic transmission and is at present copied and perfected in a hydraulic transmission known as the Williams-Janney and made by the Delaunay-Belleville company of France. The principle of the motion is public property. The Salmson motor in which this principle is utilized has 7 horizontal and parallel cylinders arranged as the cartridge chambers in the barrel of a revolver. Each of the cylinders has a central combustion chamber and two pistons which are moved by each explosion in opposite directions. At the ends of the cylinders

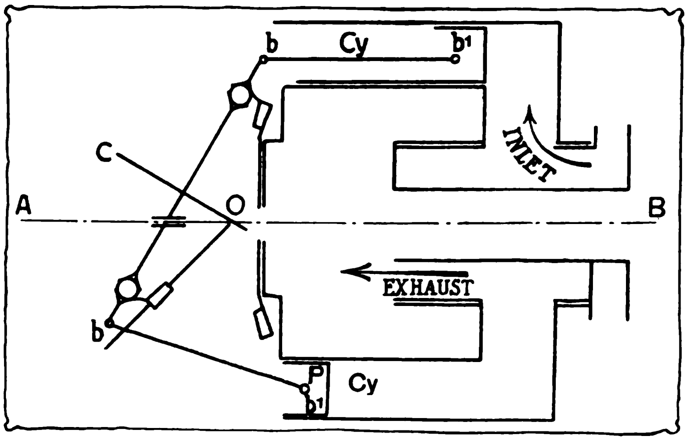

Fig. 1—Diagram of mechanical movement in one type of Canton-Unné motor

there are aluminum housings, and within each of these a round plate is secured obliquely upon the crankshaft which extends axially through the middle of the system. The connecting-rods are secured to these plates by means of a ball-bearing ring and suitable joints, so that the oblique disks are free to rotate, taking the crankshaft with them, while the cylinders remain stationary. The movement of one of the disks is diagrammatically represented in Fig. 1, showing two of the seven parallel cylinders, one at the beginning of the exhaust stroke and the other at the beginning of the power stroke. When the connecting rod b-b_1 of one of the pistons P is driven out against the circumferential ring of the disk, the latter can give room for the pistons only by rotating into the position in which its edge is farthest removed from the cylinder, and as the axis of the disk, CO, is at an angle with the crank shaft smaller than 45 degrees and the resistance to rotation is only that of friction with the ball-bearing ring—besides the load of the motor—the rotation is accomplished on the principle of following the lines of smallest resistance, practically in the same manner as a reversible worm drive is made possible by absorbing end-thrust in the ball-bearings of the worm. And a new impulsion to rotation is received as the rotating disk passes each successive cylinder of the seven, the charge being fired in each of them at that moment. Obversely, the rotation of the disk serves similarly to compress the charge in each cylinder while the disk is moving from the relative position to the cylinder indicated in the lower part of the diagram into the position shown in the upper part. The efficiency of the movement has been shown to be good when the frictions are minimized by the use of ball-bearings and by good lubrication.

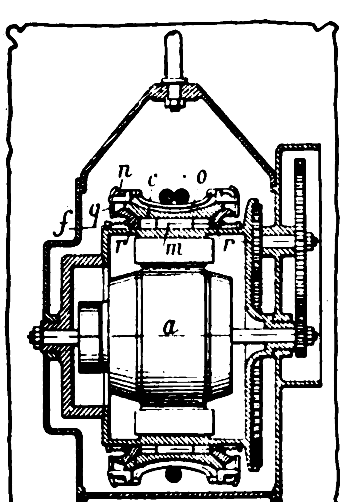

Fig. 2—Electric winch adapted for factory use

This motor develops 60 horsepower and weighs 110 kilograms. The bore and the stroke of each piston both measure 65 millimeters (2 3-5 inches), the construction naturally tending toward a short stroke in order to have the obliquity of the disks as small as possible for a given diameter of the whole system of cylinders. The valve control is arranged in the space separating the cylinders from the shaft. The water-cooling is operated by a centrifugal pump, the brass water jacket being secured upon the single casting in which the cylinders are bored. The front disk-casing contains a reducing gear; the rear one carries the magneto and incloses the force feed oil and the water pumps.—From *Allgemeine Automobil-Zeitung* of November 8 and *La Vie Automobile* of November 23.

—

ELECTRIC Winch.—The Wilhelmi electric winch is notable for its compactness and is suitable for use in connection with overhead cables for the transportation of material in factories which are electrically powered. It comprises essentially a small electric motor on the shaft of whose armature (a in Fig. 2) there is keyed a pinion which is in mesh with a gear mounted upon an intermediate shaft which is journaled in a bearing in the frame of the device. This intermediate shaft carries a second small pinion meshing with an internal gear wheel which is rigidly fixed upon the frame of the magnetic field, which arrangement renders it possible to offset the rotary speed of the armature by that of the field, so that the reduction effected by the gears need not be so large. The drum of the winch is a cast cylinder c mounted to revolve upon the rollers m which in turn roll freely upon the smoothly turned circumference of the field frame, and the drum can be locked to this frame by means of two cones r which are mounted upon the latter. The cones r are movable transversely, being held disengaged from the corresponding conical surfaces of the drum by the springs f but can be brought into engagement with the drum by means of the bell levers g whose upper arms are formed as cams and can be actuated by two small bell levers n, which are connected pairwise by flexible cross members o. As soon as a pull is applied to the free end of the cable which makes a turn and a half around the drum, and provided a load is attached to the other end of the cable, these cross-members o are depressed and, thereby being made to pull on levers n, cause the cones r to be engaged with the drum, so that the latter is revolved together with the cable in the direction which means the raising of the load. In order to stop the load it is sufficient to cease pulling at the free end of the cable or cord, as this has the effect of reducing the pressure upon the cross-members o and of permitting the springs f to separate the levers g and partly releasing the cone clutch. The movement of the winch also in itself tends constantly to cause a slack at the free end of the cable or cord.

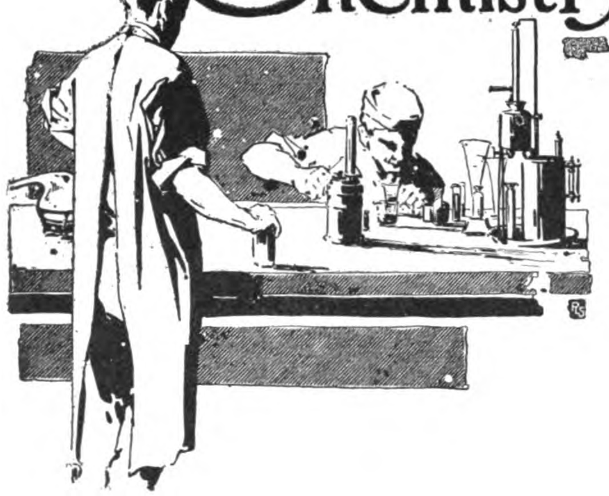
The operation of this winch is thus absolutely similar to that used in pulling a cord over a simple pulley, except in so far as the effort is concerned; to pull the load up, one pulls upon the cord, and to stop it one ceases to pull. A complete release of the cord causes a more complete disengagement of the cones r, and the load in that case draws the drum backward without causing the cord to slip on it.

The electric motor of this winch turns at a constant speed without interruption so long as the work with it is going on.—From *Zeitschrift des Vereines Deutscher Ingenieure*, October 5.

—

SQUARE Long-Stroke Motors.—According to Mr. Faroux, an opinion is "common among the Philistines" to the effect that it is the proportion between the bore and the stroke which makes a motor a long-stroke motor or a short-stroke motor. But in reality the length of the piston stroke is an absolute value, since on its measurement in inches depends the piston speed at any given number of revolutions. Up to a stroke length of 150 millimeters (6 inches) one cannot, with the present data of construction, speak of a long stroke. A motor with 70 millimeters bore and 120 millimeters stroke cannot be termed a long-stroke motor, despite the proportion of 1.7 between the stroke and the bore. And, on the other hand, a motor with bore and stroke both 160 millimeters is a long-stroke motor although it is commonly designated as "square." The proportion between bore and stroke is a matter of small interest, apart from statistics.—From *L'Auto*, November 10.

The Chemistry of Cylinder Oils



Professor Gallup Takes Issue with W. Jones Regarding Flash Point, Fire Point and Viscosity of Oils

WORCESTER, Mass.—Editor THE AUTOMOBILE:—The writer has noted with unusual interest the recent articles in THE AUTOMOBILE on the Chemistry of Cylinder Oils, by W. Jones, and inasmuch as the conclusions to be drawn from the statements made are so entirely at variance with not only common sense, but accepted practice, that some objection seems necessary.

The statements which deserve criticism are too numerous to mention in detail, since the space required would demand another article, but in general they may be referred to as:

1. Effect of flash point on the lubrictaing value of an oil.
2. Effect of fire point on the lubricating value of an oil.
3. Effect of viscosity point on the lubricating value of an oil.

Taking up 1: The chief argument in the article referred to seems to be that **in order to be effective, an oil should be of low flash and fire test, and for the specific reason that it burns up clean.** Might it be asked right here, what is the object of a lubricant? To lubricate or to furnish heat in the engine? If the latter be the case, why not dispense with the gasoline and use oil entirely? Or why not go still lower in flash and arrive at a point where combustion of the oil will be absolutely clean? **This would result in a clean engine and less gasoline would be used, since part of the power would be furnished by the oil itself.** But this is ridiculous. The best oil for lubrication is one which serves that purpose exclusively, one which will withstand the high speeds, high pressures and high temperatures without deterioration. At present there is no oil known which will satisfy the last condition perfectly, and the only alternative is to use that which approaches its accomplishment most nearly. Needless to say, the output of these oils is already controlled so that the distribution of a new oil requires a ready argument for its adoption, and the easiest one seems to be that it burns up quickly. Another feature of the low flash oil is that its price is usually lower than that of the high grade, and many users are appealed to on the ground that the expense for lubrication will be less. In answer to this, let it be pointed out that **an oil which is readily burned up requires excessive amounts to offset the loss due to the burning, so that at the end of a year it will be found that so much more of this low-price oil has been used than of the high-price best quality that the total cost is actually greater.** Also, consider the condition of the engine, something which is often lost sight of for the reason that an outward glance at it does not indicate the wear caused by a poor oil. It is a fact so well known as to be incontrovertible, and which has been proven in comparative tests, that the most efficient oiling is accomplished by the use of the highest flash test lubricant and in the smallest quantities possible, not by flooding the engine with a low test oil, the excess of which is burned up and which must be furnished to offset the low quality.

How long would the engine of a racing car stand up under the use of a low flash oil? The temperature existing in the cylinders under these conditions is so high that the use of an oil of low flash would amount to almost a negligible value, since the oil would be disintegrated before it had the chance to perform its function.

One more point: **The combustion of any oil is unclean;** the more unclean the larger the quantity, and hence the aim should be to use an oil which has the least tendency to burn, i.e., high flash.

Taking up the fire point, let it be remarked that this is of no value in the selection of an oil, since the lubricating qualities are determined by the flash point. This is true simply for the reason that the oil begins to disintegrate at the flash point and much of the lubricating value is lost in vaporization.

Under 3: **Viscosity is of prime importance,** if correctly determined, for the reason that it indicates whether an oil will be able to maintain a film at high temperatures or not. The usual standard of 70 degrees Fahrenheit is known to be misleading for the reason that many oils will show a high viscosity when tested at this temperature, but at higher temperatures, such as 212 degrees Fahrenheit, will show a marked decrease in this quality. This is more pronounced in the case of low flash test oils than high. Continued tests at still higher temperatures will show the divergence to be still more clearly defined. In other words, an oil showing a relatively high viscosity at low temperatures may be totally unfit for gas engine lubrication on account of the sudden loss in viscosity with increase of temperature. If, however, the test for viscosity is made at 212 degrees Fahrenheit, or at 250 degrees Fahrenheit, then the law becomes applicable and a high viscosity oil at this temperature should be given the selection. Investigating still further, it will be noted that these oils will have the higher flash tests. Put in another way, **an oil with a low flash test must possess a low viscosity at this temperature and therefore be unfit for lubrication even though at low temperature it possesses a high value of viscosity.**

On any modern engine of representative type and which is available, let a test be run for maximum horsepower, using a grade of oil outlined as advantageous by W. Jones, noting the quantity used, the heat going into the jacket water, and any other features which have a bearing on the question. Finally let an oil be used which is of high flash and of other characteristics similar to what is put forward in this letter and before an impartial set of judges, and if my position is not vindicated as to the latter being more efficient in dollars and cents regarding both the cost of oil used and wear on the engine, then an apology will be in order.—DAVID L. GALLUP, Assistant Professor of Gas Engineering, Worcester Polytechnic Institute.

Foreign Constructions Designs and Practices

The French School of Engineering

American Engineer Analyzes Features of French Designers and Makers—Fans Mounted in Radiators on Buses—Practically All Truck Tires Are of the Steel Type in Paris—How the Steel Bands Are Made

Part II

THE omnibus service in Paris is fairly good. The most striking innovation to be noticed at first glance is the appearance from the front. This is due to the use of a circular radiator with the fan within the same, much as in Fig. 1. Air is taken in through a screen at the front and is forced out radially through the peripheral interstices of the circular radiator unit. The fan diameter is about 16 inches and the space within the unit is adjusted accordingly. The radiator does excellent service. For upwards of a month, during hot weather, it was observed on buses, and the result may be summed up in the statement that one hot motor standing at the Gare du Nord on a very hot day was all that was noticed. The radiator was cool. The exhaust had the odor of excess gasoline. In addition to an apparent good efficiency, the radiators of this shape seem to be strong. Not one radiator was observed to be leaking. There is one other point: the spider in front which serves as the outboard bearing for the fan spindle serves also as an excellent protection for the radiator. A screw is placed inside of the spider through which the air is sifted. The fan blades are shaped to throw the air radially in the plane of the fan so that it passes out in the radial plane through the radiator unit.

Steel Truck Tires Numerous

In the commercial field revision is the order of the hour. Innovations of yesterday are the fractured hopes of today. The tire problem for trucks seems to be solved so far as Paris is concerned. The makers of tires seem to rejoice, for in the solving of the problem a way was found which makes it wholly unnecessary to call upon them to make good their frail guarantees. Fig. 2 shows how the tire problem was disposed of—steel tires are used. **Out of 100 heavy trucks actually loaded and going along the streets of Paris within a single week in July, 98 were steel shod on all four wheels.** One truck was fitted with steel rear and solid rubber front tires, and the remaining truck, about 2½-ton size, was equipped with pneumatics.

Of the steel shoes actually used on trucks in Paris all are not as illustrated in Fig. 2. Indeed, there is a wide diversity of sizes, but as a rule the front tires are as wide or wider than the rear tires. Fig. 2A shows a sixteen-spoke wooden wheel with a wooden felloe, fitted with a steel band slightly over 7 inches wide, made of tire-steel slightly over 1⅛ inch thick. The front wheel, Fig. 2B, has two bands with serrated surfaces diagonally disposed, with the grooves running right-hand on one band and left-hand on the other. The two bands, as they appear on the wheels, look very much like a pair of monster right and left-hand milling-cutters on an arbor. Each band on the front wheel was about 4½ inches wide. The space between the bands was about ¾ inch wide.

The idea seems to be to prevent skidding at the front and

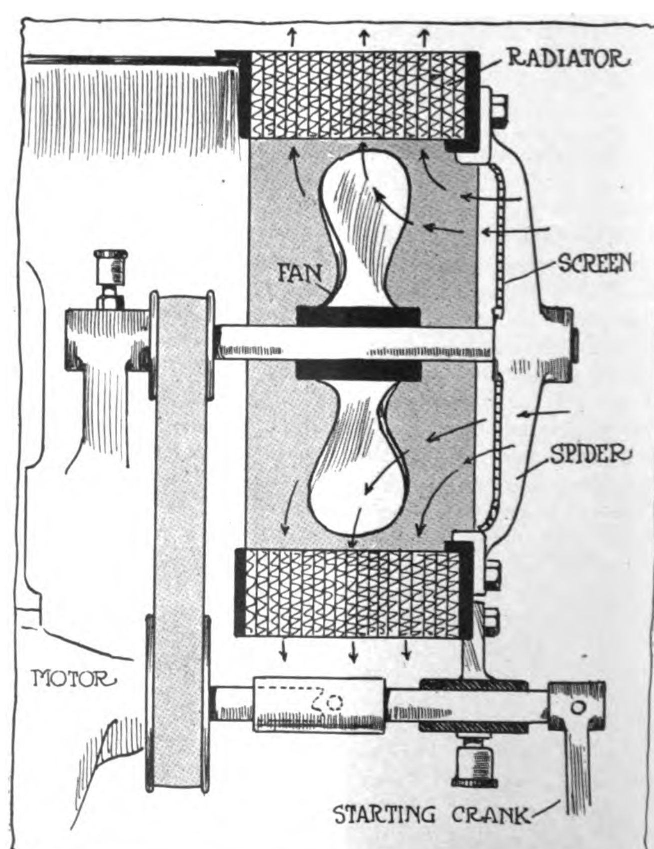


Fig. 1—Style of radiator used on Paris buses with air propeller located within the radiator and provided with an outboard bearing

to gain traction at the rear. The performance of a truck fitted with these steel bands was excellent. On one occasion, in a stone yard on the bank of the Seine, the truck, heavily loaded, went up a deep dirt road to the paved street beyond without any difficulty. On several occasions, on wet pavement, observation showed good performance of these trucks.

There is one point involved in this matter of steel-shod road wheels which should not be overlooked. The chassis springs are long of span, made of wide, thin plates, and the rear springs are, in the majority of cases, of the platform type.

Wide Steel Tires on Rear Wheels

Some trucks have wide steel tires on the rear wheels. Even widths of 12 inches are in use. In a few cases the steel bands on rear wheels are between 4 and 5 inches. It will be fair to conclude that there is no standard of width in sight as yet. The wheels, in the main, are 36 inches in diameter; a few are greater in diameter, some are less.

It might be said that steel bands are prone to leave the mechanisms of the vehicle unprotected against shock and vibration. One fellow said when this subject was broached, "There is nothing so shocking as a large tire bill!" At all events, the steel bands are not giving out; they have not been used long enough to make it possible to know how many years they will survive if they are properly set and if the service is fair. In making observation, the casualty list so far for trucks shows one truck disabled and being towed in —that truck was fitted with solid rubber tires!

Of course, there are commercial vehicles in service fitted with solid rubber tires and even pneumatics are employed to a certain extent, but these trucks are doing soft work. The army uses solids and pneumatics for hospital and like duties. The buses in Paris are fitted with solid rubber bands. Newspaper and post-office service fall into the same category. But real trucking work, where the loads are heavy, is being done in Paris on steel-shod wheels. The speeds of these trucks range between 7 and 11 miles per hour, depending upon the sizes of the trucks. The heavier trucks go slower than the lighter trucks, of course.

Making Steel Bands for Truck Wheels

IN France where automobile trucks are being operated, running on steel feet, displacing solid rubber tires, it is interesting to note that the steel bands are more carefully made than they were in the past, as they were used on the wheels of horse-drawn trucks. In addition to a greater width of bands, and a considerably increased thickness of the metal of the bands, **the important advance is settled in the point that welding is not resorted to, primarily on account of the lack of average ability of welds; furthermore, due to the use of a superior grade of steel; metal that is incapable of being welded.**

It is not unusual to note in this newer work the use of bands up to 12 inches in width. Some of these bands have a radial thickness of wall of 2 inches. As a rule the steel bands are considerably wider than the felloes over which the bands are pressed. The band over-hang is as much as 2 inches on each side of the felloe. In putting these steel bands on the felloes, remembering that the special grade of steel used in them would be damaged by heating the bands in order to make a shrink fit, they are set by a pressing process, but, instead of being pressed on in the ordinary way, they are kneaded while they are being pressed on. In a word, by means of a plurality of hydraulic press-units mounted in a cast-iron frame with the units spaced equally around the periphery of the steel band to be pressed on, pressure is exerted radially, and this series of operations is conducted while the main press is forcing the steel band over the wooden felloe, into the position it will occupy in service.

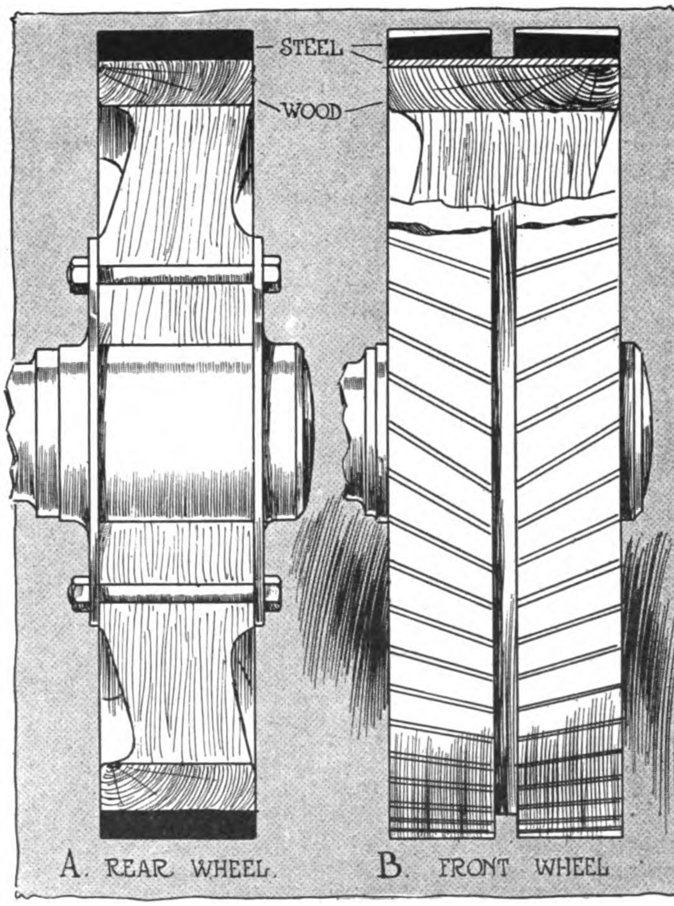

Fig. 2—A, truck rear wheel with sixteen spokes and fitted with steel band instead of rubber tire. B, front wheel of the same truck having a pair of bands with serrated faces, with serrations placed diagonally and reversed.

Speaking of the quality of the steel, it combines hardness with toughness. The hardness is due to the proper admixture of carbon, mingled with silicon and manganese. An acid steel is preferred. As to the process of production, if the ores are Swedish iron, or blends of other ores of suitable analysis, it is not so important to adhere to the acid process. The toughness of the steel is partly traced to the process; partly to the ores and their excellent characteristics, but, in the main, to the analysis which shows a mere trace of sulphur and phosphorus, not forgetting that, in the forming of the tires the metal is worked under the most favorable conditions for the birth of a fine grain and the kneading of fiber.

The billets, instead of being of the usual shape, are round and of the required thickness to furnish enough metal for one band. Instead of rolling or hammering the billets, they are first, after heating to the desired temperature, subjected to the pressure applied to the end of a mandrel which makes a hole in the center of the billet. A second mandrel adds to the size of the hole. A third, and a fourth, help in the process of enlarging the central hole. In the course of the process the hole becomes large enough so that the expanded metal forms a ring. This ring is placed in a rolling machine and, by means of rollers, the metal is subjected to pressure, and the ring is slowly but surely formed into a band, always under the condition of temperature which is likely to give birth to fine grain, and it is to the rolling process under these conditions that fiber is woven out of the fine grain. The rolled product is in the shape of the rough band near size; finishing on a lathe brings the band down to size for use on the wheel. It has been found in actual service in France, that bands, so made, last for more than 60,000 miles on heavy trucks. The cost of a set of these bands is about $200.

Part III Carburetion

by Robert W. A. Brewer

Subject Digest

One of the most important functions of the carbureter is to regulate the amount of fuel passing through the jet in a unit of time.

Under certain conditions where heat is not available an excess of fuel is necessary to make up the required quantity of vaporized gas.

A factor which comes into play and is of great importance is the variation in viscosity of the fuel due to the changes in the temperature.

Another point which must be carefully noted is the fact that although a greater volume of fuel is taken through the jet at a higher temperature, still the actual weight per unit volume of the fuel is reduced.

There are two methods of meeting and adjusting for the varying fuel conditions. One is by a variable orifice and the other by an obstruction in the fuel line at some point before the fuel mixes with the air.

Spring-actuated devices are not needed in scientifically designed carbureters and are rapidly disappearing for this reason.

A CARBURETER **jet has two functions to perform, first, that of spraying the fuel into the mixing chamber, and second, that of regulating the amount of fuel passing through the carbureter in unit time.** We have already dealt with the question of spraying and we will now proceed to discuss how different heights and forms of jets can be designed and arranged to carry out the measuring operations. Going back in history, we remember that the jet carbureter was originally unknown, as the surface carbureter was not provided with a jet, and it was with the advent of the Maybach instrument that the jet came into use and is now almost universally adopted.

During the development of the jet carbureter it was generally the custom to utilize a small brass nipple with a single hole, and the amount of fuel which issued from this orifice was controlled by the difference of pressure existing between the jet chamber and the float chamber of the carbureter.

Assuming that an engine is running at more or less constant speed, the simplest form of carbureter consists of a single jet located in the throat of a venturi tube, and the size of the orifice can then be calculated from experimental data so as to correctly proportion the efflux of the fuel to the amount of air passing.

Reverting to the second article, published last week, it will be borne in mind that under certain conditions at the time of starting up **when heat is not available it is essential that there should be an excess of fuel passing through the jet.** This state of affairs is also advisable for slow-running conditions when the air passing is not entirely concentrated round the jet and there is consequently a lack of mechanical action.

When the engine speed is increased the fuel-flow curve (as plotted, showing the relation between fuel discharge and air velocity) takes an upward trend so that at the higher air velocities the amount of fuel flowing is greater than it should be to give a correct proportioning of the mixture. At the same time the amount of air flowing is in a falling ratio. In other words, **the air curve droops while the fuel curve rises.** It is necessary, therefore, to take certain precautions so that this tendency can be overcome, and we, therefore, find that modern carburter development has been concentrated, to a great extent, upon dealing with this particular matter.

There is another factor which also comes into play, namely, **the viscosity of the fuel which is a function of its temperature.** I have shown from time to time how that Rummel's formula for the rate of fuel discharged from a jet applies.

$$C_1\left(\frac{Q}{t}\right)^2 + C_2\left(\frac{Q}{t}\right) = h$$

where C_1 and C_2 are constants, being the co-efficient of discharge for the orifice.

In previous tests which I have made to find out the value of C for gasoline jets of the dimensions ordinarily in use, working from the formula generally used in such cases.

$$Q = C\omega\sqrt{2gh}$$

where Q is the discharge in cubic centimeters per second,
c is the co-efficient of the discharge,
ω is the area of the orifice in square centimeters,
g is the acceleration due to gravity in centimeters per second,
h is the head in centimeters over the orifice.

I have found from numerous experiments with jets whose lengths were approximately five times their diameter that the co-efficient of discharge of gasoline at a temperature of 60 degrees Fahrenheit varied from 0.738 to 0.770, the mean co-efficient being 0.7. Unwin gives 0.77 as that for water in his Treatise on Hydraulics.

Now this feature gives the designer some scope for retarding the flow of fuel at high speed, and it has been taken advantage of in some instruments by interposing a resisting medium in the fuel path. **In other cases an obstruction has been placed immediately outside the jet orifice so as to throw back the issuing stream upon the orifice.** I have found from experiment that a discharge from such an orifice is considerably affected by particles of fuel dropping back, but it is a difficult matter to form any law upon this subject.

There is one other important thing to be borne in mind, namely, **the effect of temperature upon viscosity, and at the same time upon its specific gravity.** One can see that although a greater quantity of fuel with a reduced viscosity passes through a given orifice in unit time, yet the actual weight of that fuel is also reduced but by a lesser proportion on account of its rise of temperature.

Passing now from the fixed-jet and variable suction instrument we will go on to the varying-jet and constant-suction type. This type has been evolved in order to overcome the difficulties referred to at high speeds, and **it appears in at least two types, those where the orifice is varied in dimensions where the fuel meets the air stream, and those where this adjustment takes place at some point in the fuel line before the fuel actually leaves its passage to mix with the air.**

In the latter type of instrument there may be some difficulty on account of the wear of the moving parts exposed to the air stream, but this is to some extent counter-balanced by the increased spraying effect due to the arrangement. On the other hand, with the submerged type of metering pin the conditions are reversed.

When one comes to consider a varying orifice of this type scientifically, one is up against a problem of some importance and difficulty, for we find that **with a pin of straight taper the increase in the area of the orifice is not proportional to the movement of the pin.** Furthermore, we find that **as the pin is gradually withdrawn from the orifice the ratio of the length of the orifice to its effective area varies from moment to moment.**

There is still another difficulty which I have found, due to the metering pin not always lying central in the hole, and I am of belief that it is for this reason that one often experiences erratic behavior in this type of instrument. For instance, I have found that with an increasing area of from 1.02 square milimeters to 3.10 square milimeters, the co-efficient of discharge varies from 0.783 to 0.500. In another case where the areas were smaller the co-efficient of discharge rose from 0.415 to 0.790 as the effective area increased. In another case with an engine on trial at 500 revolutions per minute giving 8.25 boiler horsepower, the co-efficient was 0.795; at 1,000 revolutions per minute giving 19 boiler horsepower it was 0.568, and at 1,800 revolutions per minute giving 26 boiler horsepower the co-efficient fell to 0.482.

In order to get over this difficulty I have designed a carbureter combining the characteristics of the two types before mentioned, and **with such a combination it is possible to obtain any desired results with regard to air and fuel flow.** Furthermore, such an instrument can be adjusted within certain limits so as to surmount the difficulty of the **fixed-fuel flow at starting.**

The multiple jet of the Polyrhoe has many features to recommend it in respect to the accuracy of the jets, as we all know how difficult it is to make small jets with sufficient acccuracy, and as a further expansion of this type there is the jet in the form of a narrow adjustable slit in the Ideal carbureter.

Here we have an instrument with a right-angled movement in which as the air valve opens it uncovers a shutter over the gasoline orifice, so that when the carbureter works at its predetermined depression the efflux of fuel from each unit length of the slit is the same, neglecting, of course, the friction at the ends of the slit. Widening the slit by means of an adjusting screw gives a uniform proportional increase of fuel flow throughout the range of working.

In the Polyrhoe, the action is to reduce the width of the air slit, but the result is the same in each case.

There is one ruling factor which has to be observed in all these types of instruments, and that is the gradual action of the free moving parts. A free moving part is often condemned because it works badly, and it can only be made satisfactory by accurate workmanship and a suitable dashpot. The expense of carbureter manufacture is generally a function of the accuracy of workmanship, and for this reason I have endeavored to eliminate accurate workmanship of importance from my new design.

It is unfortunately a fact that a large number of wasters are made in modern high-class carbureters on account of the lack of extreme accuracy and exact clearances, and for American practice, particularly where large output is concerned, there should not be too great a dependence upon accuracy of manufacture.

The Holley carbureter undoubtedly scores by its absence of moving parts which either would require accurate machining or careful adjustment. Too much dependence must not be placed upon adjustments of spring-actuated devices. These are fortunately rapidly disappearing, as in scientific designs they are not necessary. **Our present knowledge enables us to design rather than to compromise in carbureter work.**

When the Carbureter Is Wrongfully Blamed

THE most abused part of a motor is the carbureter. Perhaps it is something which has been handed down to us from the early days of automobiling that leads us to grab a wrench and start for the carbureter whenever the motor misfires, overheats, carbonizes or does any of the hundred and one things that a balky gasoline motor can and does do.

One of the most common things that a carbureter is blamed for is the failure of the motor to throttle down. One man complains that he cannot get his car to run any slower than 10 miles an hour on high speed. He states that he is tired of trying to improve his trouble and that whenever he changes the adjustments things become worse instead of better. **He forgets his spark-plugs and the fact that after a time they become sooted or the electrodes become farther apart on account of the heavy work they are called upon to perform during a hard season of automobiling.** If he will close up the gaps on his plugs he will probably be able to throttle down to 5 miles an hour without trouble on high gear. The spark-plugs should not have their gaps further than .02 inch apart when running on the magneto, as is habitually done in most cases. The magneto that is turned over at the same speed as the motor does not generate as high a current when the motor is running at 200 revolutions per minute as it does when the motor is running at 1,000 revolutions. Naturally **the current is not strong enough at low speeds to jump the increased gap, and as a result there is an irregularity in the running of the car when the speed drops to the point where the spark does not occur.**

Another man, whose motor is continually fouling even after he has cut down his mixture until it is as thin as possible, forgets that he is using a bad oil in his effort to make his running inexpensive. Even a little bad oil can carbonize badly. It does not take an over-supply. It is a fallacy to try to save money on oil. The best is none too good for the automobile engine. After the carbureter has been adjusted so that the car runs smoothly it is seldom that it has to be changed unless to meet a decided change in climatic conditions.

Overheating may be due to too rich a mixture, but the water circulating system should come in for its share of suspicion. Not long ago an enthusiastic automobilist whose car was overheating discarded a perfectly good carbureter because of this trouble. He was greatly elated because he had received what he thought to be a handsome allowance for the carbureter which had formerly been upon the motor and which he thought to be out of commission. After the smoke cleared away he had bought another carbureter of the same make he formerly had used and another water pump to take the place of the corroded article he had been depending upon. Besides this he had adjusted the fan belt which the garage man had told him was slipping badly and promoting the overheating process.

Smoke due to an over-supply of oil is sometimes blamed upon the carbureter. **Oil smoke is bluish in tinge, while carburetor smoke is a black or dak gray.**

Continual tampering with the carbureter leads nowhere. It is necessary that adjustments be made systematically.

System of New York Splitdorf Service Plant

Gotham Department of Magneto Manufacturer Organized to Give Users of Splitdorf Products Prompt Service

A PENNY saved is a penny earned. In these seven words lies the abstract of commercial wisdom of the past 40 centuries which a few years ago became the foundation of a very important economic idea, that of scientific management. The principle of scientific management is the elimination of futile effort and of waste of material, to which factors is due the high production cost of manufactured articles. Carefully organized and systematically conducted experiments have shown that even with so-called ideal installations in factories and shops half of the power and labor consumed goes to waste, that is, it is expended without the production of a result or value. In other words, an efficiency of only 50 per cent. is obtained from the power and labor expended.

High efficiency is to be desired by everybody. No one wishes to pay for more than he receives, and this progressive turn of mind is at the bottom of all economic and social problems. The proposition remains the same whether the parties are called buyer and seller, employer and employee, or what not. Every one objects with equal vigor to the high cost of living, to extortion by buccaneering garage men and to all the other nuisances of modern life.

The automobile owner today recognizes that when he buys an automobile, he may expect a certain amount of service from it, for a reasonable cost of upkeep. He also knows that if anything goes wrong with the car, even through his own fault, he is entitled to a good repair job done at a comparatively low price. He demands from the maker of the car every protection conceivable against the outrageous charges of the old-time repair man.

Service Needed for Accessories

The same applies to the parts of every car of good make. The fact that a car manufacturer buys carbureters, ignition or lighting systems from a special maker of such accessories does not alter the condition that he must be ready to give efficient and economical service to the users of his products, when these respective accessories are in need of repair. In the case of large accessory manufacturers, the latter are beginning to organize their own service departments, thereby taking a great deal of work off the car maker, to whose lot it would otherwise fall. In this respect, magneto manufacturers are making especially energetic efforts to serve the users of their products promptly and at the lowest possible charge.

One of the most recent undertakings along this line is the central service department of the Splitdorf Electrical Company, 18-20 West Sixty-third street, New York City. This department is organized in a way like an automobile service department, the principal points of the business and its operating system being given below.

The service department occupies the ground floor and basement of the address mentioned. Office, retail salesroom and shop are located on the ground floor, while the basement contains a machine shop and garage room, in which latter magnetos and lighting systems are installed on cars. Furthermore, stockroom and shipping department are located in the basement. The number of men employed in these practical departments, outside the sales and office rooms, is twenty-seven.

Splitdorf System Has Four Forms

Due to the fact that it has to deal only with products of a very few classes, the system used by the Splitdorf company is rather simple, yet elaborate enough to permit of recording every essential detail of the service work done by the company. The purpose, to which this system is adapted, is twofold: first, it is a means of controlling the activities of the workers in general and of seeing whether all the necessary repair work is being done; second, it affords exact records of the repair costs and permits of placing the minimum charge on every job which is done in the establishment. Thus the system works out to the advantage of both the company and the user of the company's products.

The system itself depends for its execution upon a number of blanks which are handled by the company's employees as the work passes through their hands. Four forms, which are printed on three cards, are all that are used. Figs. 2 and 3 are repair orders, Fig. 4, being the reverse of Fig. 3, is a repair cost form, while Fig. 1 is the stockroom inventory card used to keep track of materials.

Repair work, which constitutes the bulk of the activity of the Sixty-third street place, is handled in the following manner. When a magneto, coil, etc., is received, a form is filled out which accompanies the accessory through the service department while it is being worked upon there. An entry is also made in a book.

Fig. 1—Stockroom record card used in the New York service department of the Splitdorf Electrical Company. Fig. 2—Repair order card used in the Splitdorf service department when repair jobs are received by express

Then the accessory is sent into the shop where all the necessary repairs and replacements are made. The work being done, the finished product is either sent to the owner or held for delivery, depending on circumstances. The working orders which accompany the objects to be repaired on their way through the shop are printed on their reverse sides for recording the cost of the work. These cost records are used as a basis for the bill delivered with the finished repair.

Taking up these several operations in turn, attention must be called to the fact that accessories brought into the office of the department by their owners are sent through the shop equipped with a different repair card than the goods which arrive from out-of-town by express. Fig. 3 shows the card which is filled out in the first case, Fig. 2 that used in the second. Name and address of the owner, as well as of details relating to the magneto or coil and the repairs necessary on it, are entered on either card, whatever one is used. If the magneto is brought into the place by the owner, Fig. 3 is made out, the stub at the bottom, which is detached and delivered to the owner, serving as a receipt. In the case of accessories arriving by express, no receipt except an acknowledgment per letter is used.

Whenever a device is received by the Splitdorf company and a repair work order is made out, the accessory is entered in a record book under the reference or job number. Two separate books and, consequently, separate series of job numbers are used for the articles arriving by express and delivered by the owner himself. No numbers of one series duplicate those of the other series. Incidentally, it should be noted that the repair orders for magnetos and coils received from out-of-town are blue, while the form, Fig. 3, is tan.

These forms being filled out the magneto—we will speak of magnetos only, to avoid unnecessary complication—is immediately delivered into the shop. Here work is started on it at once. This expedition is made possible by the distribution of work in the shop, where every man works on just one sort of work. The magneto is first turned over to a man on the first bench, who completely disassembles it and puts the parts in a box, which is moved along the bench. The foreman goes over the parts, sees what repairs are needed and either writes instructions on the card, or gives them to the workers who do the specific repairs. In this way, the owner is often saved the expense of a new part by a minor repair. The parts are then repaired or replaced, as ordered by the foreman, after which the magneto is assembled again, inspected and tested for the perfect operation of its various parts. The man who made the repair then fills out the back of the repair order, which is printed as Fig. 4. Materials used are reported on this blank, and so is the time used in repairing the magneto. The charges for material and labor are entered on the card in the office, and the bill is made out from them, being delivered to the customer with his magneto.

When a repair is completed, the magneto is put into the storeroom and is there placed in a compartment by itself and held until the owner calls for it, if he had brought it in himself. If the magneto had arrived by express, it is returned to the owner as soon as the repair is done.

The stockroom of the service department, in connection with which the New York retail store is operated, contains both complete magneto, coil and lighting assemblies and all the parts of the same. These articles are numbered, according to the company's factory drawings, and are kept in orderly arranged shelves. To keep track of them, a record card is used for every type and size of part, and these cards are kept alphabetically according to the names of the articles. The inventory file card, Fig. 1, is so designed that whenever any quantity of a part is received, it is entered on the card, together with the date it arrives. Likewise, outgoing material is recorded on this card, and a monthly balance is made which affords a clear review of the stockroom and its business. The records of incoming material are checked against the bills of lading and the factory invoices, while the outgoing material must correspond to the material records appearing on the backs of the repair orders.

The labor charges on the repair work orders must, on the other hand, total up the sum of working time recorded by the clock cards of the shop workers. This phase of the subject, which has been repeatedly treated in The Automobile, does not require to be taken up again in this article.

One interesting point of this system is that, unlike other recording systems, it does not call for the services of any men specially occupied with its execution. The store clerks receive the incoming magnetos, coils and so forth, and sign for them if they arrive by express, or make out a repair order with a receipt stub when the accessories are brought in by their owners. From the orders complementary to express shipments the blue cards, Fig. 2, are made out, which, like the cards, Fig. 3, serve as permanent record accompanying the devices through the shop and as blanks for the cost records, from which the bills are made out. The latter work is done by a bookkeeper or office clerk, and is ordinary office work really outside of the special service system. To put the whole situation in a nut shell, the system is carried out by the entire force employed in the establishment, thereby relieving the individuals of any great measure of connection with it. This makes the whole system so much easier to enforce, as with the work the responsibility is shared among the workers. Consequently, the chance of an error is also materially reduced, as every record form passes through several hands, whereby the probability of its being found out is greatly enhanced. Thereby one of the principal aims of efficient management is realized.

Placing Truck Back on Road—Selden Patents Not Now in Effect—Motor Can Be Used as Air Compressor—Trouble Traced to the Spark-Plugs—Carelessness Responsible for Clutch Trouble—Origin of Venturi—Motor Overheats

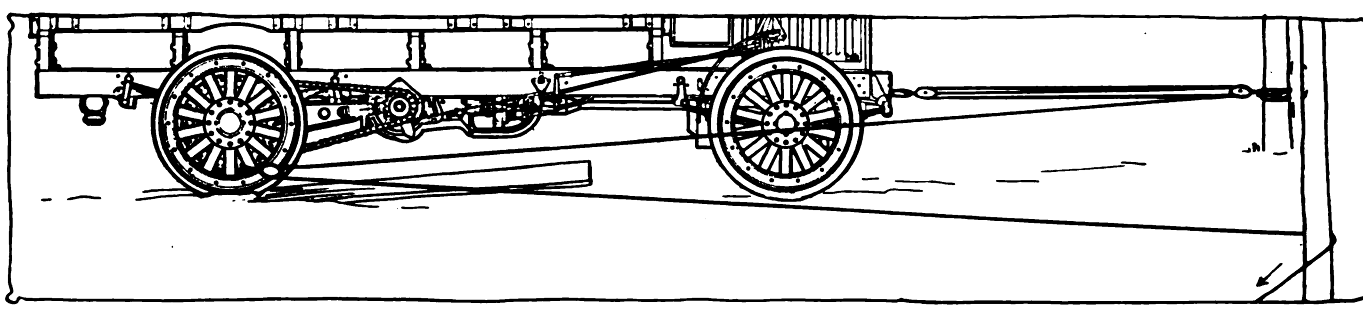

Fig. 1—One way of using block and tackle to move stranded truck by its own power

Putting Truck Back on Road

EDITOR THE AUTOMOBILE:—In case a 1-ton truck slides off the road into soft ground, is there a way of putting the truck back on the road with a block and fall under its own power?

Jersey City, N. J. CHARLES NEU.

—This is a case where the particular circumstances surrounding the truck and its position are of the utmost importance. A block and fall could be rigged up in such a way that it would exert a pull on the truck and would move it a short distance and then after rearranging the apparatus another distance gained until the truck was once more upon hard ground, if the conditions were right, while under other circumstances it would be impossible to apply the block and fall.

Assuming that the truck were in some position where the block and fall could be used to pull it out a little distance at a time, it would be necessary in the first place, assuming that the wheels spun around without securing traction, to stop the differential action by locking one of the wheels so that it could not revolve. It could be roped in place. The block and fall could then be attached as shown in Fig. 1. The tackle is attached to a tree or post and to the front or rear of the truck, depending upon the direction in which it is to be pulled. The loose rope is then secured through the means of another block to the rear wheel and the end of the rope passed around a tree to hold whatever advantage is gained when the motor is started. A plank is then placed in front of the wheel in such a way that a slight forward movement of the truck will bring the wheel up on the plank and put it in a position to secure traction.

A far better way of getting out of soft ground than by using a block and fall is to put a plank under each rear wheel as far as it will go. The plank is then tied to the wheel in the manner shown in Fig. 2. When the wheels start to revolve they will carry the plank under the wheel with them and the result will be that traction is automatically given.

A chain-fall could be rigged up if the truck is at some place where the fall could be attached. Very often also the shovel can be plied with good effect or a chain wrapped around the wheel to form a mudhook. If the wheels will not revolve the chains should be discontinued.

Selden Patents Now Expired

Editor THE AUTOMOBILE:—Will you kindly answer the following in your next issue of THE AUTOMOBILE?

Can anyone build an automobile to order for a customer without infringing on the Selden patents? This person would no doubt continue to build a few machines for different people wherein he would place the best parts of their kind on the market today. I am sure that there would be trouble for him in regard to the above named patents. If the patents are still in force kindly let me know, and the length of time they can still be in force.

Newark, N. J. A STEADY READER.

—As far as the Selden patents are concerned there need be no fear, as they have now expired. The only thing you will have to guard against will be the installation of other patented devices which are, to say the least, rather numerous in automobile construction. By using standard parts and devices, however, no harm can be done, even in this direction.

Small Motor as Air Compressor

Editor THE AUTOMOBILE:—I have a small marine type gasoline engine which I wish to convert into an air compressor for charging a storage tank for garage use at maximum pressure of 150-200 pounds. The engine is 3 inches by 3 inches; rings fit tightly and everything is in good working order. Water-cooled.

Please advise me of the best way to make the change.

Can you give me the address of the Waterhouse Welding Company?

Prattsburgh, N. Y. H. G. MORGAN.

—You do not mention the type of construction of the motor or if it is a two- or four-cycle. The principles would be the same however in any case. Assuming that it is a two-cycle motor all that would be necessary would be to cut down the compression space until there is nothing left but just enough for piston clearance, say 1-8 inch. An outlet pipe with a ball check is then installed, the check operating, of course, so that the air does not escape from the tank back into the motor? In the case of a four-cycle motor the only difference would be that besides cutting down the compression space to practically nothing, the exhaust valve will have to be locked and the intake valve made to act automatically. That is the cam action should be removed and a spring installed which will be just light enough for the piston to draw up on its suction stroke. It will then act automatically. A safety valve loaded to the desired pressure could be put on the tank or a gauge installed which could be watched while the power is on.

Users of Air Starting Systems

Editor THE AUTOMOBILE:—Which 1912 and 1913 model automobiles are using compressed air starters?

Jamestown, N. Y. J. E. WHITE.

—Among the prominent users of air starting devices for the season of 1912 were the Winton, Chalmers, Parry, McFarlan, Austin, Amplex, Berkshire, Midland and Nance. The makers have not all fully determined on their 1913 starters as yet, although it may be stated that the trend is toward electricity and acetylene. The above will probably continue with the air starters for 1913.

Pounds When Running Slowly

Editor THE AUTOMOBILE:—I have a four-cylinder, four-cycle Cadillac. When running slowly the fourth cylinder misses. It does not fire at all as it should; it does not pick up quickly when changing for higher speed but seems to be all right when running rapidly. It will start pounding when running slowly, the cylinders soot up quite badly and so do the spark-plugs in the fourth cylinder. I have a high-tension magneto of the Bosch make. Some think it is in this and others tell me to use a different spark-plug. Do you suppose it could be in the piston rings? Would like to hear from you about the trouble through Letters Answered and Discussed.

Petoskem, Mich. J. OLDHAM.

—Your trouble is either due to bad carbureter adjustment, a leaky bushing around the intake valve, improper spark gap or a combination of these. Try a little richer mixture on low speed and renew the bushing surrounding the inlet valve stem on the number four cylinder. The latter trouble is very common and often unsuspected as there is no perceptible hiss as is the case with other gas leaks. Air is sucked into the cylinder around the leaky bushing and the result is a lean mixture in the affected cylinder. The spark gap on a magneto ignition system should be about .02 inch. On the battery system the gap can be as large as .045 inch with satisfactory results. Close up the gaps of the plugs and adjust the carbureter before renewing the bushing so that in case the latter is in good condition you will not have had the expense of fitting a new one unnecessarily.

Origin of the Venturi Tube

Editor THE AUTOMOBILE:—Will you kindly tell me through your columns the origin of the name Venturi tube now frequently mentioned in carbureter construction. What was its original form and application?

Penaski, N. Y. J. H. D.

—The origin of the Venturi is traced to G. B. Venturi, an Italian physicist, who lived between the years of 1746 and 1822. The purpose of the tube was to reduce the resistance to air flow. In Venturi's explanation of the tube, 1791, he states that the quantity of air that would pass through in a given time under a given depression would be multiplied by four as compared to a plain tube, provided the two inverted cone frustrums of which it was composed could be so arranged that the convergent angle of one of the cones was fixed at 30 degrees while the divergent angle of the other was fixed at 7 degrees. The designs of the Venturi used in carbureter work vary materially from the designers' dimensions, as practice does not render the latter feasible.

Did Not Lubricate His Clutch

Editor THE AUTOMOBILE:—I am having some trouble with the clutch of my model R, 1910 Reo touring car and although I have had an expert take same apart and thoroughly cleanse the plates he has been unable to do anything for me. The trouble is as follows:

Instead of being able to start the car gently and with increasing speed by gradually releasing my foot from the pedal nothing happens until the pedal is almost all the way up, and then the car starts with a jerk, often killing the engine, and is naturally very hard on the transmission and driving gears in the rear axle, not to speak of the wear on tires. Experts and Reo owners have frequently told me to wash the clutch plates out by squirting in gasoline through the plug hole for that purpose. This I have frequently done, sometimes squirting 1 gallon of gasoline through this hole. This does not do any good but I find that by putting in about one teaspoonful of fairly thin sewing machine oil it cures the trouble for two or three days, when the clutch will again become fierce. Another trouble is as follows:

On the pressing of the clutch pedal the clutch does not seem to properly disengage and instead of the driving shaft between the clutch and the transmission box ceasing to revolve when the pedal is depressed it rotates at practically the same speed as before, the consequence being that when the gear-shifting lever is moved in any desired position either to start or change speeds, a horrible grinding noise is the result, caused, of course, by the gears revolving so rapidly that they will not mesh until their motion is stopped, when of course they will mesh.

It is a most uncomfortable feeling, as I am always in fear of stripping the gearset or breaking some part of the driving mechanism in the rear axle, and if there is any remedy for this I would be glad if you would kindly advise me. I am confident that the plates in the multiple-disk clutch are perfectly clean and therefore the trouble is not caused by any dirt or foreign matter between the disks. I have never put any oil in the clutch except as above described, as I always understood that this type of clutch was supposed to be run dry.

Macleod, Ont. R. H. HILLIARD.

—The trouble has developed because you have not lubricated your clutch. The proper oil to use in the Reo 1910 clutch is a mixture of kerosene and medium cylinder oil in about equal pro-

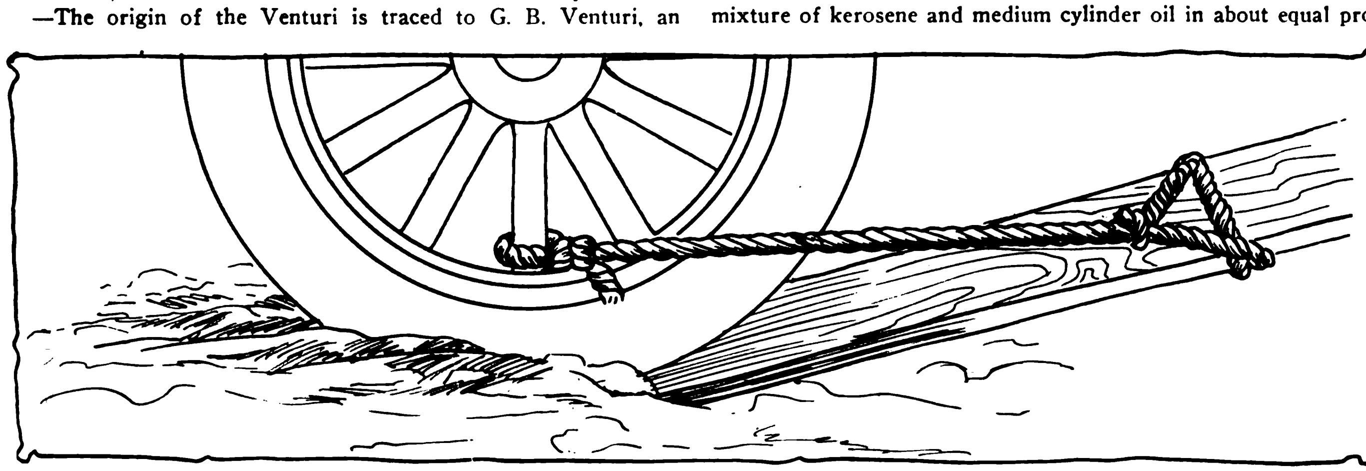

Fig. 2—Scheme sometimes employed for moving truck which has gone off road into soft ground

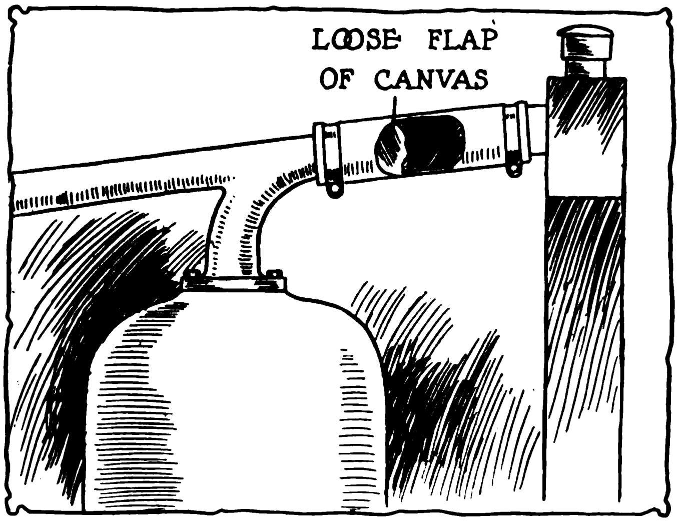

Fig. 3—Where overheating trouble sometimes lies unsuspected

portions. The Reo 1910 clutch gave trouble in some respects and it has been entirely redesigned, heavier plates lined with asbestos fabric new being fitted. A view of this clutch is shown in Fig. 4. The plates in the 1910 Reo gave trouble by their liability to distortion, especially when they had been insufficiently lubricated and this is the cause of your trouble. New plates will be necessary. It is possible that the 1912 type of plates could be fitted to your car without much expense. This matter should be taken up with the factory. Another part which is probably worn is the clutch guide bushing which surrounds the end of the crankshaft. The bushing should be carefully examined and, if worn, renewed.

Sudden Case of Overheating

Editor The Automobile:—Will you kindly give me a little information? I have a 1910 Oakland car which for the past season has been overheating very badly. The trouble started all at once. On Saturday the car was working splendidly on the worst hills in Vermont. On Monday it would get hot in running 3 miles, regardless of what oil or mixture of gas was used, and continued to work that way since. The richer the mixture the cooler the car would work, but with a decided slump in power.

2—I have had to replace the pinion shaft and tube on account of a broken roller bearing. The large differential gear is sadly worn. If I set the pinion so that the noise is at a minimum the car works hard. If I mesh it deeper it growls badly but will work much easier. Would you advise a new gear and will you kindly tell me how I can be certain that the pinion and gear are meshed properly? Could a worn gear cause a car to work hard enough to overheat?

Brasher Falls, N. Y. P. E. Kennehan.

—The trouble is either due to carbon trouble or an obstruction in the cooling system. First, have the carbon removed and if the trouble still continues, examine the hose connections to see if a loose flap of canvas caused by the rotting of the hose could have interfered with the water circulation. The radiator may be also flushed out with a few pails of boiling water to which has been added a handful of soda. It very often happens that oily water is inadvertently poured into the radiator and forms a non-conducting coating over the surface of the radiator. While this would not be apt to give such a bad case of overheating as you seem to have, still, in combination with hilly country, a rich mixture and a retarded spark, the tendency to overheat would be great.

2—It is necessary for you to get a new gear at once or else you will be in the unfortunate position of having to purchase another pinion also. It is useless to attempt to get a worn gear to mesh with a new pinion and to act noiselessly. It is not likely that this is the cause of overheat, although it may be if the resistance opposed to the motor is tremendously high. Jack up the rear wheel and see if it is very hard to turn the wheel around by hand. You can tell when the teeth of the gear and pinion are in proper mesh when there is no lost motion between them and when they run easily together. Improper mesh will be indicated by silence, although it can be detected by the eye to a certain extent if the light is good.

Specifications Show Good Truck

Editor The Automobile:—Will you kindly give me your opinion on the following specifications, for a 2-ton truck, allowing 30 per cent overload?

Do you consider the material specified of the best?

Does a truck with the following specifications compare favorably with other trucks selling at $2,800?

Specifications as follows:

Continental motor, 4 1-8 by 5 1-4, in sub-frame.
Clutch, Helie Shaw No. 5.
Transmission, Cotta, selective, three speeds and reverse.
Timken bearings connected on jackshaft.
Jackshaft, Timken, full floating.
Axle, rear, Timken, 2 1-4 by 3 3-8.
Axle, front, Timken, 1 3-4 by 3.
Frame, channel steel, 7 inches deep, 2 1-2 inches wide.
Springs, semi-elliptic, 40 inches long, 3 inches wide, front.
Springs, semi-elliptic, 54 inches long, 3 inches wide, rear.
Wheelbase, 140.
Front wheels, 36 by 5, solid tires, S. A. E. equipment.
Rear wheels, 36 by 3 1-2, dual tires, S. A. E. equipment.
Timken bearings in front and rear wheels.
Harrison radiator, suspended on coil spring.
Ignition, Bosh dual and Atwater Kent.
Carbureter, Stromberg.
Brakes, contracting on rear wheel drum and jackshaft.
Wheels, to have 2 1-4 inch spokes, 14 inches each wheel.
Hermer, steering wheel, 20 inches.
Shaft connecting clutch and transmission shaft connected with Blood Universal joints.
65 per cent., of load to be carried on rear axle.

Erie, Pa. George McLaughlin.

—These specifications are good and as compared to three of the standard trucks of that size which have made a name for themselves and which are satisfactory in every respect show that this truck is the equal of any.

Can Fit Vacuum Oil Feed

Editor The Automobile:—I am overhauling an old six-cylinder car and would be very glad if you can advise me through Letters Answered and Discussed as to the simplest way to install

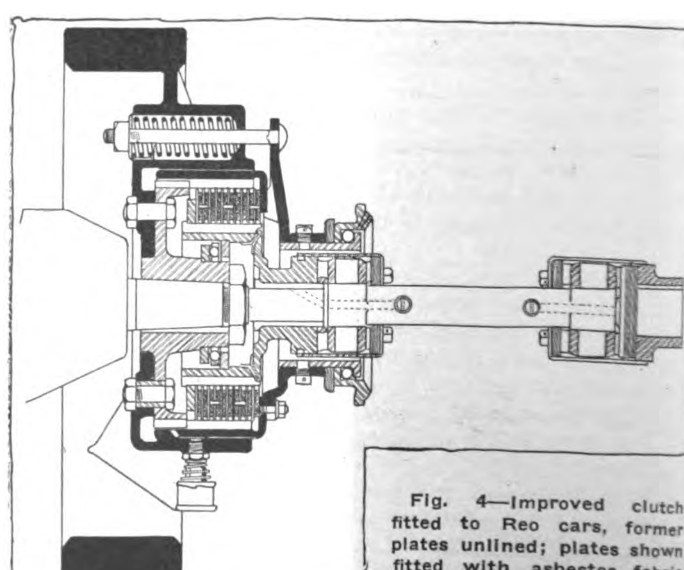

Fig. 4—Improved clutch fitted to Reo cars, former plates unlined; plates shown fitted with asbestos fabric

a constant level oiling system. Motor is lubricated by splash alone and no provision made for maintaining level, the practice of dumping in more oil from time to time as practiced several years ago being the only method of lubrication. Lower half of crankcase is divided with usual partitions between each cylinder, top of these partitions being about what is considered the normal oil level. It would be possible to establish a circulating system by providing a tank alongside of bottom of crankcase, thence overflow to tank, etc., continuously. I understand, however, that there is a simpler system in use in which a syphon effect is utilized in some way, this plan having been in use in Everitt cars as I understand it, same consisting of a tank from which oil is let into the crankcase by quantity sufficient merely to maintain predetermined level. In the old motor above referred to the division between each cylinder in the bottom of the crankcase—in short, between each oil well—is drilled through with a 3-8 inch drill at the bottom of the crankcase so that all the wells are in communication. It seems to me that by having the holes the divisions are made useless as all the oil would quickly run to one end or the other of the crankcase in ascending or descending a grade. Would it not be advisable to plug them up as with a means of maintaining a constant level flush with the top of the division walls all requirements would then be taken care of?

2—Also can you tell me of any parts manufacturer who makes a transmission and clutch as a unit as shown in cut, Fig. 5, page 1127, in your issue of November 28? I wish to purchase such a unit and would appreciate any information you can give, as I have been unable so far to locate any manufacturer of same.

New York City. C. J. WARD.

—A vacuum system such as used in the E-M-F cars could readily be installed. This system works as follows:

The oil tank is an integral part of the crankcase and is located on the left hand side of this casting. The capacity of the reservoir is about 1 gallon. The tank is filled through an opening in the forward end which is covered by a screw cap so made as to screw down tightly so as to form an air-tight fit over the oil reservoir. This tightness is an absolute necessity to the system as will be seen later.

The oil is fed into the crankcase splash troughs by vacuum. Two feed pipes extend from the bottom of the tank into the crankcase. These pipes are U-shaped, one end leading into the bottom of the tank, while the other projects through the bottom of the crankcase, to a point about five-eighths of an inch above the bottom. When there is no oil in the crankcase, but the reservoir is full, it can readily be seen that there will be a flow from the reservoir into the crankcase by means of these two pipes. When there is sufficient oil in the crankcase to cover the pipe ends, they will be sealed so that no air can enter them and hence no more oil may flow out of the reservoir.

This system automatically supplies the oil that is used just as rapidly as it is needed and keeps the oil level constant, since the pipes are continued into the crankcase for just such a distance as to provide the correct level for the splash of the connecting rods. The oil cannot rush into the crankcase and flood it when filling the tank as there is a valve which closes automatically when the screw cap is removed. There is an opening directly under the valve in the bottom of the oiler, through which the valve may be taken out for inspection in case of leakage. Any leakage would be detected while filling the reservoir.

The splash of the connecting-rods throws a spray up into the cylinder and fills the crankcase with oil vapor. This oil vapor lubricates the entire motor, including the camshaft.

The camshaft gears are lubricated through an oil hole and by means of grease cups which are provided for this purpose.

In order not to waste oil certain precautions must be observed in the monthly cleaning to which the crankcase should be submitted. The filler hole cap, on the oiler box must be removed so that the oil does not pour into the crankcase. The drain in the bottom of the crankcase is then opened until all the oil has poured out, when the drain cock is closed. Kerosene should then be poured into the breather pipes and the motor allowed to run for about fifteen seconds. The drain cock is then opened and the kerosene allowed to run out. After the drain cock is closed and the filler hole cover screwed firmly back into place the oil will run into the crankcase until it reaches its proper level.

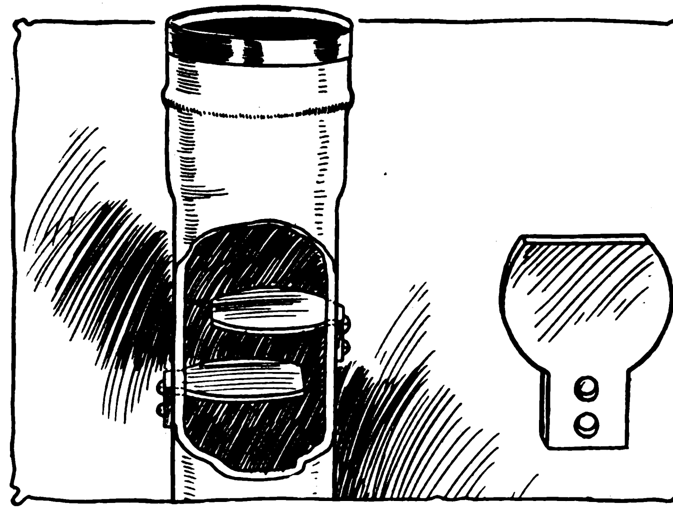

Fig. 5—Baffle plates can be fitted in breather to check oil spouting

It would be advisable to plug the division holes.

2—If you will apply to Victor W. Page, care of the New Departure Manufacturing Company, of Bristol, Conn., who submitted the sketch you will no doubt find where such a unit can be purchased because the oil will, as you say, run down to the rear end of the crankcase in climbing a hill. A point which should be observed in doing the drilling work necessary on this job is to remove all traces of metal borings as they might damage the motor seriously.

Position of Oakland Balance Weights

Editor THE AUTOMOBILE:—Kindly state the best method of setting the geared counterbalance on crankshaft of a two-cylinder 1909 Oakland engine. I do not get as steady a running at high speeds. I see no marks on gears but get them balanced by sighting them horizontally.

2—Can you suggest any remedy for oil being forced out of breather at crankcase when cylinder has apparently good compression? I added one screen.

3—Will a set of new clutch plates on slow speed in transmission prevent the very noisy hum when starting? What is the best oil to use with this clutch?

Oak Park, Ill. J. L. DAVIS.

—The only method is to take a trial setting and observe how the motor runs, then try another setting and see if running is better or worse. The first and second settings should be one tooth apart on the gears. That is, if the two teeth that are in mesh on the gears are marked in the first test the second test will consist of moving the tooth over one point on one of the wheels. The running should be observed on each test and the direction in which to make the changes will soon be noted. Should you be unable to secure silent running under any adjustment it will signify that the gears are worn and should be replaced.

2—The trouble is probably in the design of the breather which is not properly baffled. In Fig. 5 a method of constructing a new breather pipe is outlined. Two opposing baffle plates are fitted for the purpose of catching the oil thrown out. The breather is easily made; the upright piece of the breather may be the same as you have now. The two baffle plates are cut to suit the inside diameter and may be made of sheet brass. A gauze screen across the top will complete it.

3—A new set of plates would have a good effect in the direction of noise. The best oil to use with this clutch is a heavy steam engine oil thinned down with kerosene. It should be thinned down to the consistency of a medium cylinder oil.

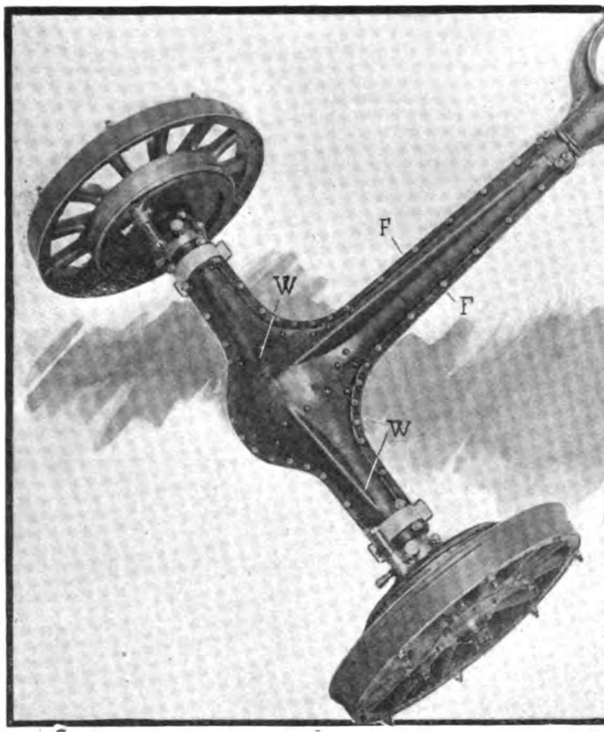

Fig. 1—Fiat pressed steel rear axle and combined torque tube.

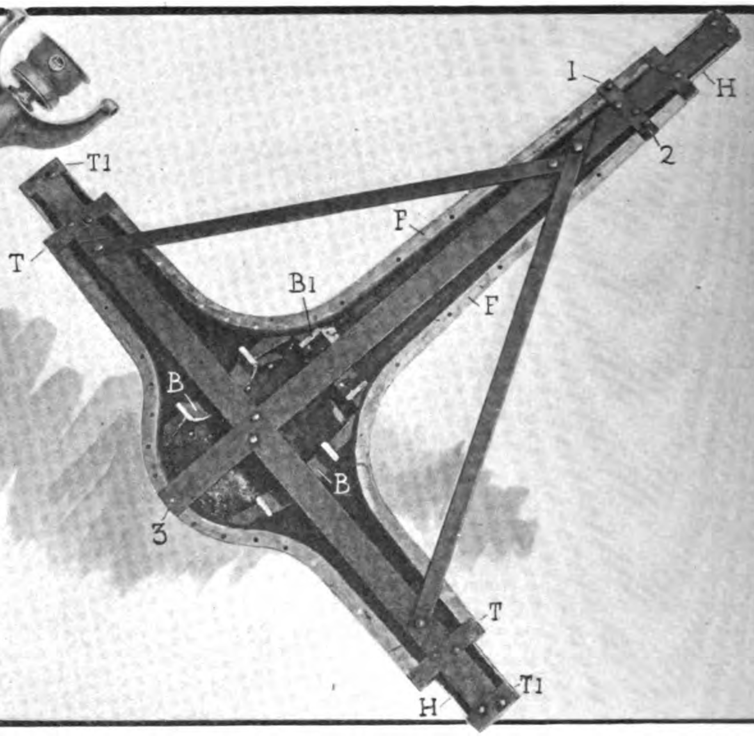

Fig. 2—Template used in cutting barrel ends of stamping to size

Fiat Rear Axle and Torque Tube a Unit

Factory Processes in Construction and Assembly of Combined Rear Axle and Torque Tube Stampings

Accurate Testing and Gauging Are Important Features of Company's Manufacturing Methods

THE last 3 years have witnessed general advances in rear axle construction. Interwoven with these advances has been the development of novelties, some with special merits, but often these offset by hidden disadvantages. The Fiat pressed steel rear axle and combined torque tube for the propeller shaft while unique in America has a following in Europe which is gaining. It has the complete housing made from two stampings made in the Turin factory of this concern. One stamping forms the top half, the other the bottom half, a series of cold-rolled steel bolts uniting the two. These stampings weigh in the rough 41 pounds each, giving the total housing weight little above the 80-pound mark, a fact which the factory can proudly boast of in these days when all Europe is aiming at reducing the unsprung weight of the rear axle. Not a few other European makers are cutting down unsprung weight. De Dion being a leader in that he uses the combination stationary and live axle, the stationary or unsprung part being but a forging extending from wheel to wheel whereas the differential and the drive shafts from it to the rear wheels are supported on the chassis frame, thus being carried through the springs and not coming under the classification of unsprung weight.

Each half of the Fiat rear system housing is stamped from a sheet of 50-point carbon manganese steel 4 millimeters, or approximately 1-6 inch in thickness. The utmost accuracy has to be maintained in the manufacture of these housings and the illustrations herewith show in a general way some of these processes. In making a rear axle quietness is the great aim, and quietness means proper meshing of the driving pinion with the differential bevel. The Fiat company has constructed this axle housing along the line of getting this meshing correct in the factory and not making any provisions for disturbing it by the car owner or the casual garageman; in a word, it is a non-adjustable axle with the axle drive shafts not withdrawable.

To get the desired accuracy in the housing and the mounting of the differential and pinion it is necessary to treat each stamping with the utmost care. First in this comes the preparations of the flanges F, Fig. 2, where the halves bolt together. These flanges, to reach the desired degree of accuracy, are gone all over with a hand file, are then finished with emery cloth and finally shellacked, thereby eliminating the use of a gasket and yet giving an oil-tight joint. This necessary accuracy of the flange faces is tested on a huge metal surface plate, not illustrated.

After accuracy in these flanges has been obtained it is necessary that the halves be rigidly held together, which is done by 5-16-inch cold-rolled steel bolts placed 4.5 inches apart on the straight portions of the housing and much closer at the four curved portions in the proximity of the differential expansion.

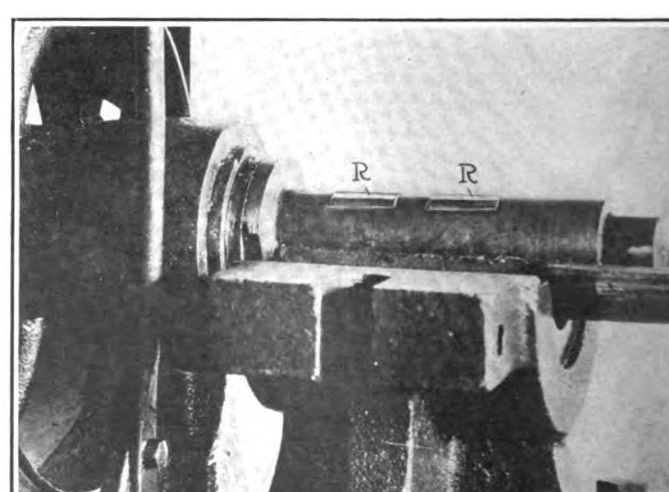

Fig. 3—Detail of hub truing operation

where the strains of the differential and driving pinion are set up. Further strengthening of the expansion is by the heavy webbing W, Fig. 1.

But the preparation of the flanges is only one part of the work on these stampings. They must be of correct measurement which is accomplished by templet, Fig. 2, which serves several purposes. Its iron cross-piece carries a part T which determines the exact length of the flange, and another part, T1, fixes the length of the further extension of the flange in the form of a hub. A similar cross-piece fixes the length of the flange at the forward end of that portion of the housing constituting the torque tube, and another determines the length of the tube. The templet has three anchor points designated respectively 1, 2 and 3 which are the fixed layout marks for the housing.

After the stamping has been cut to the correct size the three ends or hub portions have each to be brought to perfect semi-cylinder in order to mount them accurately in the brake drum carriers. This work is done by a special machine, Fig. 5, in which three truing hubs H1 fit and are revolved. The exact nature of these hubs is better shown in Fig. 3, in which it will be seen that a series of short rollers R carried in slots with provisions within the sleeve carrying these rollers to force them out radially as desired. The operation of the truing up of these three hubs consumes 20 to 30 minutes. When the operation is in progress caps K, Fig. 5, are fitted over the expanding parts, these being removed in the illustration for clearness. This done there is the necessary trimming of the flange edges, which is a minor operation.

Truing of Hub Ends

After this expansion of the hub ends a test gauge, Fig. 6, is placed in each half of the axle and the portions of this test gauge fitting within the hub ends is painted with a color preparation to ascertain if the hub portion completely coincides with the curvature of the gauge.

The next major work in this axle construction is that of mounting and preparing the three brackets B and B1, Fig. 2, on which the differential and driving pinion are mounted. These brackets are steel castings riveted to the stampings. Once in place they have to be accurately prepared for the bearings. These brackets B are first bored one-half at a time. The bracket B1 is similarly bored, the boring fixture being secured at the forward end of the torque tube in order to insure the desired accuracy. In addition to boring the bracket B1 is hand reamed, Fig. 4 showing the hand reamer R in place together with the fixture J with its two bosses of exact size of the bearings carrying the differential and resting on the brackets B. The reaming shaft is anchored at R1, the forward end of the torque tube to gain the greatest accuracy. When this hand reaming is taking place both valves of the stamping are bolted together, the upper one having been removed in the illustration in order to show the reamer.

Special fixtures are used on the boring machines to insure accuracy of the brackets B.

Many of the internal details of the Fiat axle cannot be obtained from photographic reproductions, but appear in Fig. 7. The drive shafts S support the rear wheel on a slight camber of 1 per cent., to be more explicit 1 millimeter camber to every 100 millimeters of drive-shaft length. The road wheels are fitted to a taper with key and at the inner ends the differential bevels are similarly fitted. The inner end of each shaft takes a hardened piece P which is sunk into the end of the shaft and pinned. The oppos-

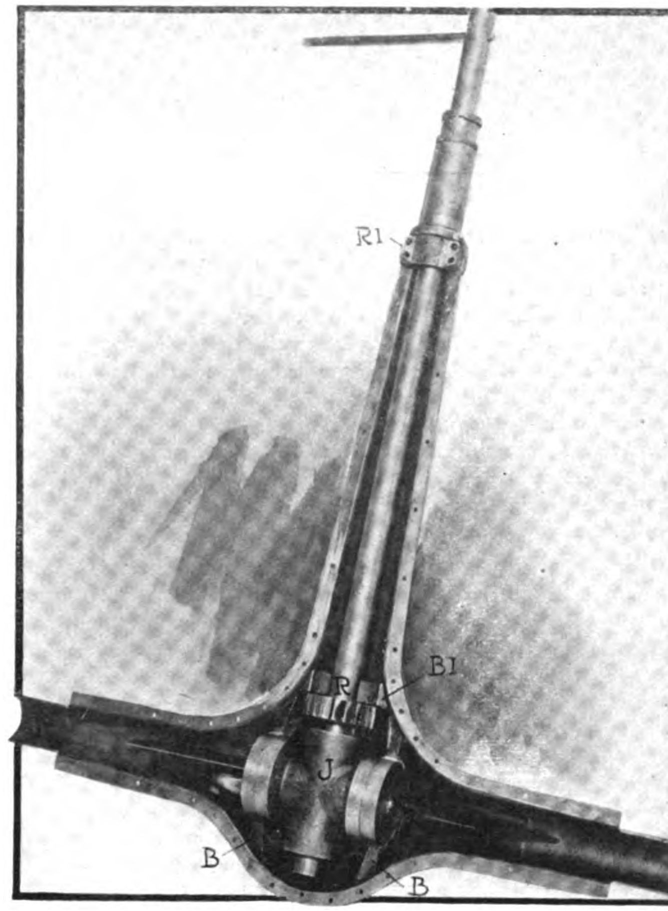

Fig. 4—Showing method of hand-reaming of pinion bearing in Fiat rear axle. During this operation both stampings are firmly bolted together

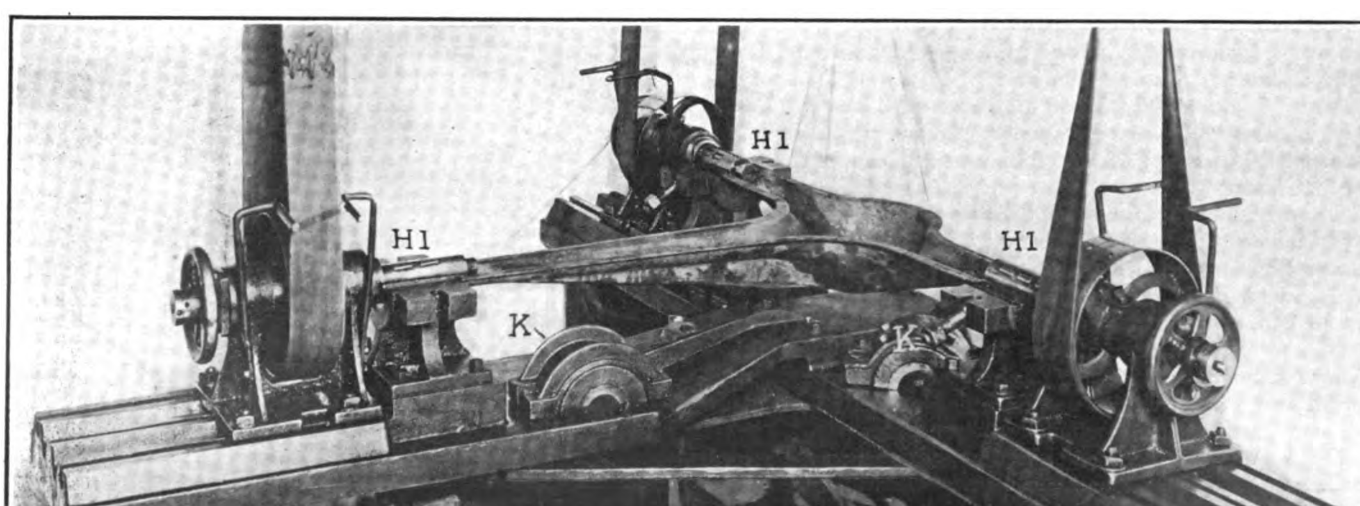

Fig. 5—Machine used for simultaneous truing of all three barrel ends of Fiat rear axle stampings

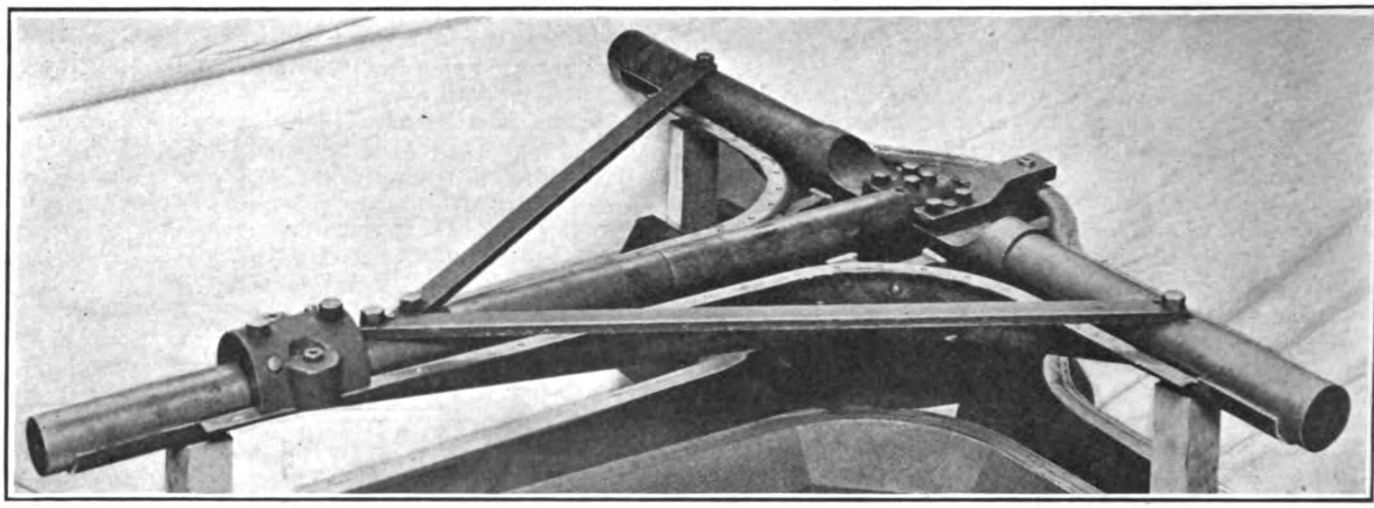

Fig. 6—Combined T square gauge and drilling jig for Flat rear axle

ing faces of these pieces bear together constituting a thrust bearing. In addition to this there are three other thrust bearings, one at each side of the differential and one in advance of the pinion. Four R. I. V. annular bearings are used to carry the differential and axle shafts and a double race of these bearings supports the pinion fitted to the rear end of the propeller shaft. The forward end of the propeller has plain bearing at the point Y. The fork or yoke X supporting the torque tube has the axis X1 in line with the axis of the universal joint thereby giving the desired action.

The rear brakes, as shown in the inset Fig. 7, are of large diameter, giving great braking power. They are double-acting, with expanding shoes A and contracting shoes B.

Harking Back a Decade

FROM *The Automobile and Motor Review*, December 13, 1902:

A project is being seriously advanced to connect New Jersey with New York and the north Atlantic coast by a macadamized highway across the Newark meadows. New Jersey has from 1,200 to 1,500 miles of finely improved roads but it is exceedingly difficult to reach them from New York. Flat steel rails will be laid in Murray street on the Manhattan side and it is expected that the new road will extend from Marion on the Hackensack river to Harrison on the Passaic cutting between the Lackawanna and Erie tracks.

The first Peugeot coupé imported into the United States has attracted a lot of attention recently on the streets of New York. The car has a two-cylinder motor, carried beneath the body in the rear. Ignition is by hot tubes. Its speed is from 4 to 25 miles an hour.

Henry F. Donaldson, editor of *The Automobile and Motor Review* has gone to Paris to report the automobile show and later will make a tour of inspection covering various large continental factories.

The question of licensing automobilists is agitating the national organizations. The A. C. A. recently went on record as favoring a state license; the N. A. A. M. wants federal license. The A. A. A. and A. M. L. have taken no definite position on the matter to date. Conditions are becoming intolerable through the passage of laws and ordinances in various localities without definite standard, making it a misdemeanor to operate an automobile in a certain way in one town and perfectly legal to use the same methods in the adjoining village.

The A. A. A. has declined to receive and sanction the records made at Detroit last month by Barney Oldfield in the Ford racer. This leaves the record for the flying mile on a circular track to the former holder, Alexander Winton. The Oldfield trials were timed with stop watches held by Dr. R. C. Rudy, William E. Metzger, E. H. Broadwell and J. M. Colquhoun.

Exports of automobiles and parts from New York during October reached a valuation of $122,624. For the first 10 months of the calendar year they were $970,610. This showing compares with $55,735 and $262,537 during the corresponding periods of 1901.

Warrant for the arrest of E. J. Pennington, who has cut a wide swath in the automobile and airship field in the United States and England, has been issued at the request of a Cincinnati hotel where he stayed this fall. Pennington is said to have sold his airship patents to Great Britain for $5,000,000 a short time ago but that his activities in buying automobile factories exhausted his capital.

German Daimler cars are being duplicated by the Daimler Manufacturing Company, of Long Island City, L. I., and will be placed on the market shortly. One 12-horsepower car, an exact facsimile of the foreign built model, has been turned out.

Communications from The Manufacturer

H. H. Franklin on Annual Models—P. W. Litchfield on the Breaker Strip —Owners and the Care of Rims

SYRACUSE, N. Y.—Editor THE AUTOMOBILE:—The editorial in your issue of November 21, entitled The Annual Model, was about the weakest statement I ever saw on the subject. You attempt to show conclusively that the American automobile is not sufficiently developed to warrant the elimination of the annual model.

The development of a car, namely, its degree of perfection, has nothing whatever to do with the annual model question. You also say that so long as automobile shows are held it will be necessary to have the annual model.

You must have written the editorial to please the annual modelers. Or else you are in possession of a fine large fund of ignorance on the subject.

Improvements can be, should be and are made in automobiles regardless of annual models.

Just when improvements are made is usually a question of the manufacturer's stock, both raw and made up. This is sometimes offset by the character of the improvement required. If it is something that must be taken care of to preserve the car's quality and the manufacturer's standing, it will be done at the earliest practical moment no matter what the loss in stock on hand. The improvement demanded may be something to overcome weakness in design or material, or both.

When the front door bodies appeared some makers attempted to go through the season without that type of body. They had announced their annual model, but they got the front door on as soon as they could. They did not wait for another annual model announcement time.

Right now makers who announced their 1913 models without starter are moving heaven and earth to get starters on. They would be in a fine fix if they waited until the 1914 model was ready. Some who announced starters are already changing to other types, and so it goes.

You will find that the makers who have abandoned the annual model plan will be at the shows this winter with right up-to-the-minute product. They are likely to be more up-to-the-minute than the annual modelers, because their manufacturing plans are worked out on a more flexible basis. They can make improvements easier and with less expense. They are really in position all the time to take advantage of today's advancements.—H. H. FRANKLIN, H. H. Franklin Manufacturing Company.

AKRON, O.—Editor THE AUTOMOBILE—There are still occasional tire users who do not fully understand the function and purpose of the breaker strip, which lies along the tread of the Goodyear automobile tire, concealed by the tough rubber of the tread. The explanations occasionally given for the presence of the breaker strip are entertaining, to say the least.

The breaker strip is put in a tire to take the shocks which obstructions in the road are liable to give to a tire, before they can reach the organic part of the tire. It plays no part in the strength or efficiency of the casing, but is simply an armor belt around the outside of the tire to protect it from injury.

The body of the tire, to give the best results, is made of fairly close-woven fabric placed at an angle of 45 degrees. The tread rubber, to give the best wearing qualities, is made thick and tough, and while in service exerts a drag on the fabric, tending to pull it loose. The breaker strip should be put in with the treads running around the circumference of the tire, instead of at an angle of 45 degrees, as this more effectively takes up the shocks without transferring them to the carcass and better resists the drag on the rubber, pulling it away from the tire fabric.

When sharp stones or glass cut the tread rubber, in many cases the abrasion is stopped at the breaker strip, preventing the water and dirt getting down to the main fabric, thereby preventing the tire being water soaked or sand blistered to quite an extent. As the breaker strip is the nearest fabric to the road, it receives all the cuts, water, dirt and sand, and should be made, so far as possible, to resist damage caused by them. For this reason we wish an open fabric which can be more effectively united to the rubber. On the other hand, we wish a closely twisted yarn, tightly woven, to avoid becoming spongy when water soaked, thereby letting go from the rubber. We believe that our rivet fabric is the best compromise between these two qualities, as it is made from closely twisted yarn, tightly woven, to make it as waterproof as possible, but leaving large holes at intervals through it, which result in the formation of large rivets of rubber, making a fabric which is more closely united to the rubber than any ordinary loose-woven fabric, and at the same time it is more waterproof after the tread has been cut.

Always bear in mind when you have breaker strip trouble that undoubtedly this has saved the tire from much more serious injury at a much more vital point in its construction. To obtain the best results from breaker strips there should be a cushion of rubber between the breaker strip and the main fabric of the tire.—P. W. LITCHFIELD, Goodyear Tire and Rubber Company.

CLEVELAND, O.—Editor THE AUTOMOBILE—Of all the component parts of the automobile, perhaps the most widely discussed by the press and by users is the motor, and those parts which receive least consideration, if any at all, are the rims on which the tires are mounted. Although rims are operating mechanical devices, they are seldom looked upon as such by the car owner, even though he may be thoroughly familiar with every other mechanical feature of his machine. And yet there is no part of the automobile which receives more severe service.

Often, when a blow-out or puncture takes places on the road, your car owner will be confronted with an entirely new problem—he will not know how to go about removing the tire from the rim. If his car is fitted with demountable rims he is a lucky man, for in that case he can put on the spare tire without much trouble. But let him try to get the tire off the rim and he will begin to find cause for complaint in the rim. Yet if the rim had been investigated and its construction understood the operations connected with its removal would have been simple.

Rim makers of today have given as much thought to their product as have the manufacturers of any other product, and perfection along this line is as nearly attained as elsewhere. Tire replacement is not the burden now which it was in the past, but the new devices must be understood for their extreme simplicity to be apparent. Not that they are complicated by any means, but there are certain special operations connected with their use with which every car owner should familiarize himself.—Standard Welding Company.

NEW ORLEANS, LA., Dec. 6—In the French quarter, laid out nearly 200 years ago, there has been great difficulty in handling the traffic, owing to the narrowness of the streets. In the last report of the chief of police, he states that, due to the increased number of motor vehicles it is now possible to reduce the traffic squad materially in the old part of the city. When horses were used altogether, the lives of pedestrians often were endangered by the animals becoming unruly in the jam at street intersections. Motor vehicles have radically changed conditions.

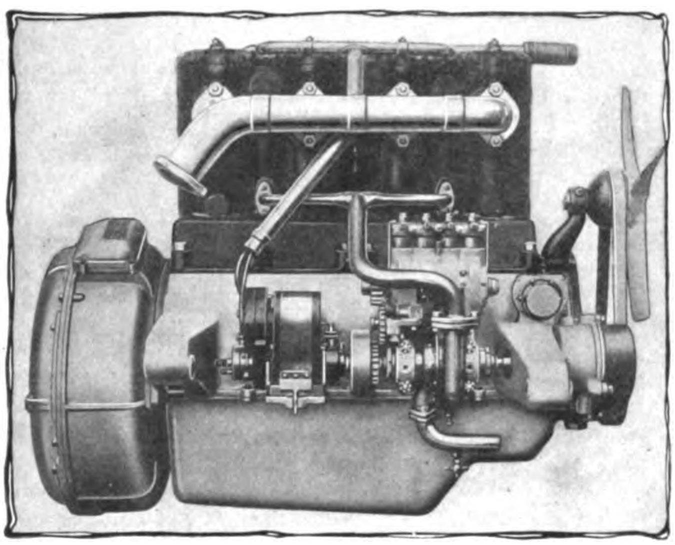

Fig. 2—Exhaust side of the new motor, showing disposition of chain-driven magneto and pump

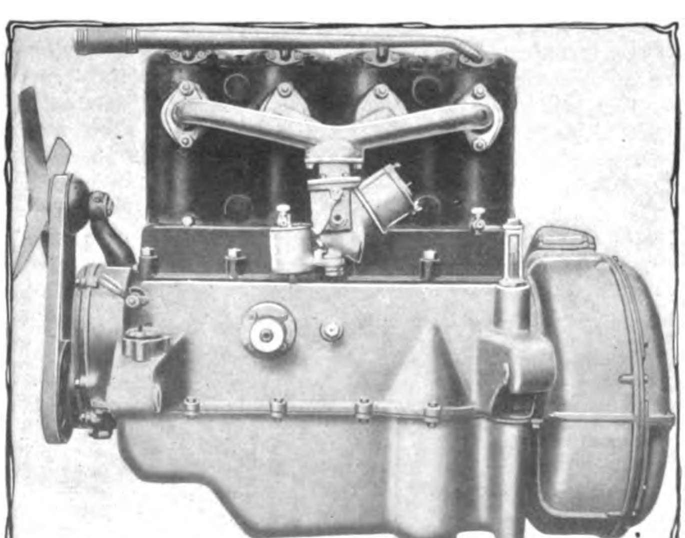

Fig. 3—Intake side of the Edwards-Knight. The flywheel housing at the right contains an electrical self-starter

Notable Features of New Car Include Electrical Flywheel Starter—Unit Clutch and Gearset—Worm Drive

THE Edwards-Knight is out. This latest addition to the list of American-made cars was originally announced last February when C. G. Stoddard and H. J. Edwards withdrew from the United States Motors and immediately launched the Edwards Motor Car Company, of New York City. At that time announcement was also made that Messrs. Stoddard and Edwards had secured from Knight & Kilbourne the last American license to build automobiles under Knight patents, that is, using two sleeves in place of poppet valves.

The Edwards-Knight is a specially-designed automobile. To summarize, it is a 25.6-horsepower, four-cylinder type, with 4-inch bore and 5.5-inch stroke; the motor uses silent chain drive for the eccentric and magneto shaft; it has force-feed non-splash lubrication; it has an electric self-starter incorporated within the inclosed flywheel; the dry-disk clutch is carried in a separate compartment in the forward part of the gearbox; the gearbox is flexibly supported and has four forward speeds; worm drive is used in the rear axle, with the worm beneath the axle yet affording a 9.25-inch clearance; detachable wire wheels with Q. D. rims are used; the steering wheel is on the left side with center levers; Lanchester patent springs are used in the rear, and the frame is double dropped.

The chassis embodying these features is made with 120-inch wheelbase and takes two-passenger roadster, four-passenger torpedo, five-passenger touring car, seven-passenger limousine and seven-passenger landaulet bodies. Prices are $3,500 to $4,700.

The present chassis model 25 possesses new features in torque and radius rod design as well as universal joint action in the propeller shaft.

The motor incorporates all of the 1913 improvements that the European licensees have made in the Knight type, including long-stroke, namely, a stroke-bore ratio of 1.35 to 1; longer stroke of the sleeves; making both inner and outer sleeves the same thickness, and change of timing to give a maximum opening of the ports on both intake and exhaust strokes.

The twin cylinder castings are imported, as are the cast-iron sleeves and pistons. Water pump, Simms magneto and tire pump are grouped on the right side, all driven through a longitudinal lay shaft; on the left are the S. U. carbureter and the air pump for gasoline pressure, leaving this side clean for the steering column.

The motor uses a five-bearing crankshaft 2.25 inches in diameter. It has all main bearings and crankpins drilled for lightness. The flywheel anchors to an integral flange and at the center bearing are two flanges F, Fig. 4, which care for the end thrust. The bearings are bronze lined with .03125 inch of babbitt.

Connecting-rods are tubular forgings of round section, drilled out to reduce weight and leaving a wall thickness of .125 inch which is increased to .15625 inch at one-third the height of the rod, which is the point of greatest strain.

Pistons with concaved heads carry three eccentric rings above the wristpin and are relieved from the lower ring to the wristpin to facilitate lubrication. The skirt is perforated. An allowance of .012 inch is made at the top and .0035 at the piston base.

The wristpin is a hardened and ground steel tube working in a steel bushing, the bushing being hardened, ground and lapped.

The silent chains used to drive the eccentric and lay shafts are non-adjustable. The drive to the eccentric runs on pulleys with 6.676-inch centers and that to the magneto with 8.8225-inch centers. Both are broad and of 6 pitch. Lubrication is through the forward end of the drilled crankshaft and out through radial holes, 1, 2 and 3, Fig. 6, and thence by centrifugal force outward through holes in the pulley into the chain.

The operation of the Knight sleeves is well understood. Here they have a reciprocation of 30 millimeters, or 1.18 inch, which is longer than previously used and results in longer intake and exhaust openings. The intake ports are on the left side, the exhausts on the right, and both have a circumferential length on the sleeves of 3.5 inches. The intakes are 12 millimeters, .472 inch high, the exhausts 18 millimeters, or .70 inch. In other words, the intake port is equivalent to 1.645 square inches opening and the exhaust to 2.45 square inches.

The intake opens 15 degrees late and closes 36 degrees late, giving it an opening of 210 degrees. The exhaust opens 55 degrees early and closes 5 degrees late, a total opening period of 240 degrees. With this motor the power efficiency is not only due to the area of the port or valve openings, but also to the length of time they remain open as well as to the rapid opening and closing. This is graphically shown in the timing chart, Fig. 10.

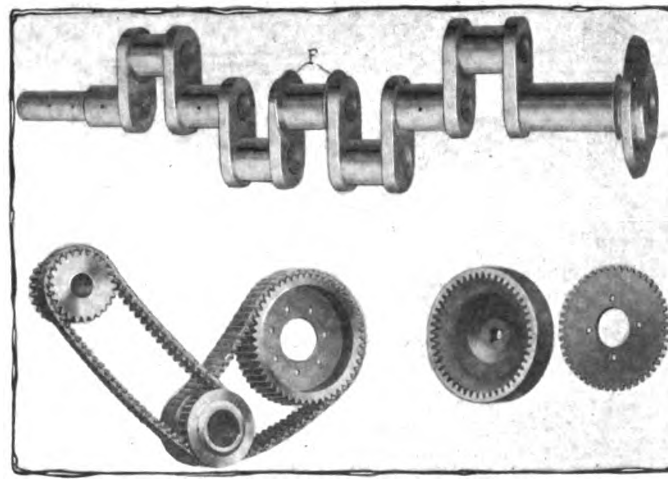

Fig. 4—Top view shows hollow crankshaft with integral flanges at the center main bearing to take end thrust. Below, arrangement of silent chain drive for eccentric and magneto shafts

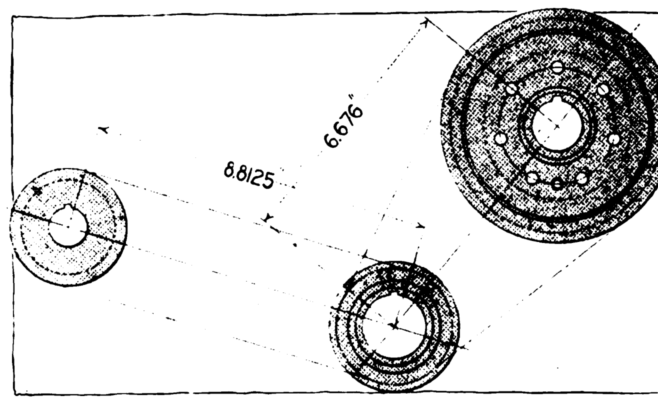

Fig. 5—Relative position and sizes to scale of magneto and eccentric shaft chain drive

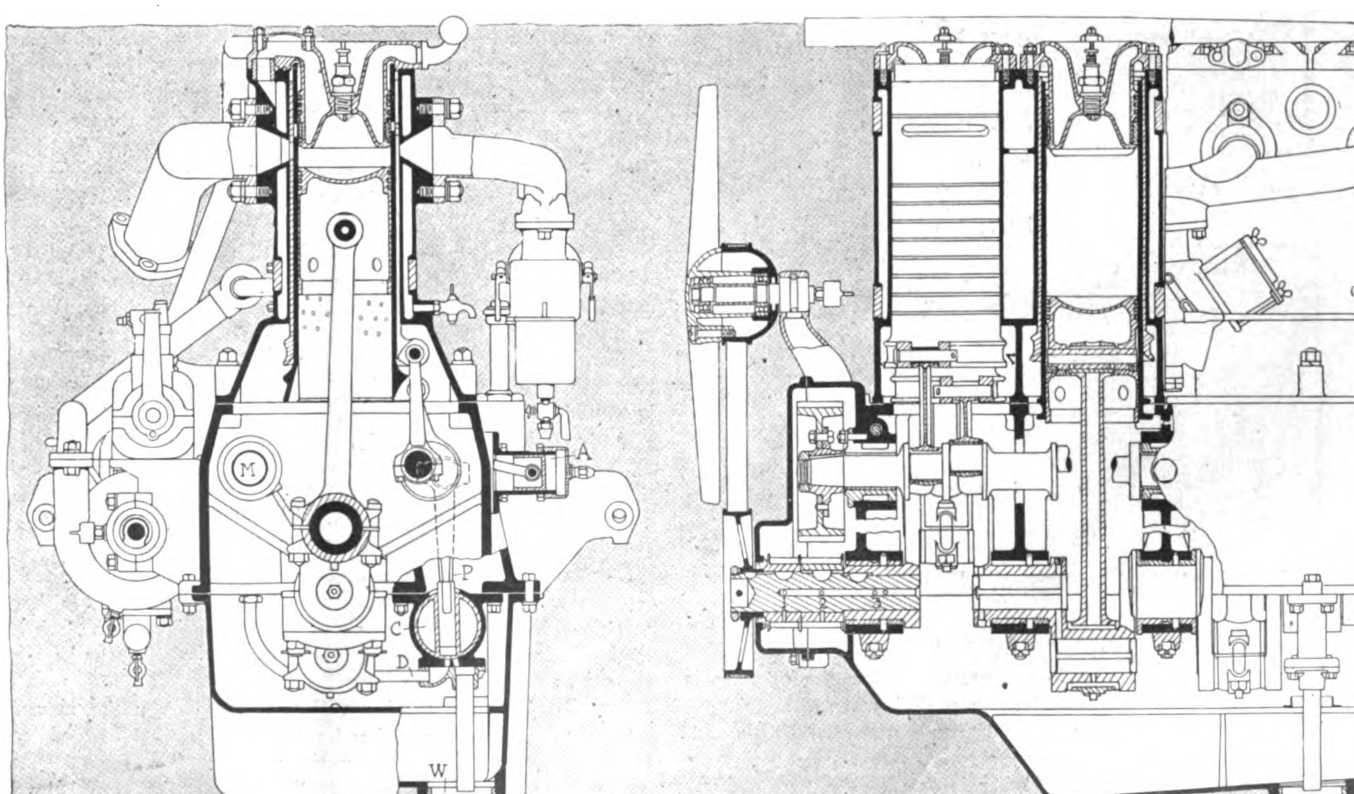

Fig. 6—Cross-section and partial longitudinal section of the Edwards-Knight 25.6 horsepower motor

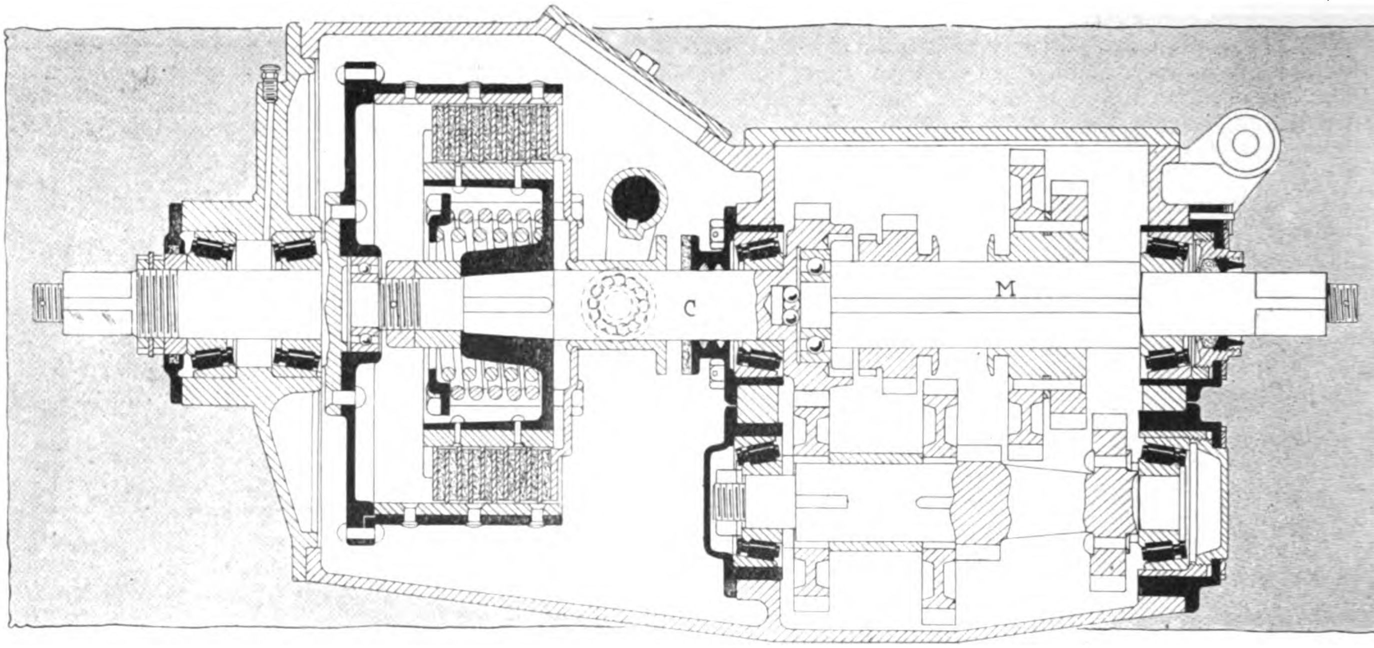

Fig. 7—Combined dry-disk clutch and gearset. Note oiltight dividing wall and use of roller bearings

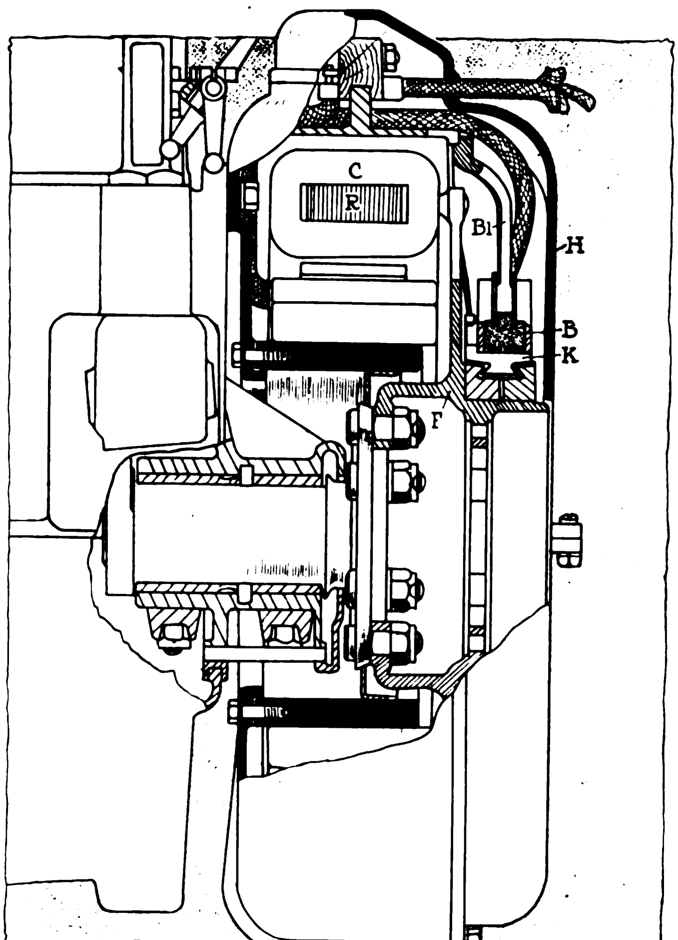

Fig. 8—Sectional view of electrical self-starter attached to rear end of crankshaft

The intake opening chart is practically a 45-degree opening line and also closing line; and in the exhaust valve the opening is quicker and there is a considerable period when the port remains at maximum opening, this being represented by the flat top of the diagram.

This quicker opening and closing is due to the two reciprocating sleeves which are so timed that in intake opening the inner sleeve moves up and the outer sleeve down. The inner sleeve beginning its acceleration and the outer sleeve at its maximum speed of travel. To close the intake the inner sleeve alone moves upwards at maximum travel against the junk ring in the cylinder head, which gives the gas sealing necessary. The exhaust ports are opened by the inner sleeve lowering at maximum speed from the junk ring and are closed by the outer sleeve on its downward motion.

Lubrication is an improved non-splash pressure system without any auxiliary feeds to cylinder heads or sleeves. A single-plunger oil pump located within the crankcase base supplies lubricant at a pressure varying from 2 to 20 pounds according to the demands. The plunger P, Fig. 6, operates direct from the eccentric shaft and works in an oscillating cylinder C, whose oscillations are so timed that its bore registers with the intake pipe from the oil well W on the upstroke of the plunger and with the discharge pipe opening D on the down-stroke. The discharge pipe connects with a large conduit M incorporated in the crankcase when cast, and which conduit has distributing branches to all five of the crankshaft bearings; thence, through the drilled crankshaft and the hollow connecting-rods and hollow wristpins, the positive oil pressure of the pump reaches all of the important motor bearings, etc. The motorbase has an oil capacity of 2.5 gallons.

Stock equipment includes an electric self-starter of the U. S. Light & Heating Company type incorporated within the flywheel and weighing approximately 100 pounds extra and being entirely within the housing containing the flywheel. Fig. 11 shows the housing H and the rotating portion of the starter R. These parts are also shown in the sectional drawing Fig. 8. The rotor R is mounted on a spider F and carries a series of coils C. The commutator K is fixed on the hub portion of the spider, the brushes B being supported though arms B1. To start, current is drawn from a battery and once started the battery is recharged from the starter which assumes the rôle of a generator. The starter control is in a small lever on the dash.

The magneto timing can be adjusted by changing the mesh of the gears. Closely associated with the ignition system is that of the four-cylinder power tire pump driven by gear from the pump shaft. The tire pump is snugly nested above and back of the water pump.

The S. U. carbureter is an English production the manufacture of which in America has been secured by the Edwards company, and its cardinal characteristic is that the area of the air space surrounding the nozzle is automatically varied by the motor suction acting on a bellows which in turn controls a piston. This piston obstructs the air passage. With high motor

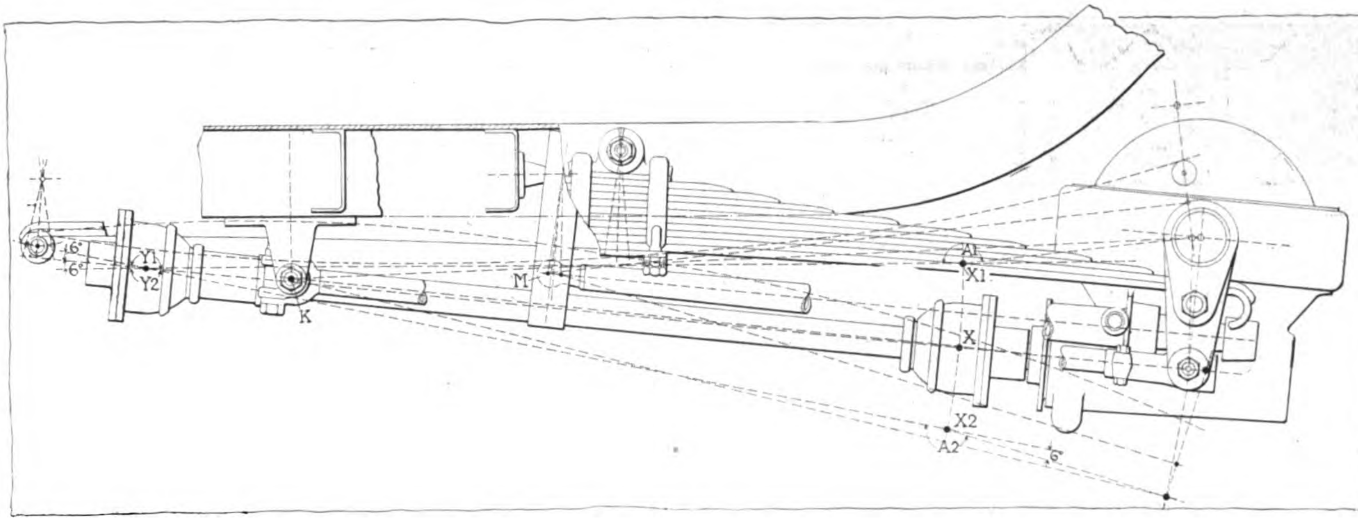

Fig. 9—Diagram explaining the action of the torque rod and distance rods which is such that no sliding takes place in the universal joints of the propellershaft

speeds the piston is drawn out of the passage, increasing its area and thereby lessening the suction on the gasoline in the nozzle and giving that desired reduction of richness in the mixture, whereas with low motor speeds this governing piston largely obstructs the air passage thereby increasing the suction pull on the gasoline in the nozzle and giving a richer mixture. The governing bellows is contained within the cylindrical part of the housing, Fig. 3, which is mounted at approximately 45 degrees. The vertical cylindrical chamber contains the float. Air pressure for the feed is through a simple plunger pump A, Fig. 6, driven from the eccentric shaft.

The combined gearset and clutch is shown in Fig. 7, the clutch a dry-disk type with its steel disks faced with asbestos and all contained within a separate compartment and supported in front on a double race of Timken rollers and in the rear by a single race. The clutch shaft is carried within the recessed end of the crankshaft in a ball bearing and it is formed with an integral gear on its rear end within the gearbox proper and supports the mainshaft M on an annular ball bearing and carries also a ball end thrust. The remainder of the bearings of the set are Timken rollers, the short-series type, oiltight bearing plates and packing are used. Nickel steel is used throughout for gears and shafts. There are four forward speeds with direct on third. The gearbox is flexibly mounted on two frame cross-members, in front through a trunnion and through two points at the rear where a fore-and-aft hinge motion is afforded.

The Edwards-Knight has a straight-line drive in that the motor is mounted to decline slightly to the rear, to be accurate, the angle is 4 degrees; and the gearbox is similarly declined so that with the car loaded the crankshaft, the mainshaft of the gearbox, the propeller shaft and the worm shaft in the axle are all in a straight line.

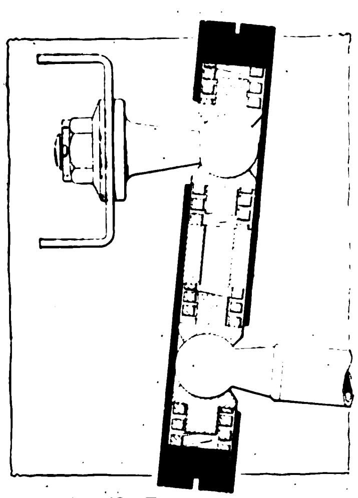

Fig. 12—Flexible torque rod fastening

To understand the merits of the propellershaft system it must be remembered that a torque rod and two distance rods are used that the length of these is such that they work in unison and eliminate all sliding movement in the universal joints. The angles in the front and rear universal joints are the same at all times, namely, the angle between the gearshaft and the propellershaft in the front joint equals the angle between the propellershaft and the wormshaft in the rear joint, a fact which neutralizes the acceleration and retardation which take place twice during each revolution in a universal joint. Fig. 9 will aid in explaining this: The arc Z contains three indicated point, X, X1 and X2, which represent the rear universal joint at three positions, normal in the center,

Announcement

BEGINNING next week THE AUTOMOBILE *will start the publication of a series of articles entitled Criticisms of Non-Poppet Valves To-Date, by Eugene P. Batzell. These articles will appear from week to week in relatively short instalments so that the busy man of the day and the onslaught of holiday activity will not make the following of them from week to week, a difficulty with any reader.*

In his treatise on the subject Mr. Batzell, who has approached the subject from the viewpoint of the practical engineer, takes up seriatim the many types of non-poppets that have been invented and brought into the practical stage to one extent or another. He points out the various shortcomings of many of the types as shown in practice and analyzes the inherent weaknesses of others that in some cases have progressed little beyond the patent office stage.

The able manner in which Mr. Batzell deals with any subject he undertakes to write upon is well known through his papers presented before the Society of Automobile Engineers, which have invariably shown keen engineering judgment coupled with a wide knowldge of modern practice. In Criticisms of Non-Poppet Valves To-Date he has accommodated his language to the intelligent car owner, to the intelligent dealer as well as combining in his sentences many new thoughts on the situation which cannot but stimulate activities among the engineering fraternity of today.

Fewer Models—More Cars

Foreigners Imitate Americans

ALL manufacturers must come to the rational order of things or die a premature death. This is most apparent to-day in the phenomenal change that has swept over the makers in the question of multiplicity of models. The time was when one concern boasted that it had twenty-one different models for a certain year. Each model had its characteristics and while the company had not twenty-one different motors it had over half that number of different cylinder dimensions, wheelbases, angles to steering columns, wheel sizes and other specifications. It deemed that such a scale of models was necessary in order to meet the requirements of the fastidious public.

To-day this is changing and changing rapidly. Business competition is working the change. Companies with seven different models in 1912 are cutting them to three for 1913 and some extremists have dropped from a variety program of six to a single one for the ensuing year. All through the list of car manufacturers, where there has been a needless multiplicty of models there has been a pruning for next season.

Some makers have ben inexcusably slow in discovering the amount of factory disorganization occasioned by so many models. Only with the present reduction in prices, made possible in many cases by increased production and elimination of models, have they realized the losses due to upsetting the factory every few days or weeks in order to run through a line of parts for the various models. They have at last weighed the situation and discovered the loss of time in actual machine operation and coupled with which is the lack of workman capacity for a period after each change is made.

Our biggest producers have naturally been the first to act on the model-reduction program. Output has made it imperative with them, and frequently it was essential with them to have output in order to meet the listed price of rivals. But one of our big holding companies has gone still further in this centralizing program and instead of cutting out models of the same make has been gradually reducing the number of subsidiary factories, dropping one here and another there and, as each is disposed of, centralizing on the others and multiplying their annual product. The dollar-and-cent value of this good judgment cannot be overestimated. It facilitates work all through the factory gamut.

In this respect the German engineer must be credited with going perhaps a little further than his rivals in that he has been busied in research work for several years in which he aims not only at reduced cost of output but at putting a little better workmanship and a little better design and a little better material into his car. The laboratories of Germany have been activity-centers for the last few years. Much of the research information has been kept private or issued at the end of each year in booklet form. Even in these the usual German brevity in matters technical is apparent, and the engineer who would follow closely the research of the German must read closely between the lines and put continuous study into his work.

Indianapolis and Detroit Sections of S. A. E. Meet

E. B. Van Wagner in Paper on Metallurgy of Motor Bearings Recommends S.A.E. Standard Babbitt—Discussion on Swiss Slide Valve Motor

INDIANAPOLIS, IND., Dec. 6—The November meeting of the Indiana branch of the Society of Automobile Engineers having been postponed on account of Thanksgiving, it was held Thursday night, December 5, at the regular meeting place—the Hoosier Motor Club rooms in this city.

The subject under discussion was the Metallurgy of Gasoline Motor Bearings, the speakers of the evening being Mr. Van Wagner, of the Van Wagner Die Casting Company, Syracuse, N. Y. The chief points of interest in the talk embraced the following:

At the present time there are three classes of bearings in use on gasoline motors—the ball roller and anti-friction metallic bearings. With the exception of the Chalmers and the Lozier, which use ball bearings, practically all automobile manufacturers in this country use anti-friction bearings either in the form of die castings or as sand cast alloys.

The design of motor bearings is interesting and not understood by the average layman. A feature developed with one manufacturer of high-speed motors in that the use of different bearing materials influenced the speed obtainable from the motor. The design of bearing naturally resolves itself into the question of length and diameter, which should be as small as possible in accordance with the pressure and work expected from it.

Best Alloy Depends on Shaft Material

There are four main points to be considered in the selection of a bearing for any special position, namely, the dimensions; selection of the proper material; the anchoring and the clearance between bearing and shaft.

In the anti-friction bearings there are two kinds being used. The anti-friction white metal and the bronze bearings. The anti-friction bearings are commonly the white brass ones backed by a bronze backing. The advantage of having this soft plastic metal next to the shaft lies in its capacity to shape itself to the shape of the shaft and more nearly form a perfect surface than in the case of the bronze where hard spots are likely to develop.

The selection of the material of the alloy used depends upon the shaft material; the temperature developed: the friction and pressure and the cost.

The lubrication of bearings is a very important feature in the determination of the alloy used. Soft white brass compositions have a quality of self-lubrication—a decided advantage over the bronze.

As to the cost of the two materials, notwithstanding the fact that the ingredients of the white brass are more expensive than the bronze, the fact that it is much easier worked brings down the final cost lower than that for bronze.

From experiments, the Society of Automobile Engineers standard of babbitt has been found best—having no tendency to flake—which feature is very noticeable in the majority of the alloy bearing metals.

The last point in the selection of a bearing, namely, the clearance, is an important one. There is a tendency to make the fit too close and not allow space enough for the film of oil.

The following discussions by Howard Marmon, of the Nordyke, Marmon Company, Mr. Wall of the National, and Mr. Wood, of the Indiana Die Casting Company, proved of interest.

Instead of using the customary bearing which consists of the plastic white brass backed by the bronze, why not use the white brass die castings with no backing? This might be satisfactory where the pressure on the bearing was not too great. Is it not a fact that the unequal expansion of the two metals, when submitted to the high temperature which results from high speed, causes this kind of bearing to become loose and the soft part to wear at the ends?

Yes, to a certain extent, but the common practice is to have the bronze backing shorter than the white brass.

The Indiana Die Casting Company is now experimenting on a composition bearing metal to consist of 10 per cent. copper in combination with the other ingredients and discarding the bronze backing. The idea of the bronze backing naturally is to give the bearing strength and resiliency. In answer to a question as to the advisability of using this bronze backing, it was stated that one manufacturer has never used it and found the solid white brass bearings gave excellent service. A second, however, found that when there was any tendency to pound, the white brass bearing would break off at the edges.

The question was raised as to what the result of die casting was with reference to the grain and density of the metal as compared with the ingot. The density of the metal depends upon the casting temperature since this density in turn is influenced by the chilling effect of the die. The grain of the die casting, however, is more open, but harder than the ingot.

The common practice among automobile engineers is to use oil grooves in bearings and to put these grooves on the pressure side.

The question was raised as to the whole subject of bearings; if it is not entirely dependent on lubrication; if, with perfect lubrication—a perfect film of oil—if this would not take the pressure, absorb the friction, etc., but experiments have proven that even with perfect lubrication, when high speed is obtained the bearings undergo a very rapid increase in temperature, even in one case to the point where the connecting-rod ends become blue—all of which points out that the composition of the bearings must contend with this factor even if the lubrication is perfect.

The conclusion to be gathered on the composition of the anti-friction bearings was that the white brass die cast bearings, backed with a resilient metal such as bronze and provided with correctly spaced oil grooves, have so far proven the best.

Record Attendance at Detroit S. A. E.

DETROIT, MICH., Dec. 6—At the regular monthly meeting of the Detroit Section of the Society of Automobile Engineers, last night, at which the record number of sixty-eight was present, a paper by L. B. Brown and descriptive of a new Swiss slide valve motor was presented. It was productive of considerable discussion. Ferdinand Jehle also read a short paper on a new form of magnetic absorption dynamometer.

The new Swiss motor which was brought to this country by Mr. Brown and George Ratcliffe, of London, England, was designed by Martin Fischer, of Zurich, Switzerland. The Motor and Gear Improvement Company has undertaken its promotion in this country, and has it in an imported machine which is also built by Mr. Fischer. This particular engine has been put through some 11,000 miles of hard service and from this experience Messrs. Brown and Ratcliffe stated to the Detroit section of the society that they could give the information obtained by this actual road use of the engine, as well as results of a dynamometer test which was conducted on the Hudson Motor Car Company's testing block.

Want American Exhibits

Russian Show to Be Held in May—Big Field for Exporters—Military Trucks Needed

THE Emperor of Russia will inaugurate the International Automobile Exhibition at St. Petersburg on May , 1913. This project is organized by the Imperial Automobile Club of Russia under the patronage of the Czar and with the backing of the Imperial government. As an event of momentous national import it is being planned on a scale altogether unprecedented in that country.

The president of the Council of Ministers, Mr. Kokoftzeff, has assumed honorary presidency of the exhibition. It is the first exhibition of its kind in Russia to have enlisted direct support from the government authorities and the august patronage of the Czar of Russia.

It certainly is the first exhibition ever held in the Russian empire which avowedly aims to arouse popular interest in the American automobile industry and those allied therewith; in fact, where not only is there marked attention paid to prospective American exhibitors, but where American products are distinctly given official indorsement from the outset.

In his official invitation to the United States Department of State, George Backmeteff, the Russian Ambassador at Washington, expresses himself as follows:

"Considering the fact that the American type of the automobile is indicated for country use in Russia, adapting itself more than the machines of European construction to roads not macadamized, the Automobile Club of Russia is keenly interested in seeing the great American manufacturers of motors and automobiles exhibit their new models at St. Petersburg in the spring of 1913."

Addressing the automobile manufacturers at large Dr. W. Swetchine, aide-de-camp to the Emperor and vice-president of the I. A. C. of R., imparts the following interesting information about Russia:

"Russia was later than other countries to take up the automobile and it is only in the last few years that its use has become general. Our reliability trials of 1910, 1911 and 1912 for the Emperor's prize finally exploded the idea that the Russian roads are unsuitable for automobiles and showed that the country possesses a fine system of excellent highways. These trials also induced the rural population to take an interest in automobiling.

"We are convinced that the American cars should suit the Russian demand as there is a great similarity in the automobiling conditions of the two countries. Our vast grain-producing steppes, peopled with landowners and farmers, dependent altogether on horses for means of locomotion, should prove an excellent market for cars and especially for American cars, as in these districts it is noticed that the light and powerful American cars negotiate the sandy tracks quite satisfactorily when the heavier European car finds difficulty in getting through. Unfortunately, up to the present time, the Russian customer has had little opportunity of judging what a really good American car is as few American firms are represented here. We consider that this is the moment for the American automobile trade to take its just position in the Russian market and our exhibition offers them the means to do this quickly and conveniently. American exhibitors need not bother about the language question, as they will find numbers of Russians talking their language."

Perhaps one of the motives actuating the Russian authorities in evincing such marked and complimentary attention to prospective American exhibitors springs from their desire to dispel any erroneous impressions lodged in the mind of the average American about the alleged hostility of Russia towards this country on account of the abrogation of the treaty of 1831, which came as a result of the widespread agitation from anti-Russian sources. Some anxiety is entertained on this score by the promoters of the exhibition and should the American manufacturers decline to participate in this event it is reasonably certain that their motives will be misconstrued. This may prove disastrous for any prospects of a wholesale export of American cars to Russia.

There is no doubt, however, that the chief factor governing the attitude assumed by the Russians towards the American automobile manufacturer lies in the undoubted superiority of the American-made cars and particularly trucks over the European types, so far as Russian road conditions are concerned, which show a great similarity to those prevailing in this country. English, German, Belgian motors and cars have been developed along essentially different lines. They are a product of ideal road conditions. Some of the makes are superb specimens of engineering skill, but they are, none of them, calculated to withstand the wear and tear imposed by Russian country roads. European trucks are not especially adapted for interurban traffic because countries like England, Belgium and Germany are so

The Edwards-Knight Car

(*Continued from page* 1231.)

highest at X1 and lowest at X2. This arc Z is part of a circle described from the center K, which is the center of support of the forward end of the radius rod so that the line KX1 is a radius of this circle as also are the lines KX and KX2, making them all the same length so that there is not any equalizing of distance and consequently no sliding at the joints.

Further: The angle A1 in the rear joint equals the angle Y1 of the forward joint and similarly the angles A2 and Y2 are equal, a fact which explains the neutralizing of the acceleration and retardation of the joints twice in each revolution.

Radius rods have a ball-and-socket front-end support and ball rear-end support.

The torque rod, a tapered tubing, is doubly flexibly supported in front. Fig. 12 shows the ball-end stud carried in a cross-member of the frame and the similar end on the torque tube. The vertical tube containing them has four coil springs, one above and the other below, so that the utmost universal action is obtained. In action this torque member synchronizes with the propellershaft and radius rods in that the point M is midway between the front and rear universal joints, a fact which aids in preventing joint slippage.

The worm-driven rear axle is a Timken housing with a David Brown straight-type worm mounted underneath the bronze worm wheel. The axle housing is a standard type of Timken stamping with the differential expansion placed horizontally instead of vertically as in the bevel-driven axle. The wormshaft is carried fore and aft on special non-adjustable Timken rollers, their end-thrust merits eliminating other end-thrust bearings. The unit made up of the worm and wormwheel with differential is mounted in a steel casting hung in the under side of the axle stamping. There is a 4 to 1 reduction between worm and wheel. The axle is a floating type, and carries standard internal and external brakes.

The Lanchester rear springs, shown in Figs. 1 and 9, are inverted semi-elliptics supported in their center to the frame through a trunnion, shackled to the frame at their fronts, and carried underneath the axle at their rear, where they are not shackled but bear upon a roller, thus allowing for free back-and-forward motion. The spring is 54 inches long.

In the running gear the double-dropped frame gives a low body, the drop being 3 inches at the dash and 7 inches in advance of the axle. Tires are 36 by 4.5 inches all around.

thickly honeycombed by a network of railways as to obviate all necessity for truck-hauling of goods or passengers. They have never experienced any lack of railroad communication between any two points, wherever conditions would in the least warrant the construction of a railroad. Hence the use of the motor truck has been confined almost exclusively to city delivery service and the motor and truck manufacturing plants have been adapted for production along these lines.

Compared with the American machine, the average European car or truck is encumbered with too many parts and much too delicate adjustments of the same. They have been thoroughly tested in Russia and found unable to cope with the rough-and-ready service demanded of them.

The Russian military authorities are particularly interested in the American motor truck in view of the impending reorganization of the entire army transport service. The following is the list of special types of trucks in which the Russian military authorities are particularly interested:

Motor trucks fitted for carrying military stores, motor trucks fitted for transporting aeroplanes, motor trucks fitted for radio-telegraph stations, motor cars fitted with radiography stations, searchlight motor cars, field kitchen motor cars, freight wagons fitted for smithy and fitting workshop, tank motor trucks, motor cars with armored body for quick-firing guns, sanitary motor cars for carrying wounded and sick, motor cars fitted for being used as field surgical operation rooms, freight cars with appliances for receiving field stretchers with wounded, motor cars with an unarmored gun for firing at aerial craft, motor fore-carriages for fortress artillery, military telegraph motor cars, power plant cars, light motor cars for scouting and communication service, appliances for enabling motor cars to drive through moving sand, tractor cars, 70-80 horsepower, with three trailers for carrying 30.4 centimeter mortars, motor cars with 90 centimeter projectors, motor cars with cranes for lifting guns and various heavy loads when going up hill on steep slopes, and motor cars with radio-telegraph stations.

All the exhibits will be divided in twelve sections as follows:

Automobiles, complete, for sport, touring and city use; chassis for same. Only motor and chassis constructing firms will be admitted in this class, under obligation to exhibit but automobiles and chassis of their own manufacture, while the bodies need not necessarily be of their own construction.

Passenger-carrying parts of automobiles, car bodies and materials entering the construction of the same; tonneaus exhibited separately or mounted on chassis, without mention, however, of the chassis makers.

Exhibits bearing direct relation to military automobiling.

Automobiles for fire companies, ambulances and other specific purposes.

Motor trucks, vans and wagons for various industrial, commercial, public service and agricultural purposes; railroad cars and trains driven by combustion motors; auto buses and automobile sledges.

Combustion motors for automobiles and for industrial and agricultural purposes.

Motor cycles, bicycles; parts and accessories for the same.

Motor boats, parts and equipment for same; bodies, motors, propellers, etc.

Tires and rims for automobiles, motor cycles and bicycles; special tire-mounting contrivances, etc. Overhauling and repair outfits; detachable and demountable rims, etc.

Machinery, lathes and other plant for the equipment of automobile factories.

Automobile accessories, head and tail-lights, searchlights, sirens, horns, candles, carbureters, lubricating devices, motor trimmings, cocks and valves; automobile attire and objects of necessity or convenience for motorists, cyclists and tourists. Bibliography, photography, periodicals, drawings.

Fuel: benzine, gasoline, alcohol, crude oil, etc. Lubricants: oils, greases and mixtures. Illuminants for lamps and searchlights. Special tanking for oils, benzine, etc.

Street Cleaners Engineers

Paris Examination for Post on Motor Squad Severe—Automobile Racing for Christmas in Mexico

PARIS, Nov. 27—There is no room for green hands in the motor street sweeping service of the city of Paris. The government driving license, delivered after a practical examination, is the least important of the requirements, for while it is considered necessary that the operator should be able to drive, mechanical skill is considered of still greater importance. In order to be admitted to the ranks of the motor street sweepers all applicants must successfully pass the following tests: Forge a small part according to drawing supplied; solder; adjust and assemble various forged parts; bearings, pulleys, flywheels, crankshafts, transmissions, gearsets, ball bearings, etc.; case hardening, brazing, soldering, the making of pipe joints for automobiles. Complete dismounting of a gasoline motor, assembling same and tuning up; fitting various kinds of lubricators, also cooling systems by pump and thermo-syphon and with and without fan; fitting and regulating a carbureter for gasoline or benzol; fitting and regulating an ignition system by magneto or storage batteries; fitting and regulating a clutch; change certain parts in a gearset and a differential; assemble and regulate brakes and steering gear. Finally, the candidates must find the causes of a breakdown in a motor and remedy them and also show their ability to verify the condition of a machine before taking it out.

Arrangements have been made by the Paris municipality for the gradual displacement of all horse-drawn vehicles for street sweeping and watering.

Mexicans Prepare for Xmas Race

CITY OF MEXICO, MEXICO, Dec. 7—The automobile devotees in this city, as well as in other parts of Mexico, are much interested in the City of Mexico-Pueblo road race that is to be run on Christmas day. This will be the fourth annual running of this race and the event is arousing more interest this year than ever before. The race will be from this city to Pueblo and return. The committee in charge of the event has decided not to divide the race into a contest beginning one day and finishing the next, but the round trip of the racing cars will be made in a single day.

Prospects are bright for a larger entry list than ever before and it is believed that every prominent car in the country will be represented.

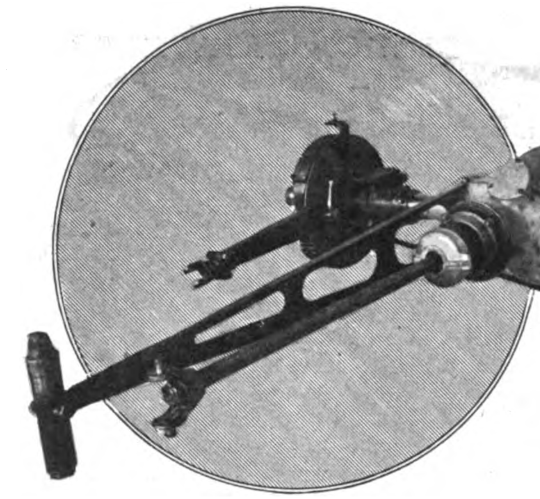
The cars will be divided into three classes, the same as last year, the most powerful cars running in class A, which is for automobiles of over 350 cubic inches cylinder capacity. Class B for cars of between 230 and 350 cubic inches cylinder capacity and the small class C, for cars of less than 230 cubic inches cylinder capacity.

The automobiles in class C will run only as far as Calpulalpam and return, thus making the round trip for this class 160 kilometers, as compared with 320 kilometers for classes A and B. Class C cars will be the last to leave Mexico and the first to return. From the time the last car leaves in the morning until the first returns in the afternoon there will be an interval of, probably, not more than 3 hours.

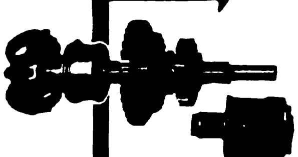
The position of the cars will be published at intervals on a bulletin board in front of the grandstand, at San Lazaro, so that the public can follow the progress of the race from start to finish.

The race is being arranged under the auspices of *El Automovil en Mexico* and *El Imparcial*.

Locomobile Little Six Introduced for 1913



Mounting of torque rod and rear axle



Part view of Locomobile gearset

ELEMENTAL design has undergone little change in the Locomobile line for 1913, but many minor refinements and changes in dimensions have been made. Of chief interest, however, is the little six, introduced for this season. It has been designed to meet the demand for six-cylinder cars of moderate cylinder dimensions. Besides the small six there is a larger six-cylinder car and a four-cylinder. The maker's horsepower ratings in all these models, which are known as the M, R and L respectively, are far below the horsepowers actually developed. In order to show the performances a horsepower and torque curve plotted on a basis of revolutions per minute is given in Fig. 6. The ratings of the models M, R and L are given in the table below. The bore and stroke are also given and it will be noted that the six-cylinder motors have all a larger stroke-bore ratio than has the four-cylinder motor. The dimensions are:

Model	Cylinders	Bore	Stroke	Rated H.P.
R	6	4.50 inches	5.5 inches	48
M	6	4.25 "	5.0 "	38
L	4	4.50 "	4.5 "	30

The principal changes to be noted are in the motor dimensions on the larger six-cylinder car. The stroke has been increased to 5.5 inches and this has, of course, necessitated changes in the connecting rod and cylinder lengths. An increase in the horsepower of the motor has been the effect of this change, the motor showing 82 horsepower at 1,800 revolutions per minute. The horsepower and torque curves are given in Fig. 6 and show the performance. Other changes which may be remarked are the increased valve sizes, changes in the form of the inlet and exhaust passages and a new design of Locomobile carbureter. The latter differs from the former Locomobile product by its longer throat and the use of both hot-air and hot-water jackets. A six magnet magneto takes the place of the former type while refinements in the oiling system of the 1913 cars consist of a shift of the oiling pump drive from the exhaust to the inlet side of the motor. The oil-level pet cock has been placed on the left side of the reservoir in the motor base. A new type of main bearing oil lead has been fitted to give an increased flow of the lubricant and also to give a more direct flow. Changes in the cooling system consist in the enlargement of the radiator and pump as well as the waterjackets. The installation of the generator for the electric lighting system has necessitated a change in the water inlet manifold. Increases in the size of parts in the transmission units have been necessitated by the larger power which they are compelled to carry. Tires are now carried at the rear on brackets which are a unit with the frame of the car and the running boards have been left clear to give a clean appearance. A motor tire pump forms part of the 1913 equipment.

As the practice is the same in the design and construction of both sixes, a description of the larger will cover the general design. The exterior appearance of the motor is shown in Figs. 1 and 2, giving the left and right sides respectively. It will be noted that the cylinders are cast in pairs and are mounted with a space between, giving a hint of large bearing space. In the sectional views given in Fig. 4, an idea of the transverse and longitudinal arrangements may be gained. It will be seen that the cylinders are T-shaped castings. They are composed of the standard grey cylinder iron and have the side waterjackets integral and the upper part separate. The 5 1-2 inch long pistons are also composed of grey iron and are fitted with five rings, four of which are located above the wristpin. A ring which serves as an oil distributer is at the bottom. The wristpins are located at the centers of the pistons and are held in place by two studs which are locked by a wire passing across their inner extremities. The material in the wristpin is chrome nickel steel case-hardened and fitted with a bronze bushing for the upper connecting-rod bearing. The diameter of the wristpin is 7-8 inch on the large six, which may be taken as a standard to show the proportions which exist throughout Locomobile design and which car is specifically described in the following.

The connecting-rods are 11 7-8 inches in length and are composed of chrome-nickel steel. The big end bearings on the big six are 2 1-4 inches in length and on the little six are 2 inches. The seven-bearing crankshafts have large bearings between the cylinder blocks and smaller bearings between cylinders forming part of the same casting. The smaller main bearings on the big

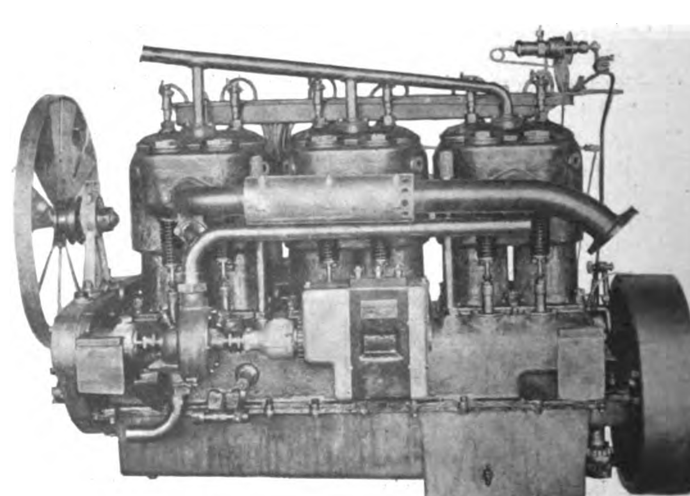


Fig. 1—Left side of model R Locomobile motor

six are 1 7-8 inches and those between blocks are 2 1-2 inches. The crankshaft is made of chrome nickel steel and being supported on the seven bearings lined with Parsons white metal bushings gives a stiff and lasting installation.

The valve action is clearly illustrated in Fig. 4. As will be noted, the cams act directly upon the roller followers giving a minimum of linkage with silent and quick action. The tappet guides are lengthened out to prevent a troublesome leakage of oil around this part of the motor. No covers are placed over the valve action, silence being secured by a close adjustment between the tappet and valve stem. A cold clearance of .003 inch is allowed at this point. The cams are cut integrally with the camshaft and hence have no tendency to become loose. The camshaft is driven through the spiral timing set. The Locomobile company has gone over to the spiral gear and has secured silence by eliminating back lash. The limit to which each gear is finished is within .00025 inch, and noise from this quarter is eliminated. The pitch of the gears in the model M is 11 and in the model R 12.

The cooling circulation is attended to by a centrifugal pump located on the right side of the motor. It is shown in Fig. 1, near the forward end of the motor and is operated off the same shaft as the generator. As may be seen from this view the water intake manifold has been lifted above the generator and runs back just below the exhaust pipe. Cooling is further aided by a six-plated aluminum fan mounted on a bracket fixed to the timing gear case. The radiator is of the cellular type and as has been stated, is made larger for this season.

The ignition system is by the high-tension dual consisting of magneto, storage batteries, and coil. The storage battery is used independently for ignition, and consists of three cells providing a current of 6 volts. This same system is used on all three models and is independent of the lighting and starting. The remainder of the electrical equipment is used for the lighting system. It consists of the Adlake dynamo battery and regulator. The dynamo operates when the motor has reached a certain speed and supplies the current for the lights at that time. The battery takes care of the lights while the dynamo is not in operation. The regulator maintains a constant voltage and protects the lights and filaments. This system is protected from the effects of overload by a fuse system so arranged that they may be easily reached on the removal of a cover plate. The electric horn is also protected by a 10-ampere fuse.

Among the innovations for the season of 1913 is the carbureter used on the little and big six-cylinder cars. This carbureter is of the eccentric float type and is heated by either hot air or hot water. The air valve of this carbureter is distinctive. It is provided with two springs, the smaller and stiffer of which operates only at comparatively only high engine speeds. At lower speed the amount of opening is controlled by the larger and weaker spring.

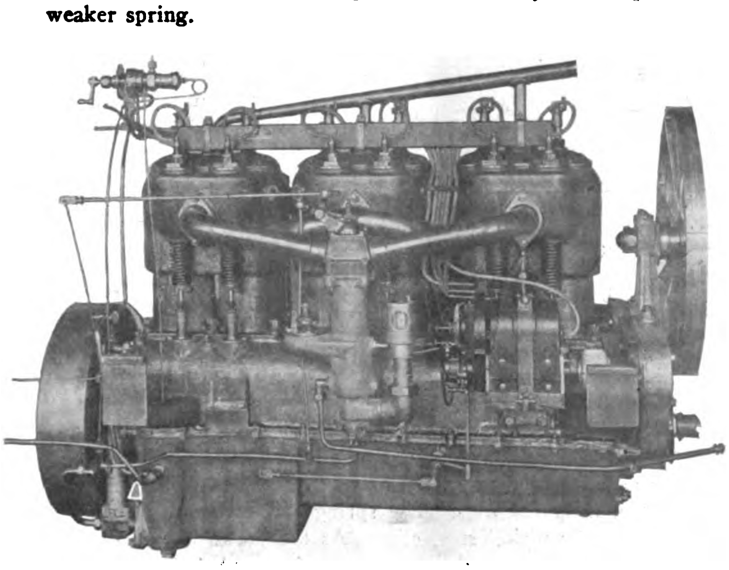

Fig. 2—Right side of model R Locomobile motor

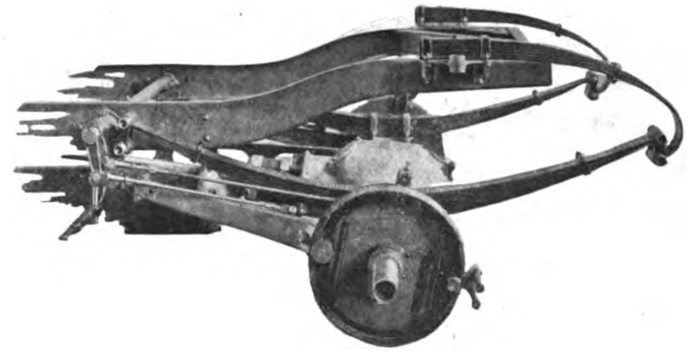

Fig. 3—Locomobile suspension and brake assembly

Oiling is accomplished by combination of the force-feed and splash systems. The crankcase is made in two parts, the lower forming the oil reservoir and containing the troughs necessary to the splash, and the upper which is composed of manganese bronze, carrying and supporting crankshaft and camshaft bearings. The oil capacities for the models M, R, and L are 2.25, 3.5 and 2.5 gallons respectively. The main reservoir on the 38 and 48 horsepower motors is carried at the rear of the crankcase casting. Fom here it is lifted by the gear pump driven off the inlet camshaft to a series of leads through the bronze part of the crankcase to each main bearing. The leads are cored through the centers of the web or bridge carrying the main crankshaft bearing. A hole drilled in the main bearing bushing registers during a portion of each revolution with the opening at the end of the oil lead. During this time oil is forced under the pressure of the pump, against the centrifugal force at this point, and is forced to enter the drilled crankshaft. Following the drilled duct through the crankshaft the oil is led to the lower connecting rod bearings and supplies these copiously with lubricant. Excess oil drains to the splash troughs, located below each cylinder and keeps these constantly filled. A test made on the oil pump used in the Model M car is shown in Fig. 7. As will be noted the output between 100 and 1,000 revolutions per minute increases directly as the speed of rotation. The output of the pump is such that it will at all times furnish a greater supply of oil than is needed, so that there will be an overflow from the splash troughs back to the reservoir in the crankcase. The course of this overflow may be noted in the longitudinal section given in Fig. 4. In order to prevent any bad effects which might occur from recirculating the oil, wire gauze screens are placed between the reservoir and the circulating pump.

The starting system is the Disco acetylene. The acetylene tank which is carried for use with this starter has no other purpose, as all the lighting throughout the car is taken care of by electricity.

Forty-three hardened saw steel disks are used in the clutch, which is of the conventional multiple-disk type housed within the flywheel. The clutch on the four-cylinder model is a leather-faced cone. The multiple disks on the two six-cylinder cars run in a bath of engine oil and kerosene in equal parts. The clutch disk retainer, or in other words the driven member of the clutch is supported upon a double row of ball bearings at the motor end and upon a single large ball bearing at the other end. A feature of the clutch which is worthy of comment is the fact that it can be removed from the car without interfering with any other member and any repairs necessary can be made in a correspondingly short time and hence with less expense.

Between the clutch and the gearset is a universal joint. The gearset which is standard for the Locomobile line has four forward speeds and reverse. The backlash on these gears is limited to .001 inch and the grinding work is done to limits of .00025. This gives a silent and long wearing gear. Ball bearings are used throughout and the lubricant to be used is a light gear compound. The capacity of the gearset is 20 1-2 pounds of grease.

A chrome nickel steel propeller shaft transmits the power to the rear axle. At each end there is a universal joint. The shaft is not enclosed in a torque tube but there is a deep strut as shown

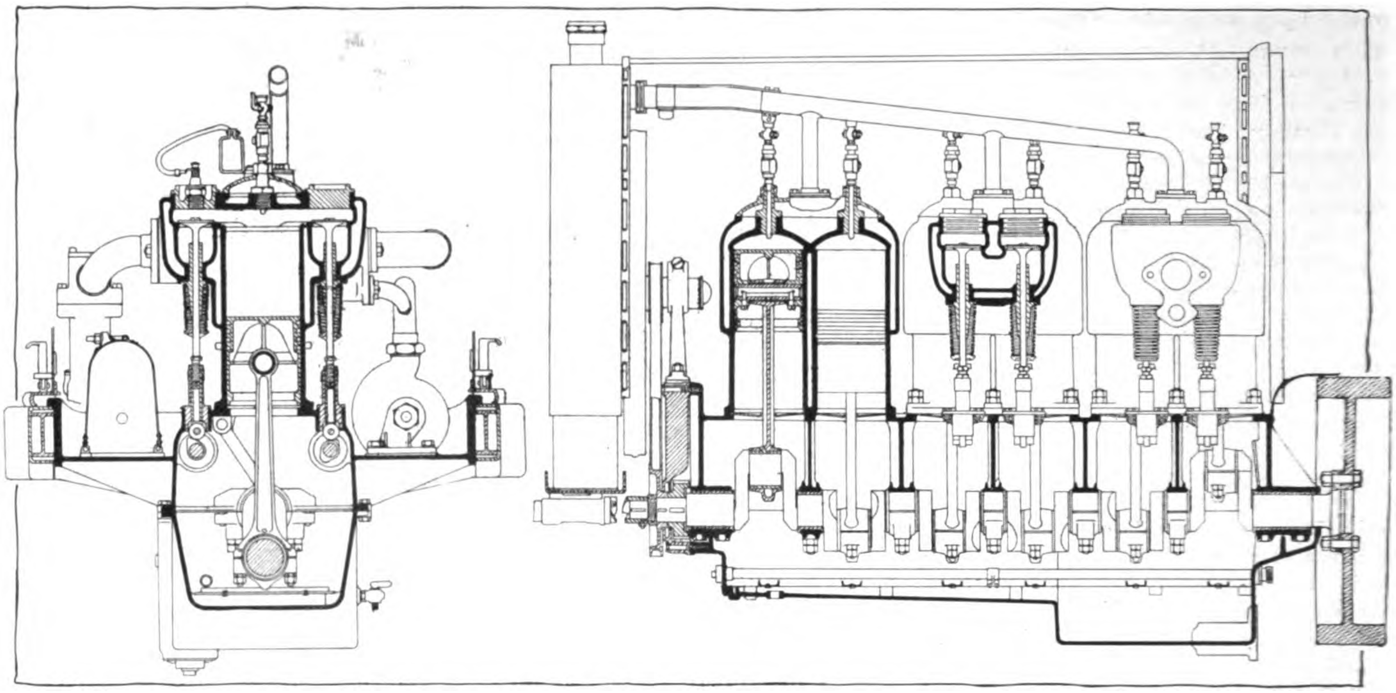

Fig. 4—Transverse and longitudinal cross-sections of model M Locomobile motors, showing details of construction

at the head of this description, which is bolted rigidly to the rear axle and flexibly to a cross member of the frame. This torque member tapers from its rear connection to the forward point of suspension giving it a triangular shape. To lighten it without materially cutting down its strength or rigidity the web of the channel is left open as shown in the illustration. The material of which this member is composed is pressed steel. Two radius rods take up the drive allowing the rear springs to be free as far as the drive is concerned and leaving their only duty the easing of the suspension of the car. The radius rods are steel castings and are bracketed to the frame.

The rear axle is bevel driven. Both the pinion and the gear are adjustable and changes can readily be made in the mesh of these two gears. Fig. 8 shows the rear axle housing with the cover plate removed allowing of an inspection of the gears. A smaller cover plate over the differential housing allows of a view of the pinion and large bevel gear. The adjustments on the pinion can be made through this opening while the adjustments on the bevel gear can be made through the opening left by the removal of the rear cover plate. The rear axle is built up of tubes which are forced into place under 9 tons hydraulic pressure. In addition to this the tubes are riveted. These tubes carry the load of the car as the axle is of the floating type.

Both sets of brakes are carried on the rear wheels. All the braking stress is taken through the radius rods, none of it is felt by the torque rod or springs. The dimensions of the brakes are 14 inches diameter and 2 inches face for the expanding and 14 7-16 inches diameter and 3 inches face for the contracting. Both sets of brakes are lined with asbestos fabric. The brake adjustments are made by right and left threaded nuts on the emergency brake and by wing nuts on the service brakes. A view of the brakes, radius rod and spring suspension is given in Fig. 3. An equalizing bar is placed across the frame.

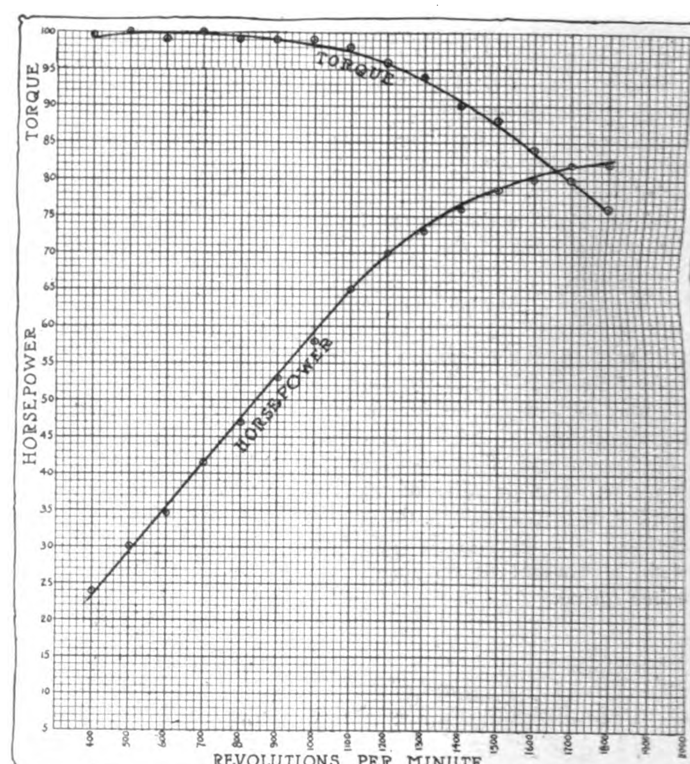

Fig. 6—Horsepower and torque curve of model R motor

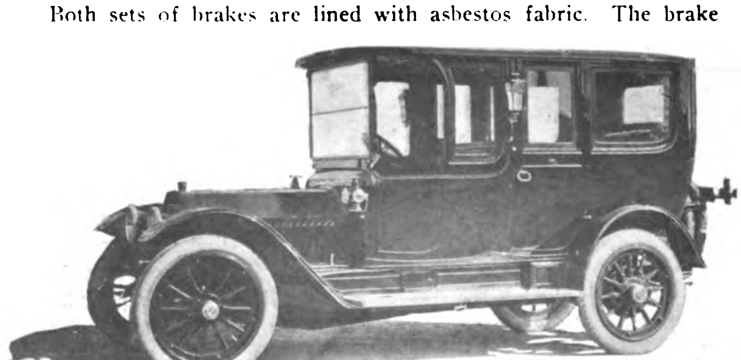

Fig. 5—Six-cylinder Locomobile with limousine body

Semi-elliptic springs are used in front and three-quarter elliptic in the rear. The method of mounting these is shown in Fig. 3. There are ten leaves in the rear springs while for the heavier bodies such as the limousine, the number of leaves is increased. The spring clips used to fix the rear springs to the rear axle are nickel steel drop forgings. The spring connection at the front is also made by nickel steel clips. As the front axle is driven through the spring they are made extra heavy and the heads of the clip bolts are also upset so as to preclude the possibility of losing one of the clips. The front axle is of I-beam section, with a drop at the center. The spring pads are integral with the upper flange. This axle is drop-forged from a one-piece nickel steel bar. A heavy dowel pin passes through the center of the spring and into the front axle to stiffen the construction against side motion. Tensile strength of front axle is 87,000 pounds.

The frame is a pressed steel channel bar, 4.5 inches in depth and with a flange ranging between 1.5 and 3 inches in width. The entire bar is pressed from 3-16 inch stock.

Twelve-spoke wood artillery wheels are used throughout. These wheels are all fitted with quick detachable demountable rims. The tire sizes differ for front and rear on the big six and for the three models are as follows:

Model	Front	Rear
M	36x4.5 inches	37x5 inches
R	36x4.5 "	36x4.5 "
L	34x4.5 "	34x4.5 "

Timken roller bearings are used for the front wheels. Roller bearings are also used on the steering gear which is of the worm and full gear type. The worm and gear are so arranged that six adjustments for wear are possible by removing the steering lever and turning a hexagonal nut. This brings a new portion of the gear in mesh with the worm and takes up the lost motion which occurs after a long period of use. Both the worm and the gear are case-hardened and if properly lubricated should not require adjustment for a long time. The roller bearings upon which the steering mechanism is carried are adjustable and wear is not likely to occur at that point.

A refinement incorporated on the 1913 Locomobiles is the cast aluminum cowl which is made a unit with the dash by bolting it

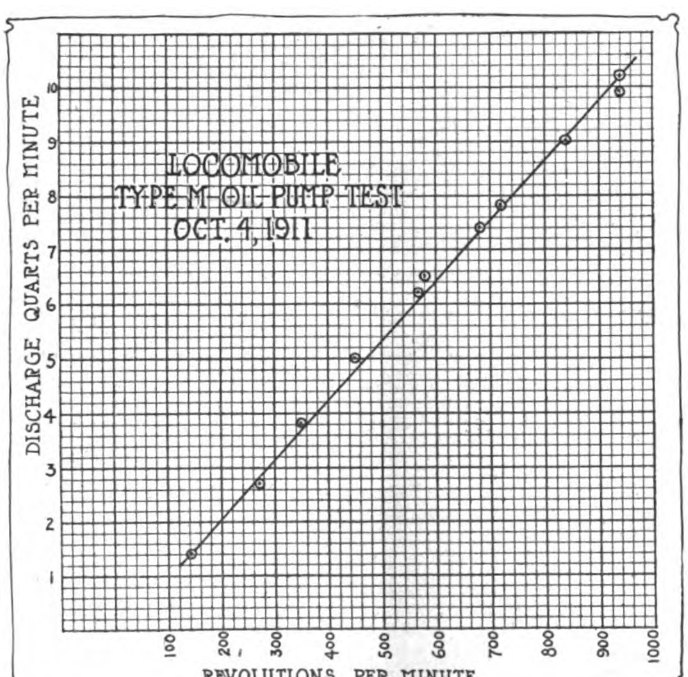

Fig. 7—Curve showing test results of model M oil pump

to the body sills. This silences body squeaks between the cowl and the dash.

Between the body and the frame is a layer of woven cotton belting material while the doors close against rubber blocks which silence their action and eliminate rattles. The drop-forged rear tire brackets are made a unit with the frame of the car so that there is a great amount of extra strength in these parts and they are not apt to shake loose. A refinement which may be mentioned is that the exhaust is carried out behind the car and is not allowed to escape beneath it. The muffler is very silent and is made up of a series of concentric perforated tubes, the perforations are at opposite ends of the tubes.

The 1913 cars are equipped with a single cylinder air com-

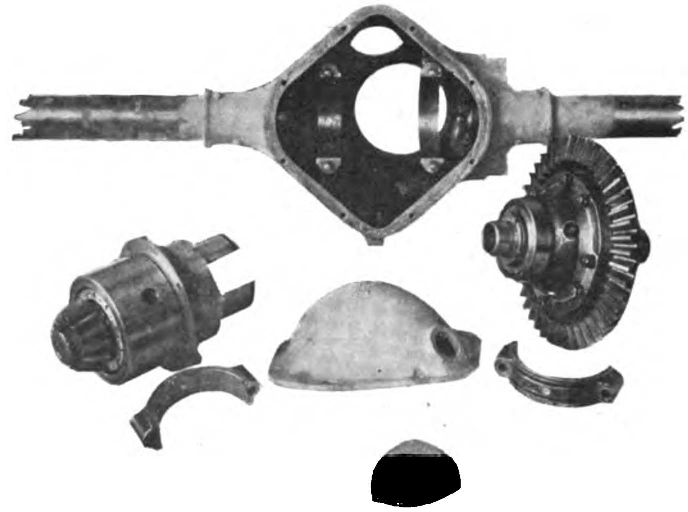

Fig. 8—Locomobile rear axle unit disassembled in parts

pressor, having a bore of 2.5 inches, and a stroke of 2.5 inches. It is mounted on an extension of the front end of the transmission counter shaft, and driven by means of jaw clutches, which can be thrown in and out of engagement by a T-handle located on the left side of the car, and reached by opening a door in the running-board side shield. By drawing handle outward about 3-16 of an inch, advancing one notch to the left in a serrated segment and releasing jaw, clutches are interlocked, and pump is ready for use.

Air is drawn into cylinder through holes drilled around same below radiating fins. Foreign matter is excluded by means of a removable screen. On the upper stroke of the piston the air is forced out of the cylinder by unseating a flat valve into a small tank placed at the right of the air compressor, and mounted in front of the transmission carrying channel. The purpose of this tank is to overcome the pulsation of the pump only, and not to act as a reservoir.

By means of a two-way fitting, air is drawn out of the tank through a delivery tube leading to a fitting which projects through the left side member of the frame adjacent to the T-handle mentioned above. One end of the tire hose is screwed on to this fitting when tires are to be inflated. The location of the two-way fitting on the tank is such that any sediment or oil falls to the bottom of the tank, and is not drawn out through the delivery tube. With the motor running at normal speed the air compressor will inflate a 37 by 5 inch tire to 90 pounds pressure in about two minutes.

—

THE MOST EFFICIENT rubber tire is naturally the tire that will roll along and offer the least resistance to rolling. In rolling over the relatively hard road surfaces the softness of the rubber allows it to spread, giving more surface in contact with the road; as against this the steel tire retains its shape, making an indentation in the road as it rolls along. As the composition of the road is not as efficient a spring as the rubber tire, the road resistance is naturally higher.

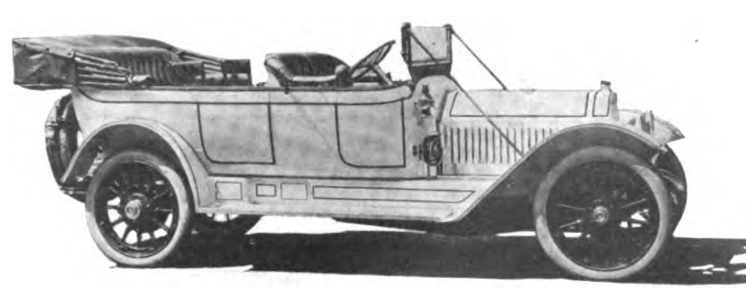

Fig. 9—Seven-passenger touring body on 1913 Locomobile

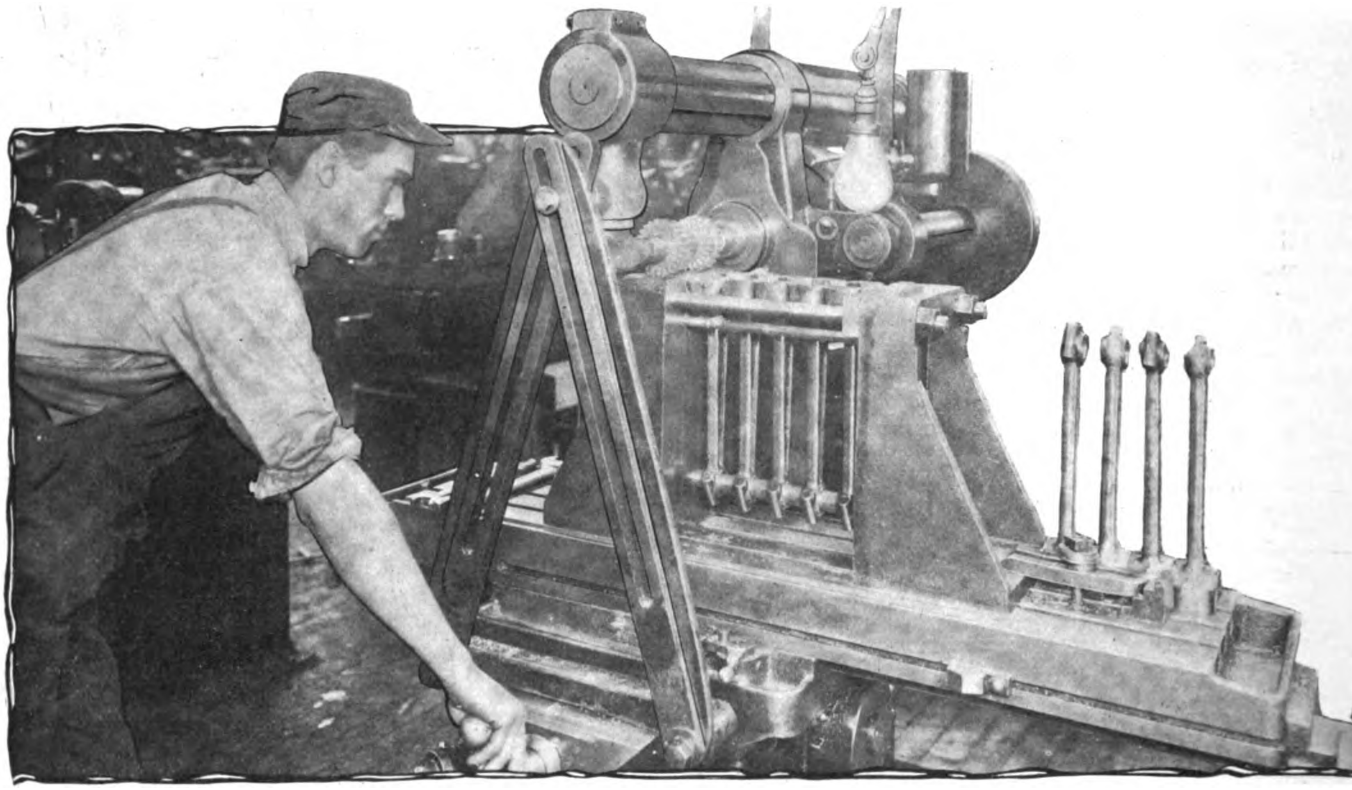

Gang milling machine for milling connecting-rods in use at the factory of the White Company, Cleveland, O.

AT the White factory the connecting-rods are turned out in quantities. That is to say, production in quantity is possible with quality. This is accomplished by the use of machines which do several things at a time. They are called gang machines because the tools are grouped together in the same manner as a gang of men. In the above illustration one of the gang milling machines is shown at work. It is milling the big ends of five connecting-rods. It is doing this work in the space of time generally required to do two. It is saving the White company time and therefore money and is one of the instruments that enables the concern to put a low price on a high quality product. It is in machines of this kind that quantity production is given its true value. One man takes care of this machine. While it is doing the milling work on one set of five rods the workman is setting up the next set. It takes a half hour to finish a set of five and the machine can work steadily all day turning out in the neighborhood of a hundred in a working day. Naturally, such a machine as this, though expensive, pays for itself in a short time.

ATWATER-KENT Adds Equipment—The Atwater-Kent Manufacturing Company, Wayne Junction, Pa., has recently installed a considerable amount of new machinery to take care of the machine work on the new model K Unisparker. The added equipment will increase the capacity of the plant to a marked degree.

Briggs-Detroiter Adds—The Briggs-Detroiter Company, Detroit, Mich., has acquired a tract of 3 acres adjoining its plant, to provide for future extensions.

Maritime Plant Nearly Completed—The Maritime Motor Car Company has its factory at Coldbrook, N. B., far advanced toward completion.

Willard's Four Plants—The Willard Storage Battery Company, Cleveland, O., has added to its plant, No. 1, three more buildings, affording 50,000 square feet of additional manufacturing space.

Interstate Tire Leases Land—The Interstate Automobile Tire & Rubber Company, Atlanta, Ga., has leased 33 acres and four buildings and will manufacture rubber tires and automobile accessories.

Precision Die-Casting Moves—The Precision Die-Casting Company, Syracuse, N. Y., has moved into its new office and plant which was formerly the factory of the E. C. Stearns Manufacturing Company.

Premier's Additions—The Premier Motor Manufacturing Company, Indianapolis, Ind., will build two additions to its plant. The new structures will be two stories high, one 40 feet by 140 feet, the other 48 feet by 140 feet.

Morris Purchases Factory—A. W. Morris, Philadelphia, Pa., has incorporated under the name of the Morris Manufacturing Company, and has negotiated for the purchase of the Wetherill Finished Casting Company's factory.

Firestone's New Building—The Firestone Tire 7 Rubber Company, Buffalo, N. Y., will erect a new four-story and basement building containing 30,000 square feet of space, which will be ready for occupancy about January 1, 1913.

Paige Building—The Paige Auto Hoist Company, Grand Rapids, Mich., will build a factory on a site recently purchased in that city. The company will manufacture a device for lifting the weight of an automobile from its tires when the car is not in use.

Will Increase Plant—Building plants and operations are under way at the Baker Motor Vehicle Company, Cleveland, O., which will increase the size of the factory by about 30 per cent. The first of the new buildings will be occupied by the truck department.

Kline Plant Opened—The Kline Motor Car Company recently opened its Richmond, Va., plant. It will give employment to approximately 750 skilled workmen, and will have a capacity of 2,000 machines a year. The new plant was built at a cost of $100,000.

Fiat Head Inspects Factory—Chevalier Giovanni Agnelli recently arrived on the Mauretania on an inspection trip to the Fiat factory at Poughkeepsie, N. Y. He will be accompanied by E. R. Hollander, president of the Fiat Motor Sales Company, New York City.

Federal Arranging New Plant—The Federal Motors Company, Indianapolis, Ind., is making arrangements to erect a new plant, which will consist of a one-story building, costing approximately $150,000, exclusive of machinery. The structure is to be of brick and steel.

Brockway Building—The Brockway Motor Company, Cortland, N. Y., is taking bids for the construction of a manufacturing plant 40 feet by 268 feet, one story, of concrete block construction. A considerable amount of machinery equipment will be installed.

Students Inspect Rambler Factory—Fifty students of the senior class of engineering from the University of Wisconsin visited the Rambler factory, Kenosha, Wis., recently and made a close inspection of the unit gasoline and electric motor with which the 1913 Rambler is equipped.

Hudson Adds Space—Hard on the heels of the recent announcement that the Hudson Motor Car Company, Detroit, Mich., was to erect a large new factory building, comes the news of still another. A second addition to the plant is to be built, which will result in the doubling of the factory in a year.

Everitt's Branch Factory—A branch factory of the Everitt Motor Company, Detroit, Mich., will be established at Windsor, Ont. The plant will be erected by the Tudhope Automobile Manufacturing Company. It will cost $100,000 and will occupy a 10-acre site. Building operations will commence in April of next year.

Palmer-Moore Buys—The large plant owned by the Syracuse Stove Company, Syracuse, N. Y., has been sold to the Palmer-Moore Company, that city, which will manufacture motor trucks. A 1,500-pound delivery wagon will be manufactured. According to the company's plans, there will be 150 hands employed and 200 trucks will be put out the first six months of 1913.

Packard Enlarges—To expedite the manufacture of the 38 and future models, the Packard plant, Detroit, Mich., already comprising 37 acres of floor-space, is being enlarged. Three buildings, constructed entirely of glass, concrete and steel, have been erected to conform to the Packard factory's system of shop units. The additions are practically complete and will be ready for occupancy by January 1.

Palmer's Ecorse Factory—The Palmer Motor Car Company will occupy the large automobile plant being constructed at Ecorse, Mich. It is expected that manufacturing in the new plant will be started about the first of the year. A large force of workmen is pushing the construction on as rapidly as possible. The new plant has a frontage of 358 feet on the main lines of all the railroads entering Detroit from the south.

Tire Plant Enlarged—The Goodyear Tire & Rubber Company, Akron, O., is adding three buildings. The company has acquired the entire property of the Akron branch of the Great Western Cereal Company. When the additions are entirely completed, the company will have a capacity of 8,000 tires a day. The three latest additions will aggregate 335,300 square feet of floor-space. This brings the total up to 1,935,300 square feet.

Shows, Conventions, Etc.

Factory of the Atwater-Kent Manufacturing Company, Wayne Junction, Pa. Mr. Atwater-Kent's house and garage at the left

Gathering of the American Automobile Association at its annual Banquet during the recent session of the organization in Chicago

WANT Automobile Laws Amended—A delegation representing different automobile clubs in Canada waited on the provincial treasurer recently in Quebec, Que., asking for certain amendments in the law governing automobiles. Among the important amendments asked is the increase of the speed limit to 15 miles in the cities and to 20 in the country. It is also asked that the distance for judging the speed of an automobile should not be less than .125 mile in cities and .5 mile in the country.

National Hartford Equipped—The National car is now being equipped with Truffault-Hartford shock absorbers.

Berry Apointed Manager—The H. W. Johns-Manville Company, New York, has appointed C. S. Berry manager of its Atlanta, Ga., office.

Overland Branches Established—The Overland Automobile Company, Phoenix, Ariz., has opened branches in Tucson, Yuma and Kingman, that state.

Grant Leaves Racing Game—Harry Grant has joined the staff of the Jackson's Boston, Mass., branch. Mr. Grant says he has left the racing game.

Holley at Foreign Shows—Holley Brothers Company, Detroit, Mich, manufacturer of the Holley carbureter, will exhibit at the Olympia and Paris shows.

Grossman Sails—Emil Grossman has sailed for Europe to attend the automobile Salon at Paris, and the Olympia Show at London. He will return in time for the Madison Square Garden Show.

Holley Coventry Branch—Holley Brothers Company, Detroit, Mich., manufacturers of the Holley carbureter, has established a branch in England at 46 Northumberland Road, Coventry.

Duncan with U. S. Motors—Announcement is made of the appointment of Henry M. Duncan as supervisor of the eastern district of the United States Motor Company in place of W. F. Smith, resigned.

Mesker Resigns—L. H. Mesker, manager of the St. Louis, Mo., branch of Manning, Maxwell & Moore, Inc., has resigned his position to be connected after January 1 with the Ferro Machine & Foundry Company, Cleveland, O.

Montreal's Show—Two hundred and fifty automobiles, 210 of the pleasure type and 40 trucks, will be on exhibition at the coming annual automobile show, to be held under the auspices of the Automobile Club of Canada, Montreal, Que.

Matheson Branch Closes—The Matheson Automobile Company has closed its branch in Boston, Mass., after an existence of about one year. The branch was taken over from an agency conducted by Roy Faye, who had the car for some years.

Minneapolis Club Elects—The annual election of the Minneapolis, Minn., club officers was held recently, the following officers being elected: President, H. J. Clark; vice-presidents, W. P. Devereux and T. N. Kenyon; secretary, G. Roy Hill; treasurer, J. H. Prior.

Canadian Good Roads Movement—The work of raising $100,000 to build a tourist road between Ottawa, Ont., and Prescott, will be commenced at once, according to a decision reached at a recent general meeting of the Ottawa Valley Motor Car Association.

By Way of Correction—In the November 14, 1912, issue of THE AUTOMOBILE, under the heading New Agencies Established During the Week, the address of Brownell & Burt, handling the Federal truck, should have been given as Taunton, Mass., and that of H. Baxter, also Federal truck agents, as Springfield, Mass.

Marmon Reaches Los Angeles—The Marmon hundred century car reached Los Angeles, Cal., recently. The car, because of its schedule to cover 10,000 miles in 100 running days, was slightly ahead of its schedule when it reached Los Angeles, having covered the 2,828 miles in 27 days. The return trip to Indianapolis, Ind., will be begun next spring.

Cuyahoga County Leads—The annual report of Registrar J. A. Shearer of the State Automobile Department, Ohio, on the number of chauffeurs in that state, shows some interesting figures. Cuyahoga County leads with 1,770, while Hamilton is second with 1,322 and Franklin third with 772. Vinton is the only county appearing without a licensed chauffeur.

Marker's Road Plans—State Highway Commissioner J. M. Marker, Ohio, has made his plans known in reference to road building in Ohio for 1913. He will request that the legislature appropriate $1,700,000, which would give every one of the 88 counties in the state $20,000 each. He will ask the legislature to provide for a one-half mill levy on good roads construction during 1914.

Opens Branch House—The Riddell Automobile Company, Des Moines, Ia., has opened a branch house at Oskaloosa, Ia.

Acquires Fire Apparatus—Grand Rapids, Mich., has just placed into service a combination White hose and chemical wagon.

Overland Cars for Polo—President John Willys, of the Willys-Overland Company, Toledo, Ohio, has become so interested in the lately invented game of automobile polo that he is discussing seriously the construction of Overland cars with planetary system gears for use in the game.

Hunting by Automobile—Hunting by automobile has become a favorite sport in the ranch region of South Texas. It is now a common practice for parties of sportsmen to take a spin over the ranch roads into the heart of the mesquite and wilderness and return with a load of wild game. The cars are also convenient for hauling in the game. It is not an uncommon thing to witness the arrival of parties with their cars literally loaded down with the fruits of their marksmanship. The accompanying illustration shows a car returning from a very successful hunt, loaded down with deer, jack rabbits, cotton tail rabbits, possums, badgers and coyotes.

The way they go after the game in Texas and how they get it

White ten-passenger bus carrying tourists over mountainous roads in Mount Rainier National Park, Wash.

Tourists traveling through Mount Rainier National Park embarking in motor buses at Longmire's Inn

Willman with Studebaker—G. L. Willman has taken an advertising position with the Studebaker Corporation, Detroit, Mich.

Leisaw Sales Manager—The Abbott Motor Car Company, Detroit, Mich., has appointed W. J. Leisaw as district sales manager for the states of Indiana, Michigan and Ohio.

Tire Salesrooms Opened—The new salesrooms of the Southern Tire Repair Company, Baltimore, Md., on Mount Royal avenue, near Maryland avenue, were opened recently.

Baltimore's Municipal Garage—An appropriation of $4,500 for the establishment of a municipal garage for Baltimore, Md., is included in the building inspector's account by the board of estimates.

Occupy New Salesrooms—The Baltimore, Md., branches of the Goodrich and Diamond tire companies, which consolidated recently, are now occupying the new salesrooms on Mount Royal avenue, near Maryland.

Boston Buys Buicks—The Boston, Mass., branch of the Buick Company sold last week to the fire department, wire department and the board of health three of the new model 30 roadsters for municipal work.

Cain, Chief Engineer—James W. Cain has been appointed chief engineer of the McCord Manufacturing Company, Detroit, Mich., with direct jurisdiction over the engineering, testing and experimental departments.

Columbus Has Eleven—The last of the motor-driven fire apparatus was received by the Columbus, O., Fire Department from the Seagrave Company recently and there are now four fire companies equipped with the apparatus.

Marion Gets Fire Auto—Marion, Mass., now has a motor combination chemical and hose wagon which was installed recently. It was presented to the town by Colonel Harry Converse, of Boston, Mass., a summer resident.

Beehler Company Odds—The Beehler & Ogden Motor Company, Baltimore, Md., has taken in the two-story building in the rear of its building at Lexington and Carrollton avenues to equip it for an up-to-date repair shop.

Powers Philadelphia Manager—F. W. Powers, manager of the Goodyear Tire & Rubber Company's branch, Washington, D. C., has been promoted to the managership of the Philadelphia, Pa., branch. His successor has not yet been appointed.

Greenburg Sales Representative—Alfred A. Greenburg, secretary of the Detroit, Mich., section of the Society of Automobile Engineers has undertaken the sales representation in that city of the products of the Baltimore Tube Company.

Murphy Succeeds Troutman—Ralph Murphy, formerly head of the inspection division of the H. H. Franklin Manufacturing Company, Syracuse, N. Y., has taken the managership of the service department, succeeding J. F. Troutman, resigned.

Martin, Traveling Representative—J. J. Martin has become a traveling representative of the Commerce Motor Truck Company, Detroit, Mich., which concern is working out a new line of machines to be brought out around the first of the year.

Detroit Firm Busy Again—The Detroit, Mich., Seamless Steel Tubes Company is again in position to accept orders for its products for shipment after January 1, it having been practically out of business since July 1, owing to a disastrous fire.

Metz Branching Out—Because of the demand for its cars in other sections the Metz Company, Waltham, Mass., has decided to open a branch in New York City that will be used as a station for distributing the cars to the middle Atlantic and western states.

More Oil Branches—E. A. Buck & Company, Worcester, Mass., one of the independent companies, has added two new stations to their chain in Massachusetts by opening branches at Greenfield and Medford, covering both the eastern and western parts of the Bay State.

Bus Service in Huntington—Motor bus service will be established in Huntington, Ind., by the newly organized Huntington Auto Transit Company. The city has ten thousand inhabitants, but has never had street car service, and there are no prospects of any in the near future.

Olean Wants Truck—The Adams Brothers Company,

Automobile Incorporations

AUTOMOBILES AND PARTS

Akron, O.—Motor Starting Company; capital, $25,000; to deal in automobiles and supplies and manufacture motors. Incorporators: R. A. Woods, M. Paul, E. W. Paul, A. M. Tschantz and C. L. Dinsmore.

Alton, Ill.—Alton Automobile Company; capital, $10,000; to repair automobiles. Incorporators: H. F. Horstman, William Winter, L. F. Winter.

Asbury Park, N. J.—Croce Automobile Company; capital, $250,000; to deal in automobiles. Incorporators: L. P. Croce, H. A Watson, T. G. Appleby.

Bedford, O.—Bedford Supply Company; capital, $10,000; to deal in automobiles and supplies. Incorporators: F. B. Senter, F. H. Calvert, G. W. Show, N. C. Boyd, A. B. Condon.

Brooklyn, N. Y.—American National Motor Bus Company; capital, $1,000,000; to purchase, lease and otherwise deal in motor buses, trucks, etc. Incorporators: C. A. Clarke, S. L. Conklin.

Cincinnati, O.—Northway Motor Company; capital, $600,000; to manufacture automobiles and engines. Incorporators: R. E. Northway, Wm. Pabodie, W. D. Friste, E. E. Decebach, F. B. Enslow.

Detroit, Mich.—Superior Motor Company; capital, $100,000; to manufacture a two-cycle motor. Incorporators: Henry Fraser, G. C. Brimmer and W. C. Schneider.

Indianapolis, Ind.—Huntington Automobile Transit Company; capital, $25,000; to engage in automobile service. Incorporators: J. M. Hicks, S. A. Stemen, J. W. Caswell, W. W. Hawley, O. E. Bradley.

Kansas City, Mo.—England Brothers Motor Car Company; capital $2,000; to manufacture automobiles. Incorporators: Edward England, E. W. England.

Mansfield, O.—Brucker Motor Car Company; capital, $5,000; to deal in automobiles and accessories. Incorporators: David D. Brucker, Wm. F. Voegle, Jr., Lewis Bruckert, Arthur E. Courtney and J. M. Ottinger.

Muskogee, Okla.—Pioneer Motor Company; capital, $5,000; to manufacture automobiles. Incorporator: G. S. Waddell.

New York City.—Rector Engine Corporation; capital, $150,000; to manufacture machinery. Incorporators: E. Gore, W. Magowan, S. C. Yeaton.

New York City.—Rolaff Oil Carburetor Company, Inc.; capital, $25,000; to manufacture and sell carburetors. Incorporators: R. Wolfsky, J. W. Stone, Wm. G. Van Vleck.

New York City.—The Kells Motor Radiator Corporation; capital, $650,000; to manufacture and deal in automobile radiators. Incorporator: H. R. Bingham.

New York City.—F. W. Ofeldt & Sons, Inc.; capital, $20,000; to deal in motor trucks, power wagons, etc. Incorporators: E. Y. Eltonhead, E. G. Ofeldt and Frank A. Ofeldt.

New York City.—Motor Trading Co., Inc.; capital, $10,000; automobile business. Incorporators: W. A. Shepard, Robt. W. Tindall and Albert Donces.

GARAGES AND ACCESSORIES

Chicago, Ill.—Illinois Tire Filler Company; capital, $10,000; to deal

Findlay, O., entertained one day recently a committee from the Olean, N. Y., fire department, headed by the fire chief, S. T. Rogers. The committee was looking over the Adams plant with a view of purchasing an automobile fire truck.

Kingsley's Racer Burned—The big 70-horsepower, six-cylinder Thomas car with which John J. Kingsley won the amateur championship of New England at races at Readville, Mass.; Rockingham Park, Salem, Mass., and elsewhere, was destroyed by fire recently at his summer home at Franklin, Mass.

Connell with Commerce—H. L. Connell, member of the recently established motor testing division of the Society of Automobile Engineers, Detroit, Mich., is engaged in engineering work for the Commerce Motor Car Company, of that city, which intends to bring out a line of motor trucks about the first of the year.

Nankivel, Foreign Distributor—Claude M. Nankivel, 17 State street, New York City, has been appointed foreign distributor for Stewart delivery trucks, manufactured by the Stewart Motor Corporation, Buffalo, N. Y. Mr. Nankivel will handle the sale of these trucks in Europe, Australia, New Zealand, South Africa and South America.

Reiman Sues Service Truck—Charles S. Reiman, of Chicago, Ill., has brought suit in the circuit court at Wabash, Ind., against forty-nine stockholders of the Service Motor Truck Company. He asks $50,000 damages because he was restrained from selling $20,000 worth of stock in the plant. The restraining order has since been dissolved.

Discharges 400 in Day—Every one of the 400 employees of the Catle Lamp Company, Battle Creek, Mich., makers of automobile lamps, from superintendent down to the boy, has been discharged from an order from the board of directors. On the following Monday the plant will re-open, hiring an entirely new force and affecting a thorough organization.

Physicians Win Their Case—The Boston physicians who protested to the Boston Street Commission against the ordinance that prevented them leaving their cars outside their residences or the places where they were on a professional visit have won their case, for recently the commission amended the ordinance excepting doctors from its provisions as well as clergymen.

League Conference—The Lowell, Mass., Automobile League had a conference recently with Commissioner Brown, of the Street Department, and City Engineer Kearner relative to the bad conditions of the streets and the Merrimac Valley boulevard. Specific instances were brought to the attention of the officials and they gave orders to have repairs made at once.

Baltimore Owners Fight Tax—Dealers and owners of automobiles in Baltimore, Md., are aroused over the municipal plan to introduce an ordinance for taxing cars from $5 to $50 in addition to the present three taxes now being paid by the owners—namely, $20 for owners' license, $2 for operator's license and a personal tax to the city and state. The Automobile Club of Maryland and all the dealers and owners will fight this unjust tax, if passed, by carrying the fight to the highest courts.

Indiana Clubs Joined—There is a movement on foot to organize all of the automobile clubs in Indiana into a state organization. A meeting will be held in the rooms of the Hoosier Motor Club in Indianapolis, Ind., on December 14, at which time a ways and means committee will be appointed to secure the formation of the state organization. An effort will be made to bring the clubs of Logansport, Indiana Harbor, Jeffersonville, South Bend, Fort Wayne, Kokomo, Salem, Muncie, Madison, Terre Haute and Winchester into the organization.

U. S. Rubber Adds—The United States Tire Company, operating four plants, is planning an expenditure of over $3,000,000 in factory improvements and extensions. First of all, the Morgan & Wright plant, which is located in Detroit, Mich., is to be doubled in both area and production. Six thousand workmen will be required when all improvements are finished. The output of the factory will be in excess of 5,000 tires daily. It is the intention of this company to also increase the facilities of the three remaining plants in Indianapolis, Ind., Hartford, Conn., and Providence, R. I.

In the heavily-wooded section of Mount Rainier National Park. Automobile buses conveying sight-seeing tourists

Party of tourists at the height of the season starting on a tour of Mount Rainier Park by motor bus

in vehicle wheels, tires, rims, etc. Incorporators: Albert Jacobs, Anton Percival, C. B. Stafford.

CINCINNATI, O.—The Citizens' Auto Service Company; capital, $7,000; to engage in automobile service. Incorporators: W. H. Davis, F. W. Kelly, L. J. Hoppe, A. Putman, J. L. Kohl.

CLEVELAND, O.—Dayton Airless Tire Sales Company; capital, $10,000; to deal in automobile tires and supplies. Incorporators: Wm. A. Carey, H. Krejoi, F. W. Chandler, R. M. Edwards and M. Otter.

CLEVELAND, O.—Dayton Airless Tire Sales Company; capital, $10,000; to deal in automobile tires, supplies, etc. Incorporators: W. A. Carey, B. Krejel, F. M. Chandler, R. W. Edward, M. Otter.

COLUMBUS, O.—Bracken Stauton Tire Company; capital, $5,000; to manufacture automobile tires. Incorporators: W. F. Bracken, M. B. Stauton, L. A. Stauton, May Bracken, T. E. Curtin.

GLEN COVE, N. Y.—Glen Cove Garage, Inc.; capital, $1,000. Incorporators: T. F. Meade, Edward Lewis and Lillian Lewis.

HAGERSTOWN, MD.—Hagerstown Automobile Club; to promote good fellowship, the use of automobiles, secure improvements to the roads and highways, assist in the enforcement of laws relating to motor vehicles and to secure legislation, and protect the interests of automobile owners. Incorporators: Albert Heard, S. H. Weihenmayer, Dr. Victor D. Miller, Jr., J. E. Stonebraker, Geo. A. Zook, E. W. Byrson, Wm. B. Littleton, Dr. J. McP. Scott, Dr. Royer Laughlin, Dr. W. Preston Miller, John A. Beck and Chas. M. Danzer.

INDIANAPOLIS, IND.—Ham-Meix Company; capital, $150,000; to manufacture acetylene self-starters and generators.

INDIANAPOLIS, IND.—Auto Lamp & Number Company; capital, $3,000; to manufacture a combination illuminated registration number and tail light. Incorporators: R. Griffin, A. P. Conklin, R. H. Bruce, W. F. Johnson and Geo. L. Maas.

LYNN, MASS.—Suffolk Street Garage; capital, $5,000; to repair automobiles. Incorporators: Daniel Lynch, John Buckley, Henry Thomas.

NEW YORK CITY.—Queensboro Garage, Inc.; capital, $10,000. Incorporators: F. A. Jockers, Augusta Jockers, D. J. Stack and Angelica M. Stack.

NEW YORK CITY.—Motor Dealers' Contest Association of New York, Inc.; capital, $30,000. Incorporators: Inglis M. Uppercu, Emanuel Lascaris and James C. Nichols.

NEW YORK CITY.—United Rubberine Supply Company, Inc.; capital, $200,000; to deal in tire fillings, rubberine, etc. Incorporators: Herman Maver, T. H. Royce, C. L. Bookheim.

PHILADELPHIA, PA.—Auto Safety Signal Lamp Company; capital, $100,000; to manufacture lamps and lighting devices of all kinds. Incorporators: L. Ables, Jesse Drew, J. G. Gray.

ROCHESTER, N. Y.—Rochester Macandaruba Tire Filler Company; capital, $10,000; to deal in tires, tire fillers, etc. Incorporators: Chas. S. Morris, John S. Crosier and Albert C. Olp.

CHANGES OF CAPITAL AND NAME

DETROIT, MICH.—Change of name from Republic Motors of Michigan to Republic Motor Car Co. of Michigan.

GALION, O.—Cleveland-Galion Motor Truck Company; capital increased from $300,000 to $1,000,000.

RICHMOND, VA.—Westcott Motor Car Company; capital increased $100,000.

Ward Leonard Electric Lighting System

Automatically Keeps Battery Charged and Lights Supplied—Has Only One Hand-Operated Switch—Ingenious Design of Magnetic Controller

EVER since it was realized that electric lighting for the automobile possessed innumerable advantages over all other methods of illumination, inventors have directed their efforts toward the design of an electrical system that would have the merits of extreme simplicity as well as certainty of action, so as not to require that the driver be a trained electrician in order to keep his lighting in working condition. The necessary components of such a system are a dynamo that will furnish current while the car is in motion and a battery arranged to receive its charge from the dynamo so as to provide current for the lamps when the car slows down or stops. It is further necessary for successful operation that the dynamo supply a constant current while charging and lighting, and it is here that the real difficulty of the problem lies. Owing to the varying speeds and stoppages which are associated with the automobile some kind of control is essential in the relation of the dynamo to the system; otherwise a varying current that would be dangerous would result. Numerous and various solutions have been offered, only a small proportion of which can be said to be satisfactory from all points of view. These can be divided roughly into two classes: first, those in which the required constancy of current is obtained by a mechanical control of the dynamo speed to render it independent of the speed of the car; and second, those in which the same result is attained by electrical control of the generating power of the dynamo, even though its speed varies with the car. In the former case, resort was generally made to the slipping clutch with centrifugal governor; while in the latter some method of field adjustment, either through brush position or rheostatic resistance was tried.

The Ward Leonard automatic dynamo lighting system is a successful system belonging to the second of the two classes mentioned. Its most notable feature is its extreme simplicity. It consists, so far as the owner need know, of a single switch fixed on the dash or under the driving seat, which is to be turned on when light is wanted and turned off when it is not wanted. All the operations of charging, connecting and disconnecting dynamo and battery are automatic. The switch is shown in Fig. 2, the central circular portion with the thumb lever in the left hand view being the only part visible on the dash.

Actually, the system, as supplied from the factory, comprises a shunt dynamo to be driven from the engine by silent chain or gear; an automatic electrical controller which switches on the dynamo when its speed is high enough to generate the necessary amount of current for charging and lighting, disconnecting at lower speeds; and the rotary snap lighting switch mentioned above, together with armored cable correctly wired up and provided with plugs ready for insertion into the lamp sockets.

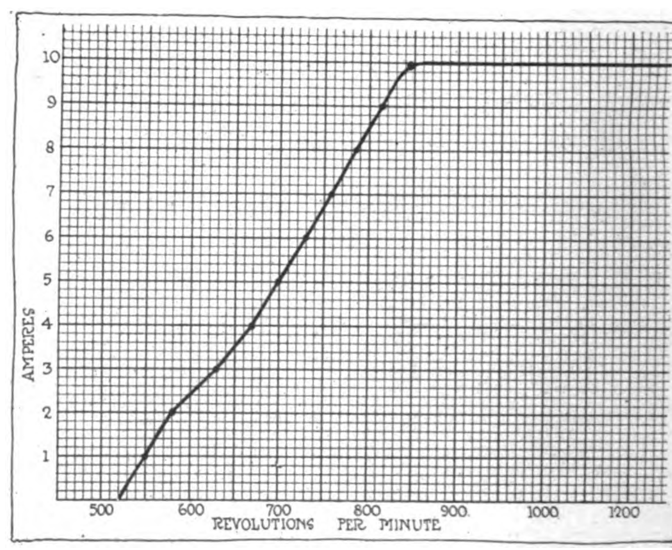

Fig. 3—Current output curve of dynamo in relation to speed

Fig. 1 shows the dynamo with the armature and brushholder removed. It will be seen that the magnet casing is of totally enclosed rectangular box form, allowing the maximum of power for a given space. It is a two-pole shunt wound machine weighing 24 pounds and supplying 10 amperes at 800 revolutions per minute. The armature is skew slotted and is run on Hess-Bright ball bearings of ample size. The commutator is large and is built up of many segments giving good wearing qualities with the least amount of sparking at the brushes. Carbon brushes, spring controlled, bear on each side of the commutator. They are fitted to a single brush holder, shown at the left of Fig. 1, which is fixed by four screws to the magnet casing. The current output of the machine, in relation to revolutions per minute is shown in the curve, Fig. 3, which has been plotted from actual tests. It will be seen that a current of 10 amperes is supplied when the speed reaches 800. At this speed the automatic controller is in action, preventing a larger output irrespective of any increase of the dynamo speed.

The automatic controller, shown with the cover removed in Fig. 4, consists of two magnetically operated switches and a small resistance unit, all three contained in a box 4 3-4 inches long. V is a coil of fine wire surrounding an iron core, which when sufficiently magnetized by the current flowing in the coil, attracts the iron arm V1 against the pull of the light spring V2 and closes the two contact points at V3. These are so wired as to permit the main current from the dynamo then to pass to the battery and lights. S is a coil of heavy wire wound on a similar core, which when magnetized with the main current allowed to flow by the action of the voltage switch as described above, attracts the arm S1 against the pull of the spring S2 and opens the contact points S3. This action puts the resistance coil R in circuit with the field magnet coils of the dynamo, weakening the latter to such an extent that the output in amperes is below that necessary to hold the arm S1, which is therefore released, cutting out the resistance again. It will be seen how this action repeats itself so long as the dynamo speed is kept up. In actual practice the switch arm S1 is vibrating at such a high rate as to have no effect whatever on the lights. In consequence of this rapid vibration the platinum contact S3 on the switch arm is not attached direct thereto but is fitted to a flat spring mounted on the arm. This construction is common electric practice, and its purpose is to give a slightly rubbing contact between the two platinum surfaces, thus keeping them perfectly clean. The switch arms swing on an extremely short phosphor bronze strip firmly riveted to the core casing. This does away with the danger of the wear which accompanies a pivoted hinge. In addition to the two coils V and S, a third auxiliary series coil is wound on the same core as V, the chief purpose of which is to insure the perfect demagnetizaton of the core should a reversal of current take place.

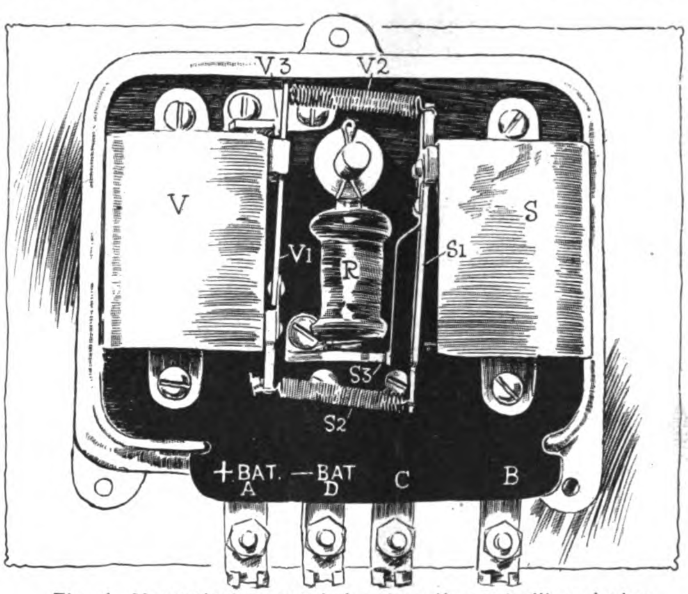

Fig. 4—Magnetically operated automatic controlling device

In Fig. 2 are given back and front views of the combined lighting switch and distribution panel. The latter is screwed to the back of the dash or inside the front seat panel and from it issue the brass-armored twin cables to the lamps, dynamo and battery. All inside connections are permanently soldered, so that there is no possibility of loosening through vibration. The switch itself is of the widely used rotary snap type, having four positions as follows: 1, side and rear lights; 2, headlamps and rear; 3, head, side and rear, and 4, off position.

Throughout the entire manufacture absolute interchangeability of all parts is secured by the use of well designed dies and drilling jigs and each set when complete undergoes a thorough test with lamps and battery arranged exactly as required on the car. All cables are cut to the proper length for the particular car to be fitted before leaving the factory, and provided with specially made plugs. The method of operation of the system as a whole can be seen by referring to the outline diagram of connections Fig. 5. Assume the dynamo to be turning, current will proceed to flow from the brush B1 along to the right as indicated by the heavy lines, through the coil of the series switch and thence to the arm of the voltage switch. At this point the main current suffers an interruption through the gap between the contacts V3. A small quantity of current, however, can pass through the shunted coil of the voltage switch, shown in fine lines, and return by the lower heavy lead to the dynamo brush B2; and when the speed of the car, and consequently of the dynamo, increases so as to bring up the voltage to a certain pre-determined amount necessary for charging the battery, the current so flowing is sufficient to pull over the switch arm of the voltage switch, thus connecting the main current to the battery and lighting circuit. The dynamo can now supply its full output of 10 amperes, running at 800 revolutions per minute, which corresponds to a car speed of roughly 14 miles per hour. Assume, now, that the speed of the car is increased so that there is a tendency on the part of the dynamo to generate more than the necessary 10 amperes. The increased amount passing around the coil of the series switch attracts the arm, opening the contacts S3 and thereby making it necessary for the shunted current of the dynamo field coil, shown at the left, to pass first through the resistance unit, which previously had been short-circuited. This weakens the field and consequently the output of the dynamo, and the switch arm flies back. As described above, there follows a constant vibration of the switch arm, alternately inserting and cutting out the resistance unit at an extremely rapid rate, resulting in an absolutely constant supply of current.

When the car is standing still or running slower than 7 miles per hour the dynamo is entirely disconnected from the battery by the gap V3 and the battery is automatically connected.

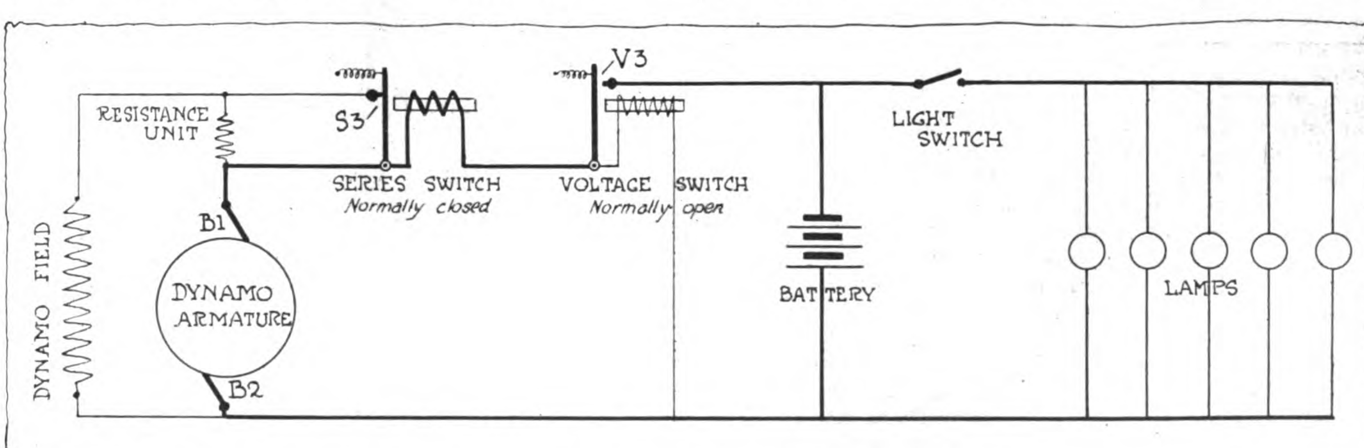

Fig. 5—Outline wiring diagram of the Ward Leonard lighting system for automobiles

Roberts Sectional Cell Tube; Comfortable Automobile Spectacles; New Spring Bumper; Nickel-Plating Compound; Winter Side Curtains; Standard Vulcanizing Bag; Splitdorf Coil-Switch

Roberts Sectional Pneumatic Tire

AN IDEA original in its specific field, although tried with success in other departments of engineering, is used in the Roberts sectional tube, Figs. 1 and 2. This tire is designed to take the place of the pneumatic inner tube and is practically punctureproof, inasmuch as, even if the rubber is punctured in any one place, the tire does not give out as in case of a conventional inner tube. The Roberts substitute for the tube consists of ten sections which when placed in the tire casing fill it completely, exactly like an inner tube. Each tube in turn is formed of thirty hexagonal cells, each of which is individually closed at both ends. The air in each cell is under the pressure corresponding to the size of the casing in which the tube is used. In the making of the tube each section, with the cells closed at one end, is placed in a special machine, where the cells are filled with the proper amount of air to obtain the right pressure, being vulcanized after the sufficient quantity of air has been introduced in every cell. As each casing is thus filled with 300 independent inner tubes in each of which the proper inflation pressure exists, it stands to reason that even if, say, seven cells of a section are punctured, the remaining twenty-three will keep it in good working shape. If a section has so suffered that it gives no more good service it may be replaced by a new section. It is intended by the Roberts Rubber Manufacturing Company, New York City, to guarantee the tube for a great number of miles and to soon take up its manufacture in large quantities.

Willson's Albex Folding Goggles

T. A. Willson & Company, Reading, Pa., are the manufacturers of the goggles, Fig. 2, which are made of soft material excepting the lenses. The sides of the goggles are made of soft leather and formed with a number of holes each, so as to permit of some ventilation for the eyes and to prevent sweating of the lenses. The latter are held in silver-plated rings and are furnished in amber, smoke tint, white and Fieuzal, according to the wish of the purchaser. A soft strip of material forms the bridge which rests on the nose and flexible cable temples permit of holding the goggles in place with great ease. The appearance of these goggles is very distinguished and decidedly sportsmanlike. The goggles are furnished in a handy leather case finished in seal grain, which is small enough to go into a pocket and which in itself adds materially to the appearance of the outfit.

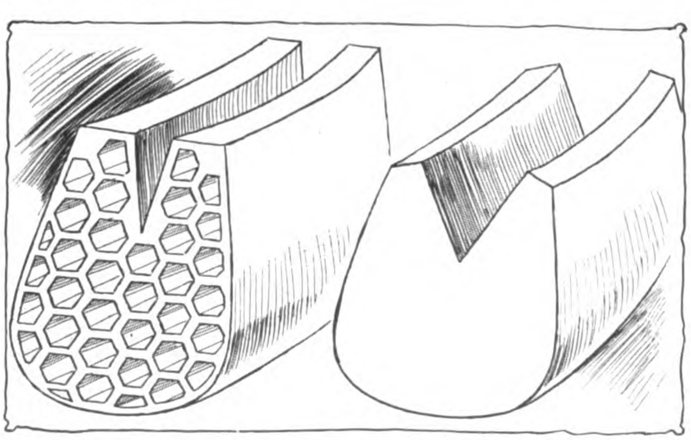

Fig. 1—Roberts sectional, cellular inner tube

New Randerson Steel Bumper

The new bumper of the Randerson Auto Parts Company, 110 West Thirty-fourth street, New York City, is distinguished by being made of steel throughout. The construction features, which have not been altered, are seen in Fig. 6, while the appearance of the double type of bumper is shown in Fig. 7. The principal new point is the use of steel for the connecting arms C, in which the bumper bar is supported and which are secured to the side members of the chassis. These bars are fashioned with a clamp at one end, into which fits the bumper bar, while the other end fits into a cylinder containing the shock-absorbing elements of the bumper. These consist of a piston P slidable in the cylinder C1 and a large spring S which is compressed between the piston P and the end E of the cylinder, when the bumper car strikes an object. The small spring S1 coiled inside of S serves another purpose; one of its ends is secured to E and the other to the head Q of the piston P, tending to pull the latter as far as possible toward E. The joint J connects the head Q and the connecting bar C, permitting of a swivel motion of the latter when it is pulled out of the end E1 of the cylinder C1. By this expedient the bar connection C may be turned up or down, to clear the starting crank. Fig. 7 shows another type of bumper in which two bars are used. The Randerson company makes a variety of types, some of which include the up-and-down feature and which differ principally by the kinds of bumper bars used. Round and square tubes as well as I-beam forgings may be obtained for the bars.

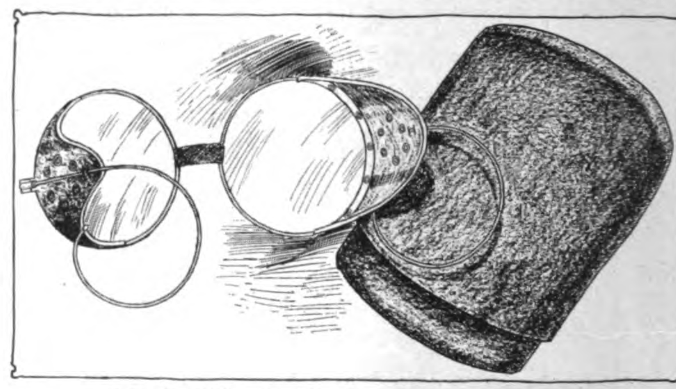

Fig. 2—Willson's Albex comfortable spectacles

Zeuss Royal Nickel-Plating Salt

R. F. Lang, 31 Broadway, New York City, is the importer of a nickel-plating salt specially adapted for plating metal ware used on automobiles, which is exposed to the inclemency of the weather. The salt furnished for this purpose is emerald green and crystalline in structure. To prepare the electroplating bath, 1 part by weight is dissolved in about 4 parts of water, the best proportion being 25 gallons of water to 55 pounds of the plating salt. The dissolving should be done in lukewarm water and the bath be slightly acid; which means that it should redden blue litmus paper slightly. If the litmus is reddened intensely the bath contains too much acid and should be weakened by adding caustic soda until the paper shows a faint red. A current from .6 to 1 ampere at 2.5 or 3.5 volts should be used for electroplating, the exact voltage depending on the number of pieces treated simultaneously in the bath and on the distance of cathode and anode. The exact voltage is, therefore, a matter which only experiment can teach. The temperature of the bath should not fall below 65 degrees Fahrenheit.

Studebaker 20 Side Curtains

The Studebaker Corporation, Detroit, Mich., has just developed a new side-curtain scheme for its Twenties, a type of car favored by doctors, etc. These side curtains are so constructed and mounted that they swing with the doors, their front edge being attached to the windshield frame, while the lower edges are secured to the door. A flap arranged to fall in line with the top edge makes a tight close there, while the back edge is fastened to the top by means of spring clips. In this way the curtains become units with their doors and may be opened and closed from inside the car, thereby saving the owner a great deal of uneasiness, which is ordinarily encountered in attaching the side curtains in Winter. By this arrangement the Studebaker 20 is transformed into a real Winter automobile, giving the passenger all the comfort of a larger car.

Splitdorf Coil Switch TS

The Splitdorf Electrical Company, New York City, has brought out a new type of coil switch which serves for both controlling and stepping up the ignition current generated in the Splitdorf low-tension magneto. As the schematic view, Fig. 4, shows, the coil switch is designed to be fitted to the dashboard, with the nickel-plated face protruding through the same and being in reach of the driver. The instrument consists, as its name implies, of a step-up coil and condenser working in combination with a switch. The latter is composed of two pieces of metal insulated from one another, which make contact between the several terminals to which the current flows after entering the device. The battery current enters through B1 and B2, flowing thence to B3 and B4, respectively. The magneto current flows through the contacts N, N1, M1, C3 and D. The contacts C3 and M1 are fitted with extension contacts, as shown by dotted lines in Fig. 4. The operation of the coil, with battery and magneto current used, is as follows:

When the switch is the magneto position, the two connector pieces on the switch face connect N1 with M1 and the extension of M1 with C3. The current produced in the magneto enters at N, passes to N1, M1 and C3, whence it flows—to the right in Fig. 4—through the primary winding of the coil shows as a heavy zigzag line and to D which is grounded. As the current passes through the primary winding, it induces a high-tension impulse in the secondary winding, which latter is connected to the grounded contact D and to G which is wired to the timer. When the battery system is used for ignition, the current enters through B1 and from B3 flows to the extension contact of M1, while B2 leads to B4 and through the switch contact to the extension of C3. From M1 it passes through the condenser C1 into the primary winding and thence back to C3, closing a complete primary circuit. The secondary circuit is excited in the same manner as in the case of the magneto current being used.

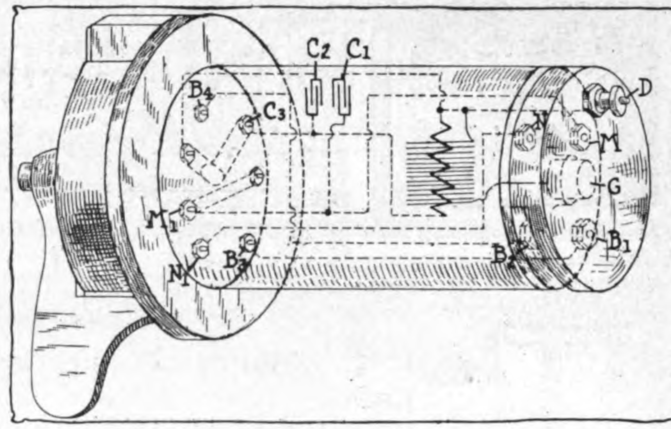

Fig. 4—Schematic view of TS Splitdorf coil switch

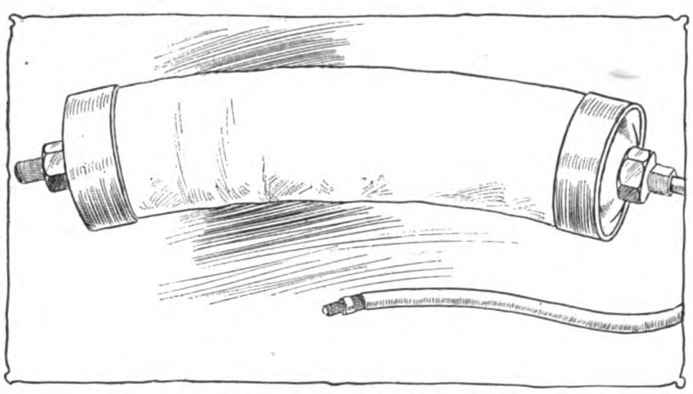

Fig. 3—Standard air bag for casing vulcanization

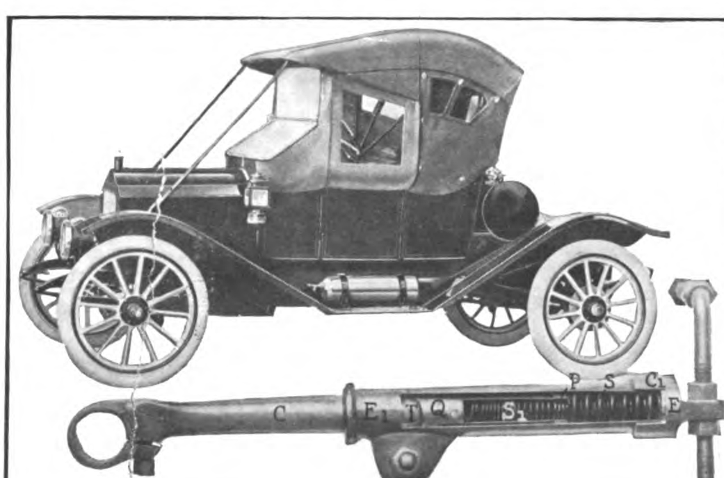
Thermite Anti-Freezing Solution

The Northwestern Chemical Company, Marietta, O., has begun to manufacture a compound which is added to the radiator water to prevent its freezing. This solution is called Thermite and in its pure state freezes at about 70 degrees below zero, while if mixed with an equal volume of water freezes at about 15 degrees, and if mixed with half its quantity of water, at 40 degrees below zero. The price of the compound is very reasonable, so that even a rich mixture of it may be used.

Standard Vulcanizing Air Bag

Operators of vulcanizing plants will find the Standard air bag, Fig. 3, a very useful accessory in their businesses. This bag is made of a canvas cylinder closed at each end by a metal head tapped for a screw-threaded plug. A plain plug is fitted into the hole of one plate, while the other one is equipped with a coupling to the end of which a piece of fabric-wound rubber hose is attached. This hose is fitted with a regular inflation valve, which permits of forcing compressed air into the bag, either by means of a tire pump or from an air compressor. The canvas is wound many times to form a wall practically impenetrable for the compressed air, and it is held tight against the end plates by two welded rings. The use of this bag is identical with that of any other vulcanizing bag; it is placed in the section of a tire casing which is to undergo heat treatment in the vulcanizing mold, so as to press the casing tightly against the mold. This bag is made by the Standard Tire & Rubber Company, Boston, Mass.



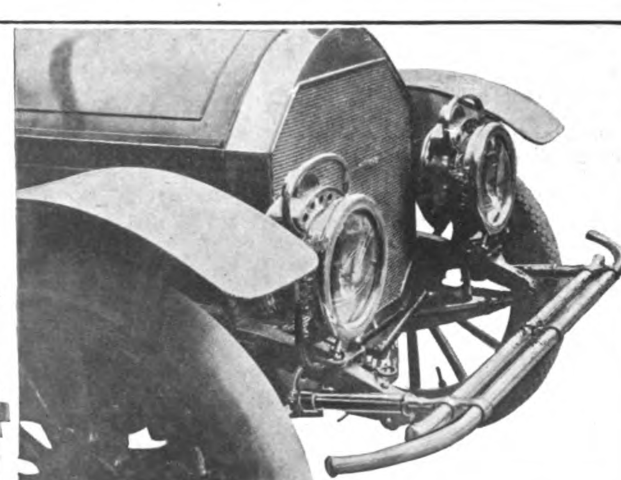


Fig. 5—Studebaker close winter side curtains. Fig. 6—Interior view of Randerson bumper mechanism. Fig. 7—Randerson double-rail bumper on car

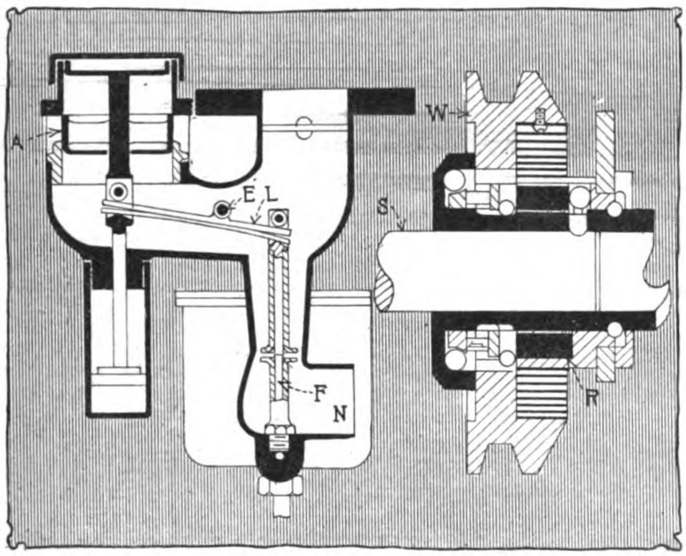

Fig. 1—Schulz positive carbureter. Fig. 2—Sharpe starter

CARBURETER Construction—In which air and fuel admission are both regulated by valves actuated by common lever means.

The subject matter of this patent, a carbureter, is shown in Fig. 1. It is of the float-feed type and fitted with a nozzle of variable orifice. The latter is regulated by means of the fuel valve F, the upper end of which is pinned to the lever L which is fulcrumed at E. The other end of the lever L is connected to the air inlet valve A which is of the sleeve type and serves as auxiliary supply, while the normal supply at low speeds enters through N, blowing past the fuel nozzle, where it vaporizes the gasoline. In connection with this construction, means are provided for moving the lever in two directions and holding it in any adjusted position.

No. 1,046,111—to Carl F. Schulz, Brooklyn, N. Y. Granted December 3, 1912; filed August 21, 1911.

Engine Safety Starting Device—Comprising a constructional detail for engaging the crankshaft when starting and for disengaging it after the engine has begun to work.

This patent has reference to a ratchet construction useful in engine-starter constructions, the subject matter being illustrated in Fig. 2. The crankshaft is seen at S and a wheel W is mounted on it, but not keyed to it. Between the shaft and the wheel a ring R is interposed which serves as a bearing for the wheel. Both the wheel and the shaft are formed with ratchet recesses in which balls are located, and the ring has openings registering at their opposite extremities with these recesses; the effect thereof being that when the wheel is turned in one direction it actuates the shaft, or if the shaft is turned in the opposite direction it actuates the wheel. Means are provided by which the ring is shifted longitudinally along the shaft, if the crankshaft rotates contrary to its operating direction, whereby the balls are disengaged from the ratchet recesses of the engine shaft, permitting the latter to move without producing a reversed torque in the starter mechanism.

No. 1,046,030—to William A. Sharpe, Denver, Col. Granted December 3, 1912; filed October 16, 1911.

Valve Spring Compressor—In which the members used for compressing the spring are adjustably connected.

Fig. 3 shows the device described in this patent consists of two spreader members, one of which M is pivoted to the end of a screw-shaped connector piece S and the other M1 is mounted on S, so that it may be worked along its thread by actuating a thumb-nut N. The opposite ends of M and M1 are shaped with forks which engage the valve springs; the forked end of M being larger than that of M1 and being formed with inwardly projecting lugs. A bail is pivoted at the end of M and adapted to be fastened over the end of M1.

No. 1,045,321—to Philip F. Pillines, Philadelphia, Pa. Granted November 26, 1912; filed July 20, 1912.

Tire Inflation Valve—Which is fitted with a closing device at its inner end to prevent leakage.

The tire valve described in this patent is shown in Fig. 4. This valve has a tubular portion T which extends within the tire tube and is positioned inside of an outer Tube T1 clamped upon the tire. A packing is in place between the two telescoping members T and T1. A valve through which the tire is inflated is contained in T; T is movable outwardly in T1 by air pressure inside of the tire. A head H formed on T1 forms a seat for the closing device C which is subject to the pressure obtaining in the pneumatic tube inside the tire, thereby keeping the inflation valve closed tightly.

No. 1,045,330—to Maximilian Charles Schweinert, West Hoboken, N. J. Granted November 26, 1912; filed February 10, 1909.

Automatic Lamp-Controlling Device—Consisting in a connection between the tie-rod and the lamp supports.

This patent refers to a lamp-controlling device in which the lamps are mounted on U-shaped forks, the single ends of which are fitted with one laterally extending arm each. These lateral extensions are made to engage the tie rod of the steering gear in such a manner that, if the tie rod is moved. the lamps are brought to turn in the same direction as the front wheels.

No. 1,046,010—to Oliver W. Page, Ione, Wash. Granted December 3, 1912; filed September 28, 1911.

Automobile Muffler—Being of the baffle plate type.

The muffler referred to in this patent comprises a casing, a series of inner baffles aligned along the axle of the casing and a series of outer baffles attached to the wall of the casing and spaced somewhat from the inner ones. Thus an unobstructed substantially straight passage is provided for the exhaust gases, as the baffles are mounted in staggered relation.

No. 1,045,936—to Eugene Bivert, Chicago, Ill. Granted December 3, 1912; filed January 22, 1912.

Pneumatic Tire Patch—A shield and guard flap protecting a repaired portion of an inner tube.

This patent has reference to a repair patch comprising a flexible strap encircling the tube, which is adjustable in length by means of members attached to its ends. Inside the strap is a member which spans the punctured portion of the tube; the ends of this member extend beyond the corresponding end of the strap.

No. 1,045,955—to Mark A. Dees, Pascagoula, Miss., assignor to American Tire Company, St. Louis, Mo. Granted December 3, 1912; filed January 3, 1911.

View of the Paris Salon, looking across the main exhibition space in the Grand Palais

Within the Walls of Paris

Paris Salon Opens with 565 Exhibit Stands—Twenty American. Is of a More International Character Than Olympia Show. Floor Space of 260,000 Square Feet Proves Inadequate.

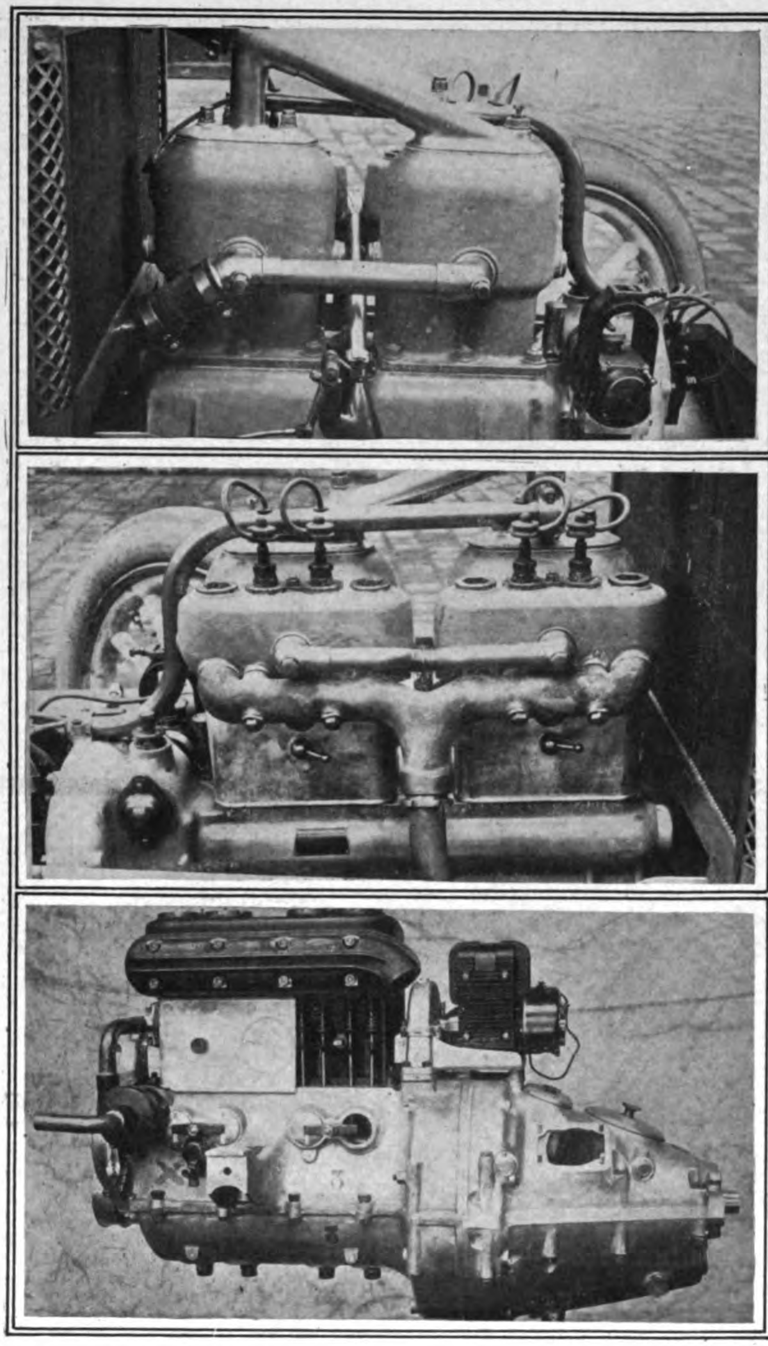
PARIS, Dec. 7—The Paris Salon, which opened this evening in the Grand Palais, attended by President Fallieres and half a dozen of his ministers, together with local dignitaries, is the largest exhibition of motor vehicles ever assembled under a single group. There are 565 exhibit stands, and the total floor area is 260,000 square feet. Although the largest numerically, the Salon which opened here today is less international than the Olympia show at London a few weeks ago. In the present Salon, which is the thirteenth to be held in this city, the majority of the exhibitors are French, there being relatively few foreign makers, and the number of these exhibitors being often largely made up of accessory people. Here are some of the figures:

America	20 exhibitors
Great Britain	34 exhibitors
Belgium	9 exhibitors
Germany	12 exhibitors
Italy	9 exhibitors
Switzerland	6 exhibitors

Although Great Britain shows thirty-four exhibitors, only eight of these are exhibiting cars, the remaining twenty-six showing accessories. Of the twenty American firms exhibiting, the following show cars: Abbott, Anderson Electric, Buick, Cadillac, Case, Century, Ford, Flanders, Hupmobile, Mitchell, Oakland, Overland, R. C. H., Reo and Studebaker. Some of the accessory exhibits are: Bowser, Goodrich, Klaxon, Vacuum, Potter & Johnston, T. Pilter and Oildag.

Germany shows twelve makes of cars; Italy and Belgium each have nine, and Switzerland is represented by six car and body manufacturers. Altogether there are ninety foreign and 565 home firms in the Grand Palais, this being a higher proportion of foreigners than on any previous occasion. In making this count only firms having a separate stand have been considered. There are a number of foreign manufacturers in the accessory business whose goods are handled by French houses; these have been counted in with the French firms.

Big as it is—for there is doubtless no other hall in Europe offering a floor space of 260,000 square feet, the Grand Palais has proved too small for its needs. As far back as July every inch of space had been rented. The 200 firms having been crowded out appealed to the organizing committee to open an



Two New French Motors

Top—Renault 11-horsepower motor, 75 x 120 mm.
Center—Renault 11-horsepower motor, valve side.

Bottom—Exhaust side of new Panhard 10-horsepower motor designed with gearset as a unit construction. The method of inclosing the valve tappets is shown. Gearbox inspection plates are numerous

overflow section, but this request was not acceded to. Consequently an independent organization undertook to get together an overflow section and for this purpose secured the Jardin de Paris, one of the amusement centers in the Champs Élysées, usually only open during the summer months. This section will open December 14, and will keep open until the new year. On the opposite side of the river, within a stone's throw of the Grand Palais, there is a third exhibition, devoted entirely to second-hand cars and accessories. Doubtless by facilitating the sale of used cars an impetus will be given to business in the main hall.

As stated in the special cablegram to THE AUTOMOBILE, tonight (this cable appeared in last week's issue, page 1209) France has gone unmistakably on record in favor of the long-stroke motor. She is also in favor of the small motor. The following figures show how the country stands in this respect, these figures, of course, including those cars on exhibition,

New De Dion 1913 Model

Upper—The De Dion-Bouton 12-horsepower model, valve side
Lower—Front De Dion motor, showing chain drive for camshaft

the tabulation showing the numbers of motors exhibited with different bore expressed in millimeters and also in inches:

No. of Motors	Bore, mm.	Bore, Inches
7	60	2.36
40	65	2.55
31	70	2.75
62	75	2.95
72	80	3.14
18	85	3.84
50	90	3.54
7	95	3.74
38	100	3.93
37	110-140	4.33-5.51

Further analysis shows that of all the motors exhibited there are thirty-three models with a stroke-bore ratio of 2 to 1, that is, the stroke is double of the bore. These 2-to-1 motors are not confined to newer companies building for sensational purposes, but conservative leaders like Panhard have brought out new types of this dimension.

While the 2-to-1 motor has a big showing, 50 per cent. of the entire French motors for next year have a stroke-bore ratio of 1.5 to 1. A very careful analysis of the situation shows that there is not a square type of French poppet-valve motor on the market. By square motor being meant one in which the bore equals the stroke.

The four-cylinder motor is the great leader; the six comes second, the single-cylinder third, and the two-cylinder last. The figures are:

Four cylinder motors	321
Six cylinder motors	20
One cylinder motors	15
Two cylinder motors	11
Eight cylinder motors	2

Up to the present De Dion-Bouton is the only company marketing eight-cylinder makes, and in this respect it is specializing on a smaller model for next year.

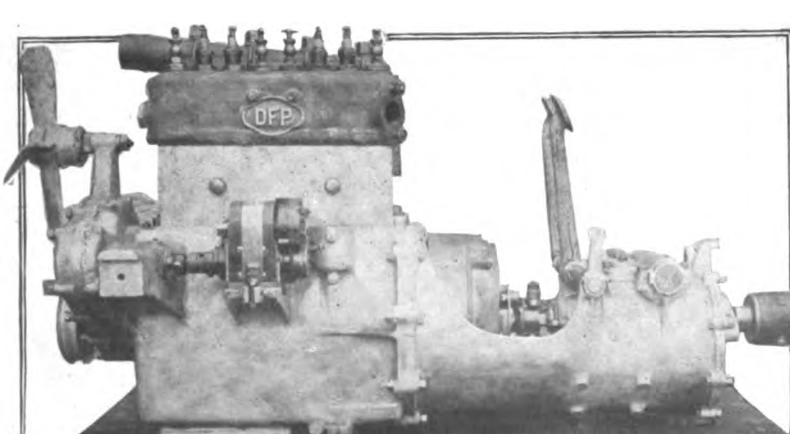
The non-poppet motor is not shown in the profusion it was a year ago. There are six different types, of which the Knight sleeve-valve type is the popular leader. It has gained several adherents during the year, who, while they could not procure manufacturers' licenses are purchasing the motors from companies that have such licenses. In this class are such concerns as Mors, Clement-Bayard, Gregoire, Aires, N. A. C., Kraft, Martini, Sigma, and, of course, Panhard, Mercedes, Rossell, Minerva, Daimler, Austrian Daimler, etc. Some of the other non-poppet concerns are: Darracq, Rolland-Pilain, Itala, Schneider, Piccard-Pictet, C. I. D., C. L. C., and in addition to these regular listed ones, Peugeot and Delahaye have announced that they may bring out some before the middle of next year.

Practically No Startling Designs

Like its London predecessor, the show is one of only moderate changes and practically no startling designs. Statistics would show that the average horsepower has not shown any increase, but this is the fault of the statistics. The official European formula for calculating horsepower practically ignores stroke, and as piston strokes have been steadily increased, and horsepower has gone up a little with the larger cylinder capacity. This, of course, is not brought out in the statistics; as examples of the errors into which the uninitiated may be led by the method of calculating horsepower, may be mentioned the Sizaire & Naudin 70 by 170 millimeters which is officially of lower horsepower than the same firm's 75 by 120-millimeter model; also the Hispano-Suiza's 80 by 180 millimeters, which has the same rating as the firm's 80 by 110 millimeters.

The average horsepower stands at 16, European rating, which is slightly in excess of that of 2 years ago.

The average cylinder bore, considering four-cylinder models only, is about 80 millimeters, 3.1 inches. Only a very small number of cars are being made with more than 4-inch cylinder bore, while a very big proportion of the French models are built with motors of 70 and 75 millimeters, 2.7 and 2.9 inches. About 50 per cent. of the French makers limit the size of their motors to 80 millimeters, while, where larger types are



Unit power plant of D. F. P., a new French motor

built, they generally comprise a small proportion of the firm's total output. Delaunay-Belleville, Hotchkiss, Mercedes, Metallurgique, Lancia, Itala, Unic, Leon Bollee and Minerva are at present the leading firms which produce a majority of their cars with motors of more than 3.1 inches bore.

The longest stroke on the practically commercial models is 180 millimeters, 7.08 inches, on one of the Hispano-Suiza cars, the cylinder bore of which is 3.1 inches. Pipe has also 180-millimeter stroke for a bore of 100 millimeters. Sizaire & Naudin is second with 170 millimeters, 6.69 inches, stroke for a bore of 2.7 inches. Other long strokes are Gregoire with 80 by 160, La Buire 80 by 160, Chenard & Walcker 80 by 150, Renault 100 by 160, Brasier 100 by 150, and, significant, Panhard with 70 by 140.

There is no case in which the stroke has been reduced, but a considerable number in which it has been increased a little. Delage, for instance, has changed his four-cylinder from 75 by 120 to 75 by 130 millimeters, and his six-cylinder from 66 by 120 to 65 by 130; Piccard-Pictet has changed from 90 by 130 to 90 by 150 and 90 by 170; Bozier and Alcyon have each changed from 75 by 120 to 75 by 130. Finally, Ballot, one of the largest motor makers for the trade, has added 10 millimeters to the stroke of nearly all his motors.

For motors of 65, 70 and 75-millimeter bore it is the common practice to fit two-bearing crankshafts, the crankchamber having no horizontal division. This method is adopted by Unic, Ballot, Chapuis & Dornier, Sizaire & Naudin, Delahaye, Chenard & Walcker, De Dion-Bouton, D. F. P. and Pilain. Delage, after using two-bearings for his 75-millimeter motor has adopted three for the coming season, and all the firms mentioned above adopt three main bearings whenever their motors exceed 75-millimeter bore. Panhard, it may be mentioned, has decided on three bearing for the new 70 by 140-millimeter type just put on the market.

The disadvantages of two-bearing crankshafts outweigh the advantages when the size of the cylinders gets beyond 75 millimeters, and among the firms mentioned there are some who have had to redesign their motors with a stiffer shaft and longer bearings to get rid of the suspicion of whip when running heavily loaded.

Six-Cylinders Not Increasing

Six-cylinder motors are not on the increase. Delaunay-Belleville makes a specialty of this type of motor and is one of the few firms building more sixes than fours. There are about half-a-dozen firms having abandoned some or all of their six-cylinder models, among these being some factories never having built more than a very small number of sixes, and there are about three firms bringing out a six for the first time. Improvements in the flexibility of the four and the increasing cost of fuel are important factors against the further extension of the six-cylinder motor.

Although far from being in the majority, there is a pronounced tendency towards the adoption of unit construction for motor and gearbox. Panhard took this up a year ago and has extended it to all the models; D. F. P. has adopted it for the coming season; Gregoire has one model with the clutch and gearbox united; F. L. has a power plant of this type; Hispano-Suiza and Piccard-Pictet have adopted this construction from the beginning; Motobloc, generally admitted to be the originator of this

Janney Joins R. C. H. As General Manager

Succeeds J. F. Hartz, Who Resigns on Account of Other Business—Hartz Retains the Treasurership

Conference of Branch Managers Taking Steps to Replace a Number of Branch Houses by Dealers

DETROIT, MICH., Dec. 17—*Special Telegram*—P. R. Janney, at present general manager of the Peninsular Motor Company, Saginaw, Mich., maker of the Marquette car, will on January 1 become general manager of the R. C. H. Corporation to succeed J. F. Hartz, who was chosen to direct the concern's affairs on November 8, following the reorganization of the company. Mr. Hartz's resignation is ascribed to his inability to devote sufficient time to the R. C. H. affairs owing to his other business interests. Mr. Janney has been associated with the General Motors for some time prior to taking hold of the Marquette affairs, he having been engaged to look after the Randolph Motor Car Company's business. Mr. Hartz retains the office of treasurer.

A hurried conference of R. C. H. branch managers from all parts of the country was held in this city today, the new management being made known to them. One of the objects of this conference was to take steps for the discontinuance of a number of branch houses and to replace them by dealers. This move should greatly decrease the corporation's operating expense.

Huber Suit Fought by Kelly Company

DETROIT, MICH., Dec. 17—Hearings were begun in Detroit this week in the alleged patent infringement case of the North American Vehicle Company against the Detroit Taxicab and Transfer Company. The hearings are being conducted before E. P. Voorheis, clerk of the United States court, special examiner for the case, and are being held in the office of R. A. Parker, of the law firm of Parker & Burton, counsel for the plaintiffs.

The vehicle company alleges infringement of the Emil Huber patent relating to three-point suspension of the main frame of an automobile. The Kelly Motor Truck Company, of Springfield, O., whose cars the Detroit company is using, is defending the case for the Detroit concern through its attorneys.

$1,000,000 Company to Make Vaughan

The Vaughan Motor Car Company, capital $1,000,000, has just been incorporated to take over the Woods Manufacturing Company, of Kingston, N. Y., and to continue making the Vaughan car. It is tentatively proposed to make 500 automobiles in 1913.

The new company will have $300,000 of cumulative preferred stock and $700,000 of common. Aside from the bare announcement of incorporation, no details as to the personnel of the new company and its manufacturing program were made public.

Grabowsky Property on the Block

DETROIT, MICH., Dec. 14—Lee E. Joslyn, referee in bankruptcy, has given notice to creditors of the Grabowsky Power Wagon Company, of Detroit, bankrupt, that property of the company will be sold by the Security Trust Company, Detroit, trustee, which will receive sealed bids in its office in Detroit up to December 23. Each bidder is required to deposit a certified check, payable to the trust company, to the amount of 15 per cent. of its bid, and each bidder may bid upon the whole or any separate parcel of the property, the deposit to be forfeited should the bidder, after being declared successful, refuse to carry out the provisions of the bids.

The inventory includes real estate to the amount of $168,552.98, which is appraised at $140,000. Other items are: Machinery, inventory $60,777.84; appraisal, $42,456.68; equipment, $10,255.10; appraisal, $6,026.26; furniture and fixtures, inventory, $6,809.73; appraisal, $5,144.42; jigs and tools, inventory, $19,517.04; appraisal, $16,032.19; patterns, inventory, $11,913.41; appraisal, $5,848.31; material, inventory, $122,023.30; appraisal, $100,696.88; miscellaneous, inventory, $448.01; appraisal, $436.60. The inventory total is $400,297.41, while the total of the appraisal is $316,641.34.

Of the amount bid 15 per cent. must be paid by December 25 and the balance as soon as the property is turned over. The Grabowsky Power Wagon Company was adjudicated a bankrupt by Judge Tuttle in the United States District court in Detroit, November 23.

Briscoe Men To Make Radiator

DETROIT, MICH., Dec. 16—With a capital of $30,000, which soon will be increased to $125,000, former employees of the Briscoe Manufacturing Company and others have organized the Farlinger Manufacturing Company for the purpose of placing on the market a new automobile radiator, the invention of George E. Farlinger, of Detroit, for many years superintendent for the Briscoe company, and after whom the new company is named.

The plant of the Waterman Marine Company has been leased and the manufacture of the new radiator will be begun within a month, by which time the marine motor company will be occupying its new plant now in process of construction on the east

Automobile Securities Quotations

Few automobile stocks made any gain during the past week: quite a number were steady and the majority fell back. Trading was not heavy and there was no evidence of bear aggression. The sales were mostly for the long account as realizing, liquidating and profit taking business had been finished at higher figures. Miller, which was one of the three issues to show a sharp advance last week, continued its upward course, making a net gain of 2 points but Firestone and Swinehart fell back. The tire stocks generally were weak. Nothing discouraging of an industrial nature transpired. The table follows:

	1911		1912

side. Special machinery has been ordered and at present the work of getting out the dies is being conducted. The Farlinger company will have a building 75 by 100, one story in height, but will have a lot large enough to accommodate an addition to the plant, which, it is expected, will have to be built within a short time.

The officers of the new company are: President, George E. Farlinger; vice-president, Otto J. Groehn; secretary, William H. Arthur, Marshall, Mich.; treasurer, Charles R. Talbot; general manager and chairman of the board, Frederick C. Arthur; directors, the officers and Maurice Friedburg and Alex. J. Ranstadtler.

All the officers are Detroit men with the exception of William H. Arthur, and all, with the exception of William H. Arthur, Charles R. Talbot and Maurice Friedburg, formerly were employed by the Briscoe company.

The new radiator is of the honeycomb type, and, instead of having from 500 to 5,000 pieces, as is the case with most radiators of standard size, has only 25 pieces of metal. The radiator proper is a series of hollow plates which may be standardized and made interchangeable.

Crude Rubber Easier All Around

After touching a level of $1.11 a pound for up-river fine, the crude rubber market sagged off to $1.09 1-2 in response to slackening demand as compared with conditions last week. The fortnightly auction in London begins Tuesday and a preliminary survey of the situation shows about 800 tons to be marketed. Importations over Sunday amounted to about 5,000 packages, of which nearly half was guayule from Tampico. Sales in the open market are less in volume than they were last week when the market was stiffer, but the majority of transactions were consummated privately.

Market Changes of the Week

Considerable activity reigned in the various markets this week, and the usual fluctuations in prices occured. A stronger tone was developed in the New York City market for tin yesterday, following a sharp advance abroad. Tin closed at $5.00 per 100 pounds at an increase of $.07. Lead remained dull and easy, closing at a loss of $.02 1-2. Electrolytic copper remained dull and nominally unchanged. Consumers continue out of the market, or are only buying small lots from second hands at prices from $.00 1-4 to $.00 1-10 under the asking prices of the combined producing interests. There were no developments in the local market for scrap rubber. Dealers report a moderate demand from reclaimers.

Kilbourne Cancels Dayton's License

Step Was Taken in Accordance with Clause Permitting the Cancellation of Concern if Involved in Litigation

Hereafter Company Must Buy Its Motors from a Licensed Manufacturer—Same Applies to Columbia

CHICAGO, Dec. 17—Formal notice of the cancellation of the license of the Dayton Motor Car Company, Dayton, O., maker of the Stoddard-Dayton car, to manufacture the silent Knight motor was mailed the receivers of the United States Motor Company, in New York today, by L. B. Kilbourne, of the firm of Knight & Kilbourne, holders of the patents. This step was taken in accordance with a clause in the contract which gives to the holders of the patents the right to cancel any license when the concern to which the license has been granted has become involved in litigation.

This cancellation does not necessarily mean the Knight engine can no longer be used by the Stoddard-Dayton people. They can continue to use the sleeve-valve but they must buy the motors from some other concern which is licensed to manufacture them. This also applies to the Columbia. It had been generally supposed that the Columbia company also was a licensee but such is not the case. The Columbia was supposed to buy its engines from the Stoddard-Dayton but this was not done, the Columbia making Knight engines at the Hartford plant.

This cancellation of the Stoddard-Dayton license leaves three concerns in this country with the right to make Knight motors, the Lyons-Atlas Company, of Indianapolis, the F. B. Stearns Company, of Cleveland, and the makers of the Edwards-Knight, at Long Island City.

Gray Patents in Holding Company

INDIANAPOLIS, IND., Dec. 16.—The Gray Engine Starter Company has been organized and will be a holding company for the patent rights of an invention of Thomas J. Gray on a self-starting device, the right to manufacture which has been let to the Gray & Davis Company, of Boston, a branch of the General Electric Company.

The Indianapolis company has been incorporated with an authorized capitalization of $300,000, the directors and principal stockholders being Mr. Gray, William Bosson and Dr. Robert C. Light, all of Indianapolis.

Court Orders Findlay Sale

TOLEDO, O., Dec. 16—Judge Killits, of the United States District Court at Toledo, has ordered the sale of the Findlay Motor Company's plant and equipment at Findlay, O., as the result of a petition filed against that company by the Ewing-American Motor Company. Fred Kruse, special master, is directed to sell the property for not less than $50,000 January 18 at 2 p. m. Of the proceeds the court will retain $1,500 pending adjudication of claims of the Lucas Machine & Tool Company, American Motor Company, and other creditors.

Roy D. Chapin, of the Hudson Motor Car Company, has been elected secretary of the Automobile Board of Trade, vice Benjamin Briscoe, resigned. John North Willys, of the Willys-Overland company has been chosen to the vacancy in the board of directors caused by the election of Mr. Chapin and the resignation of Mr. Briscoe.

International Gets Cash

Syndicate Pledges to Furnish $1,500,000 in Exchange for 6 Per Cent. Notes and 200 Per Cent. Common

Control of Company To Be Held by Lenders After Stock Issue Is Scaled Down Under Plan Adopted

MUCH misapprehension has resulted from the publicity given to alleged plans of reorganization of the International Motor Company without any substantial basis, but the facts in the case as here presented show that the rumors that have been circulated during the past 2 weeks are unfounded.

The situation is as follows: When the control of the company passed into the hands of the present operating company there was an excessive inventory. Business for the first 10 months of the calendar year covered orders for about 1,150 trucks of various types and the gross earnings were $4,500,000, with net of $335,000, or about twice the amount required for the regular preferred dividend and 90 per cent. more than in the corresponding period of 1911. But the working capital was not large and the merchandise claims on account of the inventoried material drew upon the capital account so that further financial help was needed to carry the company to a turnover.

A plan was worked out to secure between $5,000,000 and $6,000,000 for this purpose, embodying the idea of having some of the large stockholders take over the whole of an underlying issue of preferred stock and until 3 weeks ago it seemed certain that such a plan would be adopted. It was discovered after the plan had been arranged that there was a legal flaw in the proposal in that the minority stockholders were not given an opportunity to participate. Consequently the whole matter was abandoned and with only a few weeks in which to make a turn the management was obliged to devise another plan.

Under date of December 12, President C. P. Coleman issued a notice to the stock trust certificate holders in which he called their attention to the imperative need of $1,500,000 to continue the business and take advantage of its opportunities. Under the plan proposed, all stockholders have an opportunity to subscribe to the loan which will be for 1 year and bear 6 per cent. interest. Cash dividends on the preferred stock are to be suspended for 2 years, but the company is authorized to issue scrip dividends in place of the cash in case the earnings of the company warrant such procedure. The holders of common stock are requested to turn in their certificates and to agree to surrender 55 per cent. of their shares in order to provide a bonus to the financial interests who will advance the money. This bonus will be 200 per cent. in common stock as measured by the amount of the subscription. The scrip to be issued as dividends is convertible into preferred stock.

Thus if a stockholder of 100 shares, subscribes for $10,000 of the loan, he will participate in the syndicate operation to that extent and in addition will receive 200 shares of common stock in the corporation surrendering 55 shares.

The common stock is quoted nominally around $20 a share and the preferred around $64 a share.

The acquisition of $3,000,000 of common stock by the syndicate which has pledged the money, in addition to present holdings will be sufficient to place control of the company in the hands of the lenders, and while they are already represented on the board of directors the names of several additional representatives will be selected for the new board.

Vice-president Dickerman, of the American Car and Foundry Company, has been secured by the financial interests to make a detailed inspection of the properties of the company and will devote 4 months to the work.

The syndicate has selected a number of prominent executive men to carry on the work either in advisory or active capacities, but this does not mean necessarily that the present organization and its personnel will be radically changed for the present at least.

According to one of the directors of the company, the financial troubles have been due to an attempt to stretch out its working capital too thinly.

The reports recently formulated show that the assets exceed the liabilities and that the earning power of the company has been doubly sufficient to pay its dividends after settling all its operating obligations.

The addition of $1,500,000 in liquid capital to the funds of the company will serve to settle all current debts, complete the liquidation of the old inventory account which was inherited by the present company and leave about $700,000 free and clear for working capital.

Prospects for Australian Trade

SYDNEY, Nov. 25—The motor trade in Australia promises not to be quite so flourishing as that of the present season, owing to a depression in the money market, and the effects of the prospects there appeared at the beginning of the winter, of a drought, for although the dry spell only lasted 2 months, the loss the country sustained has been greater than was first realized, and the wool clip and the wheat crop are somewhat lower than those of previous years.

Both the wool and wheat are up to the usual standard, but the quantity is less.

The American makers who are aiming at developing their trade with Australia must bear in mind some of these points:

Not too heavy, anything over 2,500 pounds is considered to be very heavy; a good style of detachable wheel or rim will soon be absolutely necessary, as the makers of light British cars are doing this. A good finish and a good looking body.

Cars rated over 30 horsepower sound in most people's ears as something extravagant and only intended for the rich.

Makers of six-cylinder cars will not find a ready market for their cars, as there are very few sixes here even in the higher-priced European cars.

Right hand drive is absolutely necessary.

Clark Creditors to Hold Meeting

LANSING, MICH., Dec. 16—Notice has been given by Charles F. Poxson, of Lansing, appointed receiver of the Clark Power Wagon Company, in the Ingham County Circuit court, that all creditors are required to deliver their respective accounts and demands against the company to the receiver on or before January 28, together with proof by affidavit of the amount due. All persons indebted to the company are required to render an account of such debts and to pay the same to the receiver on or before January 28. All persons having in their possession property belonging to the company are required to deliver the same to the receiver on or before the date previously mentioned. All persons holding contracts with the company are required to present them in writing. A general meeting has been called for February 27.

Changes Made in Briscoe Staff

DETROIT, MICH., Dec. 16—Fred Aldis has become superintendent for the Briscoe Manufacturing Company to succeed George E. Farlinger, who resigned to become head of the Farlinger Manufacturing Company, which is to place upon the market an automobile radiator invented by him. Ed. Robinson succeeds Frederick C. Arthur in the sales department, Mr. Arthur also having gone to the Farlinger company. Both appointments are in the nature of promotions, Messrs. Aldis and Robinson having been with the Briscoe company for some time.

Use of Trucks in Mexico

Splendid Opportunities Offered for This Class of Trade in Place of Old Method of Transportation

Biggest Field for Motor Trucks Is Hauling Ore and Supplies in Different Mining Districts

CITY OF MEXICO, MEX., Dec. 9—In this capital, as well as in the other larger cities of the country, motor trucks are just beginning to be introduced. It is a virgin field and is believed to offer splendid opportunities for this class of trade. While there is some difference of opinion among the manufacturers and concerns that would be expected to find use for this modern vehicle as to whether it can be made to serve profitably in place of the present cheap laborers that are almost universally used as a means of carrying burdens in the cities and towns of the country, it is the general opinion that motor trucks will be found so much more serviceable than the old method of transportation that they will gradually be adopted.

In Mexico the licensed carriers of burdens known as cargadores take the place of delivery and other kinds of hauling vehicles except for the very heaviest articles. These men are able to perform remarkable feats of strength and endurance in the matter of carrying loads upon their backs. Owing to the cheapness of this class of service, modern delivery vehicles have found it impossible to compete with them. All baggage is carried to and from the railroad stations and hotels by these cargadores. They trot along the streets with heavy trunks upon their backs with as much ease and nonchalance as though the burden was of no weight. Whenever there is any moving of household furniture the work of transporting the articles from place to place is done by these men. Many of the largest stores, even those of large trade, make deliveries by this means. It is this cheap manual labor that has so far prevented an extensive trade being done in this country in the matter of selling motor delivery wagons. It is thought, however, that even this hindrance to the trade will in time be overcome as the cities of the country become more modernized.

In the matter of heavy hauling, such as is required by many manufacturing establishments and dealers, motor trucks are better suited to carry on the work expeditiously than the present method. When it comes to heavy machinery it is impracticable for cargadores to handle the different parts and the comparatively few trucks now in use in the country are employed for this purpose.

Biggest Field Is in Mining Work

The biggest field, however, for motor trucks in Mexico is that of hauling ore and supplies in the different mining districts. Already these vehicles are taking the place of wagons drawn by mules in many of the mining camps. But for the fact that the country has been disturbed by revolutionary activities for the last 2 years there would have been by this time many motor trucks in use by different mining concerns. Tentative orders for these vehicles have been placed and will be filled as soon as the country is in a state of tranquillity. There has been an evolution in the method of handling ore in the older camps. Originally the product of the mines was carried to the ore reduction mill or the railroad shipping point upon the backs of the peon laborers. In time this method gave way to the use of burros for the purpose and in many of the camps these patient animals are still serving as carriers of ore. Where it was possible to construct good roads it was found it was cheaper to haul the ore in large wagons pulled by mules and these latter are now being substituted by the modern motor truck. The evolution which has taken place in ore transportation is expected to be brought about gradually in the hauling of heavy articles in the towns and cities of the country.

During the last few years there has been inaugurated an era of street improvements not only in this city but in Guadaloupe, Monterey, San Luis Potosi, Puebla, Tampico, Vera Cruz, Chihuahua, Torreon and a few other cities of the country. Many streets have been paved in these different cities and it is now possible for motor vehicles of all kinds to be operated with a degree of smoothness that could not have been done prior to the making of these improvements. The accomplishment of this street paving has stimulated the sale of motor trucks as well as of automobiles and it is believed that it will not be long before there will be created a large demand for motor delivery vehicles.

Guatemala Fosters Automobiles

GUATEMALA CITY, Dec. 9—Action on the part of the federal government offering generous subsidies to any of the state of district authorities for the construction of roads will have a decided effect on automobile imports. No roads to be subsidized are to be built until the plans are approved by government engineers and no plan will be approved unless the roadway is to be constructed sufficiently well to permit the use of motor cars.

The successful use of motor cars in several sections of the republic has proven that great stimulus can be given many industries by the extension of such lines. This is especially true in the coffee districts where this method of haulage has proven most efficient. There are many isolated sections of the country not producing sufficient tonnage to justify the building of railroads, but as the cost of ordinary roadways is so much less and as they can be kept up with little expense the districts can be developed by the use of motor trucks.

Government engineers believe that the extension of good automobile roads will give the country most of the advantages of a widely extended railway system at one-tenth the cost.

Truck to Move Regiment to Coast

INDIANAPOLIS, IND., Dec. 16—A plan for transporting the Twenty-third United States Infantry from Fort Benjamin Harrison, near this city, to the Pacific Coast and return during the summer of 1913, using motor trucks for the trip, has been worked out by Col. Edwin F. Glenn and other officers of the regiment. The plan is to be submitted at once to the experts of the War Department for consideration, and if it meets with their favor Congress will be asked to appropriate $450,000 for the experiment.

Col. Glenn has long held a theory that the motor truck, in the very near future, is to take an important part in the mobilization of troops and in actual warfare. He believes the experiment to be proposed would be well worth the cost involved if it would establish the unquestionable efficiency of the motor truck for army work.

According to the plan worked out, it would require 140 motor trucks for the trip, and it is estimated the regiment could advance at the rate of 60 miles a day. The average daily march for infantry on foot is 15 miles a day, and for cavalry 25 miles.

Col. Glenn believes each truck could carry two squads, consisting of fourteen privates, two corporals, one surgeon and a driver, together with their necessary equipment and baggage. Additional trucks would be required for hauling gasoline, oil, tires, spare parts and other necessary things.

It is estimated that if a regiment were equipped with motor trucks, and internal strife developed within 600 miles of an army post, the regiment could reach the scene in much less time than it would require to assemble a railway train and transport the troops in this manner.

Statistics of the War Department show it costs $1,080 a day to maintain a cavalry regiment on march, at 25 miles a day. It is estimated a regiment using motor trucks could be maintained for $620 a day, and cover 60 miles.

Electric Car Men Meet

S. G. Thompson Delivers Essay on the Influence of the Central Station on the Vehicle Industry

Increase in Numbers of the Electric Pleasure Car Has Been Continuous—Truck Growth Recent

THE December meeting of the Electric Vehicle Association of America was held Tuesday evening at the Engineering Societies Building and about fifty central station men and electrical engineers attended to hear the address of S. G. Thompson, of the Public Service Electric Company, of Newark, N. J., who delivered an essay on Central Station Influence on the Electric Vehicle Industry.

Mr. Thompson presented figures, data and conclusions showing the prime value of electric vehicle business to the central stations and outlined what had been done to foster the vehicle business by his company and its effect upon earnings during the past 2 years.

He treated particularly of electric trucks and showed that at present vehicles of that type represent 26 per cent. of the total power wagons operated in the territory served by his company. The figures are 731 trucks of all kinds, and 191 electrics. He showed that only nine manufacturers of electric trucks are represented by the 191 vehicles in service.

Gas Versus Electric Trucks

Comparing the high grade gasoline trucks with the electrics he showed that 185 of the gasoline trucks cost more than $1,000 and represented ninety-eight manufacturers, thus giving the electric trucks more than 50 per cent. of the high grade business.

In part his paper was as follows:

Probably no better example of the influence of the central station on the electric vehicle industry exists than in those sections of New Jersey served by the Public Service lines. Two years ago this territory presented a virgin field for electric vehicle exploitation. The manufacturers themselves were but casually attempting to market their product, and the public at large was not sufficiently informed of the merits of electric vehicle operation to take kindly to its adoption. Aside from a few commercial vehicles operated by manufacturing plants and by New York business houses, but few of these machines were in use, and, with the exception of those power wagons owned by the Edison Storage Battery Company and allied interests, there were no large installations in the state. Pleasure vehicles had met with little favor, there being a total of but eighty machines—many of an ancient type and nearly all but infrequently used.

An investigation of the electric vehicle conditions in those cities which were leaders in the use of these machines influenced the Public Service Electric Company to attempt their introduction in its territory, and for that purpose an automobile department was established, whose accomplishment in the introduction of vehicles is represented in the increase in the number of vehicles since the inception of this department.

The increase in the number of pleasure vehicles has been practically continuous. This is accounted for by the fact that the attitude of the Public Service company immediately influenced the manufacturers of these machines to engage actively in marketing their product in this territory.

The commercial vehicle increase is shown to be of a slower growth during the early period of activity, while the rise in the last few months is quite marked. This is a natural condition, as the development of power wagon use necessarily required a longer introductory period of education than that of the pleasure machines.

An analysis of the power wagon conditions in this territory today discloses some rather astonishing facts regarding the status of the electric commercial vehicle, and if these conditions may be accepted as an indication of the general trend throughout the country, we need have no fear for the future of the electric commercial power wagon industry.

At the present time we find a total of 731 commercial vehicles of all types employed within this territory. From the curve it will be observed that 191, or 26 per cent. of these are electrics. The balance are gasoline machines. As this 26 per cent. in electric machines represents the produce of but 9 vehicle manufacturers, while the 74 per cent. of gasoline machines were marked by 158 makers, it would appear that the electric vehicle manufacturers are certainly obtaining their full share of the total power wagon business.

If we go further into the analysis of these figures, we discover that of the 540 gasoline machines in operation, 355 are low-grade cars whose selling price is in the neighborhood of $1,000. In this class are represented sixty vehicle makers, while the balance of 185 gasoline cars are the product of ninety-eight different companies. In other words, over 50 per cent. of the total number of high-grade power wagons employed are of the electric type. Let me impress this statement upon you more strongly. Nine electric vehicle manufacturers, in competition with ninety-eight gasoline makers, have marketed 50 per cent. of the total number of machines of similar quality employed within the territory under discussion. Under the circumstances it would appear that the acceptance of the gasoline power wagon is the influence of numbers rather than of quality or of possible application.

The increase in kilowatt consumption and income will appeal strongly to the central station manager; it indicates just what the use of power wagons means to his department.

It will be observed that the rapid increase in power consumption follows a marked increase in the use of commercial vehicles, and points to the fact that the introduction of these machines is of far greater importance to the central station than is that of the pleasure vehicle.

The decrease in the average kilowatt-hour rate from 4.15 to 3.35 cents, is attributable to the fact that a majority of these commercial power wagons are in the larger installations and public garages, paying for their service at the wholesale power rates. The rates have not been lowered.

Rise Throughout December

While my figures are to December 1, it is interesting that the indications point to a continued rise throughout December because of the vehicles which have been sold, but are not yet delivered, and assurances of additional business from cars not now charged from the Public Service lines. In these are included some forty machines of the commercial type.

It is evident from the foregoing that the influence of the central station on the electric vehicle industry is far-reaching in its results, and from reports of the vehicle manufacturers themselves, I have every reason to believe that educational campaigns in other sections have produced a marked increase in the number of electric commercial vehicles employed. I am strongly of the opinion that if central station managers would make a market investigation of the local conditions, with a view to promoting the use of electric power wagons, they would find the field to be much larger than is generally believed; and, further, that the business can be secured with a very reasonable expenditure of money. This is borne out by the fact that in the operation of our automobile department our income has always exceeded the amount expended in promoting the use of electric machines, and we shall finish the year 1912 with a good profit. From our experience and our faith in the future of the electric vehicle, we feel that the ultimate wholesale introduction of power wagons can best be attained by continued effort along the lines which we have pursued during the past 2 years, rather than through extensive expenditures of a more or less speculative nature. Possibly we are wrong in our premises, but at any rate it is good business procedure.

Mr. Thompson's address was illustrated with two slides showing series of curves outlining changes made in the electric vehicle business in his territory in 2 years and its relation to the sale of current.

Mr. Thompson's presentation was greeted with astonishment by many of those present and the discussion brought out only a few sidelights on the paper.

One of the interesting things that developed was a statement by Mr. Hillman, of the General Vehicle Company, that careful scrutiny of the central station field shows that the average annual return from the investment represented per kilowatt used in the business of charging electric trucks was $156 while no other class of business approached that figure. He said that the saloon business was next in order of profit but that it was much lower in returns. He concluded that as the business was so profitable it should be fostered.

A rather amusing point was brought out during the discussion when a New Jersey delegate told a story on himself that provoked much laughter. He said that he was soliciting a potential user of current and was about to close the contract when the prospect noticed the car in which the Jerseyman had ridden to the door.

"Hey there," exclaimed the prospect, "if electric vehicles are so good why don't you use one yourself; I see you have a gas car."

The Jerseyman had to admit the palpable fact and the contract is still unclosed.

This led to a discussion of the abandonment of gasoline automobiles by the big electric companies. The expressed opinion of many of those present was that the gasoline automobile would not be abandoned by the companies where its service was more economical and efficient than the electric.

The next meeting of the association will be held January 20. A banquet will be tendered the past president, W. H. Blood, at Delmonico's, January 16.

Tradesmen to Form New York Club

Plans for organizing automobile men of New York into a club along broader lines than the Automobile Club of America, are making progress. The first call was made October 1 by E. E. Schwarzkopf and since that time 122 names have been added to the list of founder members. Those who have identified themselves with the movement include leading dealers, officers of the national organizations and members of the motor and accessory trades.

The preliminary list shows that the new club, which will be called the Automobile Club of New York, is to be an association of the automobile industry. Sidney S. Meyers has been named counselor.

The objects of the club as announced in its prospectus are as follows: To provide a social club in the neighborhood of Columbus Circle; to stimulate public interest in the automobile; to cultivate closer relations between the trade and the users; to secure the advantages of co-operation and to provide a center of information and advice.

Enthusiasm at Cadillac Convention

DETROIT, MICH., Dec. 16—The convention of Cadillac dealers came to a close with a big banquet at the Ponchartrain Hotel, at which K. P. Drysdale, advertising manager of the Cadillac company, was toastmaster. During the four days' sessions, which were held at the Ponchartrain, points of general interest along the lines of salesmanship were discussed, and especially plans for service to the owner. Trips through the factory were arranged for the dealers in small parties. About 250 were in attendance, about 200 of these being dealers and the others men connected with the various agencies, all parts of the United States and Canada being represented.

Hoosier Clubs Organize

Local Bodies Combine to Form Indiana State Automobile Association to Be Affiliated With the A. A. A.

Motor Dealers' Contest Association Meets—Mutual Insurance for Wisconsin Automobilists

INDIANAPOLIS, Dec. 18—(*Special Telegram*)—The Indiana State Automobile Association has been formed by representatives of the various automobile clubs of the state. Clubs which have a charter membership in the state organization are the Hoosier Motor Club, of this city, the Salem Automobile Club, of Salem, the Madison Automobile Club, of Madison, the Terre Haute Automobile Club, of Terre Haute, the Winchester Automobile Club, of Terre Haute, and the Evansville Automobile Club, of Evansville. Officers of the organization are: President, P. C. Rubush, an Indianapolis architect and vice-president of the Hoosier Motor Club; first vice-president, W. A. Koch, president Evansville Club; second vice-president, Samuel Lane, president of the Hoosier Motor Club; third vice-president, Samuel Lane, president of Terre Haute Club; secretary-treasurer, W. S. Gilbreath, secretary Hoosier Motor Club. The State Club will be affiliated with the American Automobile Association. A. G. Batchelder, chairman of the executive committee of American Automobile Association addressed the meeting at which the club was formed.

Dealers' Contest Association Meets

The Motor Dealers' Contest Association held an informal meeting at the Elks clubhouse Friday, December 12. About thirty were present. It was decided to hold its meetings on the first Monday of each month. A discussion arose as to the advisability of the name decided on at the last meeting, it being shown that there was a prevailing opinion among the trades people that the organization was for racing only, and after a few extemporaneaus speeches on that subject by different members, it was decided to send out a circular to the various agencies throughout the city, showing that the plan of the organization was to conduct contests only for the welfare of the industry in New York City. Twelve committees were appointed. The election of offcers and the adoption of the by-laws and the constitution will take place at the next meeting of the directors.

Mutual Insurance for Motorists

MILWAUKEE, WIS., Dec. 13—The first Wisconsin insurance company catering exclusively to owners of motor vehicles has just been organized at Juneau, Wis., under the style of Motor Vehicle Mutual Insurance Company of Wisconsin. The headquarters of the company will be at Juneau, where offices have been established at the Citizens' Bank Building. The officers are: President, Edward T. Heinemann; vice-president, Louis C. Pautsch; secretary, H. A. Henning; treasurer, Peter Peters. It is interesting to note that the principal figures in the new mutual insurance project are officers and moving spirits in the Juno Motor Truck Company, of Juneau, Wis., manufacturing the Juno commercial car, formerly the Brodesser, of Milwaukee. The Motor Vehicle Mutual Insurance Company begins operations with about 100 policies in force and excellent prospects. It will engage in direct competition with the stock companies, which are charging approximately 2 per cent. for protection from fire and 1-2 per cent. for protection from theft. The mutual rates will be considerably lower, in fact, bearing the same relation to old line rates as do ordinary fire risk rates of the mutuals and old line companies.

Undue Prominence of Winnipeg Agricultural Motor Contests Sidetracks Design of Interest to Automobile Industry, Says Prominent Critic—Example of New Window Lifts—Long Stroke Valveless Motor of Revolutionary Efficiency

DESIGN of Agricultural Motor Implements.—In proportion as the business world is accepting the motor vehicle as indispensable for commercial transportation work, the still larger field which awaits the automobile industry in the manufacture of self-propelled and power-actuated tools for the cultivation of the soil begins more and more to engage the attention of those designers and manufacturers who would rather build up a new kind of automobile manufacture than struggle against an already established and strong competition in the making and marketing of pleasure cars. With regard to the opportunities which exist in this new field—destined to become larger than that of the motor truck, according to the views voiced in Europe—K. von Meyenburg, who is recognized as a leader in the manufacture of light farming machines equipped with tools of new types which till the soil in new fashion, brings out some interesting viewpoints in an article dealing with the arrangements for comparing the merits of competing machines at the trials held at the third agricultural exhibition at Winnipeg, Canada, this year. He denies that these competitive trials, or those held in 1908 and 1909 at the same city, which is the world's center of agriculture by motor power on a large scale, have had any effect to demonstrate the value of small motor-driven machines for meeting the general needs of farmers.

The great steam tractors and plows have been of inestimable service for western Canada, he admits. Thousands of miles of new railways have followed their tracks. Villages, towns and cities have sprung up like mushrooms, and factories are being built all over this northwestern country which the motor plow had opened up. By its aid this empire was colonized at the turn of a hand. And millions of acres of virgin soil still await the breaking-plow before the "last West" will be under cultivation. In this work there are still ample opportunities for continuing to prove the special utility of the large tractors.

A much more important work is reserved for motor power in general, however, as an aid in maintaining the fertility of all the old farming area. Intensive cultivation is the refrain of all who have the slightest interest in agriculture and of all who have watched with deep misgivings the marked reduction in the yield per acre which everywhere, lately, accompanies the insufficient working of the soil, itself the result of insufficient and high-priced farm labor. The remedy which is usually recommended consists in work, many different forms of work and nearly all requiring tractive power and tool-working power, but where shall this work come from if not from the motor machines of small power which are the only ones which may be made suitable for the average farmer's conditions and for the kind of work which is required in intensive cultivation?

The competitions at Winnipeg have given no clue whatever as to what the farmer can do with motor machines for this class of work. They were highly important of their kind but they were heralded all over the world as the best occasions for obtaining reliable information with regard to the design and sizes of motor vehicle machines for general farm work. They have been very misleading, for this reason.

The plowing tests this year were somewhat more extensive than in 1908 or 1909, but they were not sufficient for proving or disproving the reliability of the competing machines. If all the six days of the trials had been used for preparing an area for seeding, from plowing to drilling, there would have been obtained not only useful figures on fuel cost and area-efficiency but it would have become possible to show farmers reliability figures and the adaptation of the machines to many different forms of work.

There were fewer entries than in 1909, but this was offset by a larger number of new types whose work at the trials was awaited with tense interest. The double-opposed two-cylinder type of motor was represented for the first time, coming from the automobile camp. Three firms had been using this style of motor in four different machines, but unfortunately two of the firms withdrew their entries during the last month—the 45 horsepower I. H. C. and the 25 horsepower Avery—leaving the field to Goolds, Shapely and Muir. A crude-oil motor was shown for the first time; namely the "Oil-Pull" of the Rumely company, but the Hart-Paar company could not be induced to place its crude-oil machine in the field against it, and no comparison could be had. The Gas Traction company of Winnipeg had built a machine in which great local expectations were centered. The I. H. C. met up with its two-cylinder motors, and among the steam tractors there was a Case machine of nominally 12 horsepowers which it would have been interesting to see pitted against the gasoline motors of about equal power; but it was alone in class D, and no comparison could be made under the rules. Kinnard-Haines brought two of his high-wheeled 40-horsepower machines. Of the same high-wheeled type were the machines of the Gas Traction company of Minneapolis which were considerably stronger than those built in Winnipeg. The Avery farm wagon made itself noticed, circulating like an errand boy over the testing ground and giving good service. The Birrell motor which came too late in 1909 was on hand this year.

The point plan according to which prizes were awarded was as follows:

At the brake test: 100 points for motor power per fuel unit; 10 points for water consumption divided by tractive power; 10 points for average steam pressure; 10 points for steadiness in running, vibrations and general behavior; 20 points for horsepower-hours per 100 gallons of water, and 20 points for drawbar pull divided by brake horsepower.

At the plowing test: 90 points for fuel consumption per horsepower-hour for plow-pull; 30 points for water consumption per horsepower-hour of plow-pull; 20 points for acreage plowed per brake horsepower-hour; 10 points for the quality of the plowing; 15 points for ground covered with one load of fuel; 15 points for general behavior, troubles, etc., and 50 points for design, construction and workmanship.

From this it may be seen that practically everything depended upon the maximum power developed during one-half of an hour at the brake test. On the other hand, the real interest was centered in the actual work. It swarmed with manufacturers, engineers, agents, representatives, editors and farmers, and they all wanted to go to the plowing field to see "the real thing."

Out of the over-rich tabulated material which resulted from the competition no figures can be compiled which do not relate only to the average local soil condition. The old prairie turf, which was mostly in question, is easy on the heavy machines in not causing the wheels to sink in or the plow shares to jump out. The conditions of general farming are widely different, and those who would build motor plows must know where they will be able to sell them, as the soil conditions must determine the type and the size. Two-thirds of the tillable area of the earth comes in the class of semi-arid land where dry-farming must be resorted to, and the customary farming tools are not adapted for this work. Motor tools must be developed for it. Germany, though known as a country of many large country estates, has according to the statistical yearbook only 23,000 farms of more than 100 hectares and comprising a total of 7 million hectares, where the machines of great size, power and weight might be applicable to a part of the work, but she has 260,000 farms of from 20 to 100 hectares, comprising in all 9 million hectares, and one million farms of from 5 to 20 hectares, totalling 10 million hectares. France has even a much lower percentage of farmers who control more than 100 hectares, and in America there are 5 million farmers who have from 40 to 100 hectares [1 hectare equals 2.4 acres].

The chance of having the motor-plowing on these millions of small farms done by association and, in this manner, with large machines and tractors, is remote, because plowing depends far more on weather and season than threshing does. Those who would nevertheless build tractors should copy the Americans and build them large. In England, where the Joel & Saunderson small tractors are better known than the Stock tractor is known in Germany, only the types weighing from 5 to 8 tons are making headway.

In America the tendency is now to change from the motor running at 250 to 350 revolutions per minute to upright four-cylinder motors running at 700 to 1,000 revolutions—again under the influence of the automobile industry—and to try to reduce the gross weight of 300 kilograms per horsepower for the agricultural machines to 200 or less.

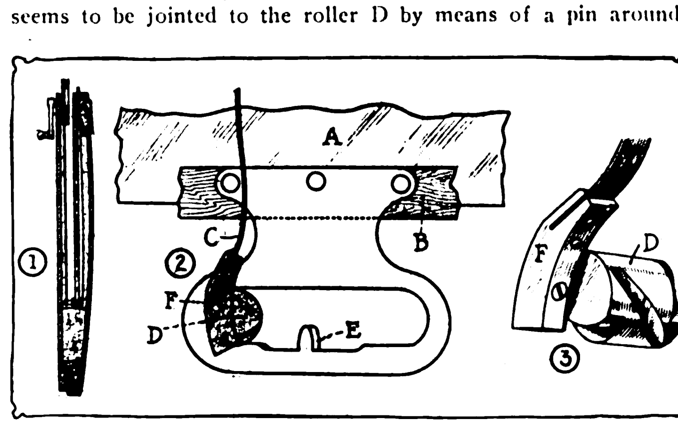
At a weight of 200 kilograms per horsepower, from one-half to two-thirds of the power is required for moving the machine; frequently much more. A speed over the ground of 1 meter per second is a good average. It would be inadvisable to gear to a lower speed, trying to utilize a larger percentage of the power for work, as in that case the wheels would simply skid. And if a higher speed than 1 1-2 meter per second is used in a plow-field, both man and machine suffer. The computations which are offered of the cost of motor-plowing are mostly illusory, and those relating to the required dimensions of wheels, with a view to the calculation of rolling friction, neglect the essentials, which are always the nature and condition of the ground. At all events the question of adhesion overshadows that of power consumption. As the farmer is a plant manufacturer he will eventually measure the cost of motor-plowing not by the cost per acre but by the crops he gets after it, and from this point of view the aim should be to plow better rather than to plow cheaper.

Those who would build motor plows should first study thoroughly all the existing forms, and still more thoroughly those which have already disappeared as well as the evolution through which the existing forms in each case have passed. Then he should study plant life and the local peculiarities of the farming to which he intends to cater. He should not blindly transfer his automobile experiences upon motor plows, for the step from rail and train to road and automobile is a far shorter one than that from road and automobile to field and plow. Let him first read Greig's official report of the three motor plow competitions at Winnipeg and go thoroughly through all the text, illustrations and tables.—From *Der Motorwagen*, Nov. 20.

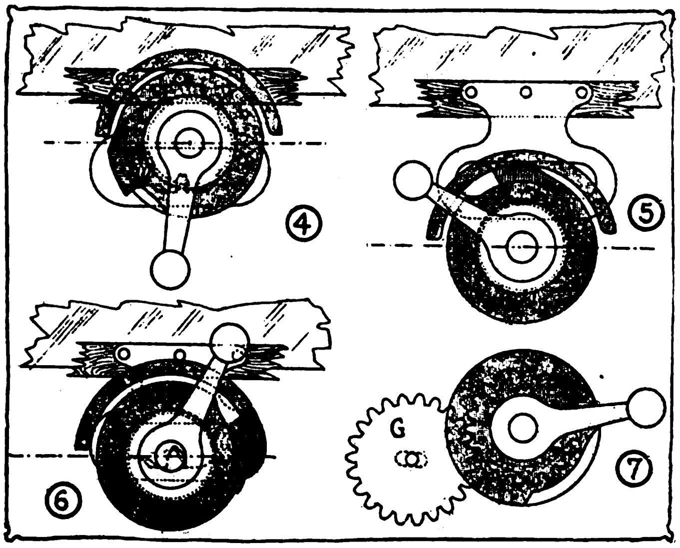
WINDOW Lift and Adjuster.—Since the unframed plate glass windows for closed automobiles have come into fashion, the little but not insignificant problem of raising and lowering these windows with perfect ease and of adjusting them at any desired degree of opening has entered upon a new phase, partly by reason of the general tendency to adopting something more luxurious than that which has been used for ages in ordinary carriages, and partly because the unframed window leaves some spare room in the slot-space of the door in which a mechanism may be introduced which will do the required work more simply and with less effort than when it is done by hand and with one of the old-time straps with the traditional leather grip or tassel which in course of time becomes soiled and unsightly, not to say unsanitary.

A new French device, called the Hera window lift, embodies an interesting solution of this problem in luxuriousness, and it has appeared sufficiently final to the well-known Rothschild firm of carriage body builders in Paris to warrant its adoption, while its ingenious cam movement appeals directly to the mechanical connoisseur. The object of the designer was to produce a thin and reliable mechanism which would transform an effortless and continued simple movement of a weak hand into (1) the raising of the window to above the level of the lip on the sill of the door frame, (2) the outward push by which this lip is cleared and (3) the short drop by which the window comes to rest on the sill outside of the lip; and it was furthermore necessary that the mechanism should be located below the sight face of the glass. A simple reversal of the movement should slowly and deliberately reverse these three movements, without danger of the glass dropping to the bottom of the slot-space, and, during either the up or the down movement it should be possible to stop actuating the mechanism with the result of having the window stay just where it was when the mechanism ceased to be operated.

Among the illustrations, Fig. 1 represents the lower part of a coach door and shows how an ordinary crank-and-pulley lift would be quite inadequate for the purpose in view; it would not lift the window high enough and would not push it out over the lip even if a rack were employed to make the lift sufficient. Figs. 2 to 7 show parts of the mechanism actually used for accomplishing all the desired movements. To the lower edge of the window pane, or to its frame B if one is used, a sheet steel plate is secured, in which there is formed a horizontal slot whose lower edge is of a certain cam formation serving to make the roller D move transversely as it is moved from one side to the other in the slot. Especially, the dog E serves to turn the roller completely around by entering the oblique groove formed in the latter, and as the dog advances in this oblique groove, the plate and the window pane are gradually pressed away from the guide block F, and as the latter cannot move inward, being flush with the inside panel of the door at the moment when this movement takes place, it is the window which must move outwardly. It is thus the dog E which makes the window clear the lip on the window sill. The guide block F seems to be jointed to the roller D by means of a pin around



Figs. 1, 2, 3—Design features of Hera window lift



Figs. 4, 5, 6—Successive steps in operation of Hera window lift. Fig. 7—Provision for easing lift and drop

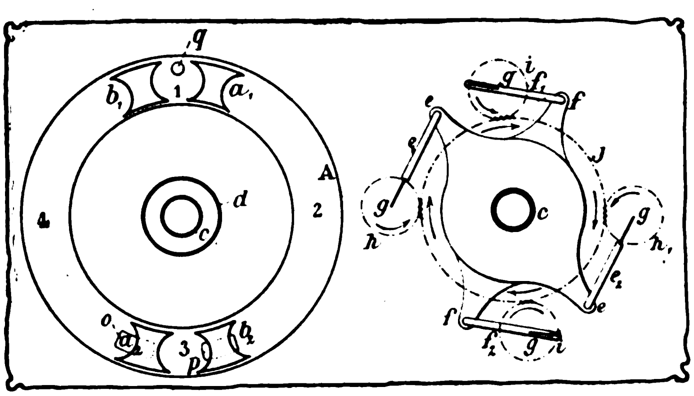
which the roller can turn. It is hung from the pulley by the tape C, which seems to be the same kind of very thin metallic tape that is used for bracing aeroplanes. An examination of the plan for operating this window lift shows that this tape must be of strictly unvarying length in order to have the three stages in the operation which are represented in Figs. 4, 5 and 6 materialize faultlessly. At all other stages of the operation the window is simply suspended from the pulley by the tape and resting upon the roller D—as in Fig. 2.

It is stated that an "autoloc" prevents the tape from unwinding by the weight of the window, by pressure brought to bear upon it or in fact by any other mode of operation than that of turning the crank backward, but the mechanical nature of this "autoloc" is not explained.

Fig. 4 shows the position of the parts at the moment when the window has been hoisted up so far that the guide block for the roller gets into engagement with a cam disk which is mounted upon the same shaft with the pulley and is formed with a circumferential cut-out in which the guide block finds lodgment. Thereafter, until the end of the movement, the guide block with the roller is turned around with the cam-disk, being held against it by means of a semi-circular guide secured upon the door panel, and when the crank is turned in the opposite direction, to lower the window, it is this position of the guide block between the cut-out and the semi-circular guide—and not the connection with the pulley by the tape—which compels the guide block and the roller to follow the crank movement.

Fig. 5 represents the moment when the window has been raised above the level of the lip on the sill and when the dog E, by continued turning of the crank, turns the roller around on its pin, thereby shoving the window outward as explained before, and Fig. 6 shows how, by turning the crank still a little farther around, the window is set down upon the sill outside of the lip. As the roller is now at the end of the slot the crank can be turned no farther in the same direction. Fig. 7 indicates the method adopted for reducing the effort required for the operation of the device. To the spur wheel G is secured one end of a spiral spring and this is wound by means of a similar spur wheel on the pulley shaft whenever the window is lowered, the weight of the window acting as the power. When the crank is turned in the other direction, to raise the window, this power, now stored in the spring, is returned in part and assists the hoisting movement.—From *Omnia*, November 30.

[The Rawlence window lift shown at Olympia and based on the use of strong coil springs, an extension rest—of the lattice-work pattern widely used by physicians and dentists—and an operating button secured in the upper part of the window pane, supplies another intimation of a public want with regard to the perfecting of window lift devices.—Ed.]



Figs. 8 and 9—Diagrams indicating main working principle of the valveless 60-horsepower Esselbe motors

New Motor Types—The valveless 60-horsepower Esselbe (S. L. B.) motor weighing 35 kilograms attracted much attention at the recent aviation show in Paris. Its general design bespoke for it a possible application to other than aviation purposes and suggested that its lightness might be found consistent with reliability without the constant and superlative maintenance care which must be bestowed upon the high-powered aviation motors with rotary individual cylinders grouped in star formation. The principle of its operation may be partly understood from the following description and the accompanying diagrams, Figs. 8 and 9.

On a common axis which is perpendicular upon the planes of the two diagrams there are mounted, first, a hollow ring-shaped body or tore which is provided with external cooling flanges and constitutes the motor "cylinder," in so far as it acts as the furnace for internal combustion and two pairs of pistons of special shape have a reciprocating movement in it, each piston covering an arc of somewhat less than 90 degrees while the tore in which they move is rotated at the same time; secondly, a stationary casing enclosing the mechanical organs which are instrumental in timing the rotation, though they receive the impulsions to this effect from the explosions taking place inside of the rotated body. Fig. 8 is a section through the middle of the ring-shaped body or tore A. The two pairs of pistons *a1*, *a2* and *b1*, *b2* are secured respectively to two plates *a* and *b* (not shown) which are made integral with the two concentric tubes *c* and *d*. [The exact form and position of these plates is not made clear, but it seems that they must be in juxtaposition, one being mounted upon tube *d* and the other upon the inner tube *c* the latter projecting beyond the end of *d*, and that these plates must be in constant sliding contact with the interior edges of the tore, which is formed in two parts bolted together.—Ed.]

The tubes *c* and *d* constitute the axles for the rotary and reciprocating movements of the plates *a* and *b* and, farther back, carry the cross-beams *ee* and *ff*, Fig. 9, to the ends of which are jointed the connecting-rods *e1*, *e2* and *f1*, *f2*, which by means of small crankarms *g*, mounted in a stationary casing which protects the whole mechanism, actuate the gear pinions *h*, *h* and *i*, *i*. These pinions mesh with a spurwheel *j* of twice as large diameter, whose movement is transmitted bodily to the tore A by means of a tubular connection not shown in the diagrams [but which it seems must enclose the two tubes *c* and *d*]. For each stroke of the pistons the tore thus makes one-half of a revolution, which brings the exhaust port *p* into the position at the end of the stroke where the spark-plug *q* was at the beginning. The tube *c* communicates at one of its ends (the rear) by means of an attached tubular connection with the carbureter, while its other end communicates by means of an annular space and the admission port *o* with the interior of the tore. The

Criticisms of Non-Poppet Valves To-Date

Critical Review of Present-Day Engineering Practice in the Construction and Design of Various Types of Rotary and Sleeve-Valve Motors in Europe and America—Essential Features Discussed

Most Notable Developments Have Been Made in Rotary Valve Motors—Chief Feature Is Protection of the Valves from High Temperatures—Some Ingenious Means for Water Cooling

By Eugene P. Batzell Installment I

THE past year marked a notable step forward in the field of non-poppet valve motors, because it witnessed that state of development when a number of makers found it practical to put their line of such motors on the market. New inventions and constructions in this line continue to appear, but only in a few cases do these possess any merit.

The sleeve and piston-valve engines have added some to the number of their followers, but the most notable developments have been made in the rotary-valve motors. This latter type of valve seems to be a favorite with American inventors. The chief feature of the present trend in rotary-valve design lies in valve protection from high temperatures. It is being accomplished either by preventing the valve from getting much of the heat from the combustion or by providing intense cooling of the valve. The correct operation of rotary valves of the barrel type is extremely sensitive with regard to the permanency of clearance around the valve. The shape of the valve and the amount of clearance can be retained only through a small temperature range.

In this respect the disk-rotary valve has shown itself less troublesome. On the other hand, the circumferential speed and the pressures between the rubbing valve surfaces have only secondary importance, because they remain far below those permissible for lubricated bearings. Nevertheless, the operation of rotary valves causes trouble as long as the valve temperature is high. Low bearing pressures, low bearing velocity and low temperatures go hand in hand to facilitate the valve lubricating problems, but judging from past and present experience with these valves it is of much greater importance to keep them comparatively cool than it is to further reduce their bearing pressures or circumferential speed. The valve which undergoes but little change in its temperature not only removes much uncertainty in regard to its lubrication, but, what is more important, its general functioning can remain at its highest efficiency, with uniformity as a result. Such a condition can be established from tests or otherwise, and it is for the motor designer to plan his construction so that these conditions will prevail unaltered.

Thus far better success in practice has followed the rotary valves with intense cooling; there are fewer representatives of the heat-protected valve type. The Henriod Darracq motor belongs to the latter class with a barrel-type valve. In this motor some of its power and efficiency is sacrificed to protect the valve against the highest pressures and temperatures of combustion, which is accomplished by letting the motor piston overtravel the valve port near the end of its stroke. By this means the valve is shielded effectively when the spark is properly advanced, but it has little value when running on a retarded spark, because the moments of highest pressure and temperature can be shifted beyond the instant when the piston begins to uncover the valve port. In the hands of an average driver this can occur frequently, reduc-

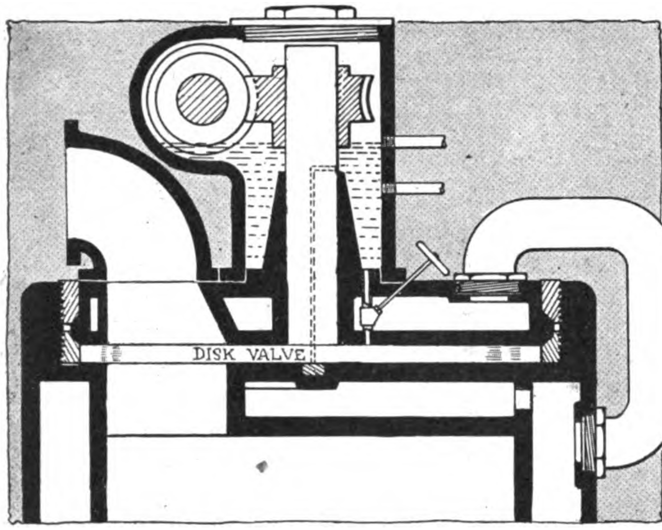

Fig. 3—Section of Beck disk-valve motor

ing considerably the practical value of the basic principle of this invention.

Another representative of the shielded valve belonging to the disk-valve class is the Beck type, Fig. 3. Little can be said in regard to this construction and practical results with the same at present. It seems, however, to remove all the objections attached to the unprotected-disk valve, when used for high-compression and large-bore engines. Not only does it keep the valve cooler, but it removes also some of the presssure on it and consequently simplifies the valve drive problems associated with disk-valve motors. It is known that the unprotected-disk valve requires a considerable amount of driving power due to its large surface exposed to the cylinder pressure.

Reviewing the rotary valves with intensified cooling one must acknowledge the Itala construction with internal water cooling, Fig. 2, to be the best so far accomplished. Objections can only be raised against the arrangement for water-cooling the valve, in that the water passes it on its way from one cylinder into the other. Though each valve cannot cause a great change in the water temperature, nevertheless, the cylinders will have different temperatures and therefore different actions. It would be better to have the cylinders at even temperatures so as to prevent unequal expansion which may affect the valve operation. However, practice does not seem to have disclosed any marked disadvantage with the existing cooling system of this motor, which otherwise has great merit in the arrangement of joints for the water where entering the valve and leaving it.

Experiments have shown that a comparatively large clearance around the valve would not interfere with the operation of the motor so long as it is not great enough to allow an escape of gas between adjacent cylinders, but any clearance, even a very small one, cannot stop the spreading of the gases to a certain depth from the valve port zone, which interferes with the lubrication of the valve bearing in that space. A very small clearance of .002 inch or below cannot be considered sufficient for more or less heated cylindrical valves. The larger clearance which is essential for the proper functioning of a long valve would be followed by a corresponding wider spread of gases into the valve bearing zone and consequently by more trouble, unless this spread is stopped by some means.

From facts revealed by different rotary-valve systems it is certain that the straight, smooth cylindrical valve is unsatisfactory, and that other means are required besides the small clearance around the valve to keep the latter in the best working condition. The spreading of the gases from the valve port zone into its bearing zones is particularly harmful and must be prevented in every case. The Itala valve illustrates this point, Fig. 2. Expansion rings are employed to prevent the lengthwise spread of gases and also to keep the working valve surfaces protected from the outside harmful influence of foreign matters, such as dusty water, etc. Good results are obtained when leaving these rings free on the valve, not anchoring them to it, so that when expanding they take hold of the outside surface and remain stationary though the valve rotates. A good labyrinth type of packing is effected in this manner, and considering it as such, it is better to have narrow rings, but of a greater number than a single wide ring in the same space; nevertheless, one ring is better than none and if space is restricted or if the valve is of small diameter a single ring might be sufficient.

Referring to the Henriod-Darracq method of preventing valve leaks by employing circular and longitudinal grooves on the body of the valve, in which the oil is supposed to accumulate, one is obliged to consider it inferior to the construction with rings. Judging from other instances when grooves are used on rotating shafts they become clogged up in time by any kind of solid foreign matter which has a chance to penetrate therein, unless the grooves are continuously and vigorously washed out. In valves of the Darracq type the exhaust gases will invariably fill up the grooves with carbon and other solid deposits, filling first the grooves nearest to the ports, thus not only their beneficial influence is reduced, but there is a danger of the valve sticking should some of the accumulated solid mass in them become loose.

As stated above, this deduction is drawn from observations made elsewhere, but it would be of great interest to hear on this point from the Darracq company. Anything like the above objection has little reason to be anticipated where expansion rings are used, because the solid particles have to work into the labyrinth against the tendency of valve rota-

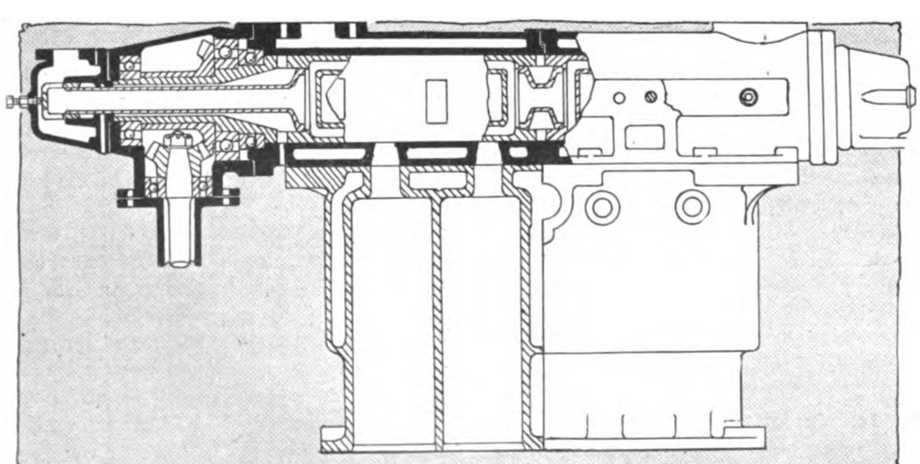

Fig. 4—Sectional view of Castiglione and Bolton rotary-valve motor

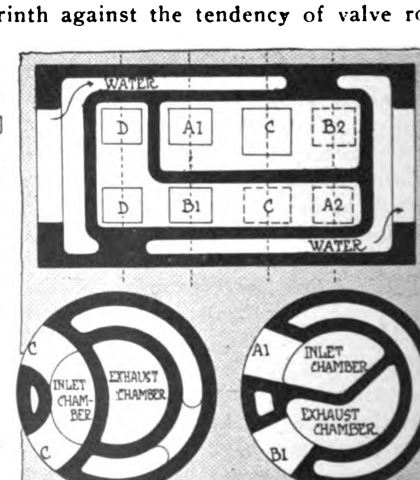

Fig. 5—Castiglione and Bolton valves

tion. Moreover, the labyrinth passages are effectively cleaned by the oil overflowing from the bearing between the rings, whereas the open grooves are merely touched by this oil flow which remains at the extreme of the valve clearance.

The Itala valve is a good example of what can be accomplished by employing a cooled valve while retaining comparatively high bearing pressures. The valve itself, though large in diameter to give a proper size of opening at one-quarter crankshaft speed, nevertheless does not interfere with a clean design of the motor, Fig. 1.

A rotary-valve motor of recent English origin, Castiglione and Bolton, Fig. 4, can be given credit for the thoroughness of working out in the details of internal water cooling for the valve, together with the means employed to lead the water in and out without any dangerous leaks. Any water leak must be considered dangerous if it is apt to occur so that the water penetrates into the lubricated valve bearings, as it is more than likely to cause the valve to stick. The motor, Fig. 4, is provided not only with stuffing-boxes at the places where the water connects with the inside of the valve, but also has separators for the water and oil, which, notwithstanding the stuffing-boxes, might still leak through. These separators should reduce to a minimum the chance of having water interfere with the lubrication of the valve. On that the merits of this system practically stop. It is difficult to see an advantage in the rather complicated shaping of the valve and its inlet and exhaust passages, Fig. 5. The large valve diameter, the valve drive, etc., result in a motor of great bulk entirely inappropriate for automobile use, and it would require much simplifying to make it attractive.

In connection with the foregoing motors a special point has been made of the arrangement of connections for internal valve cooling. It is of great importance to have the water separated from the oil valve lubricant and on this basis the construction of the Von Bottweiler motor, Fig. 6, cannot be given much credit. Disregarding the doubtful arrangement and size of the valve ports and gas passages in this motor one remains confronted with its top heaviness and extraordinary height. Expansion rings on the valve, a good point in itself, is not worked out well in detail because single wide rings are used and each ring, which should be stationary, is located opposite the oil conduct leading to the valve. Rotating rings cannot be used properly. This motor can be well classified as an experimental attempt and would need much refinement to become a marketable product.

A similar line of reasoning can be carried out in regard to another class of motors, namely, those employing other

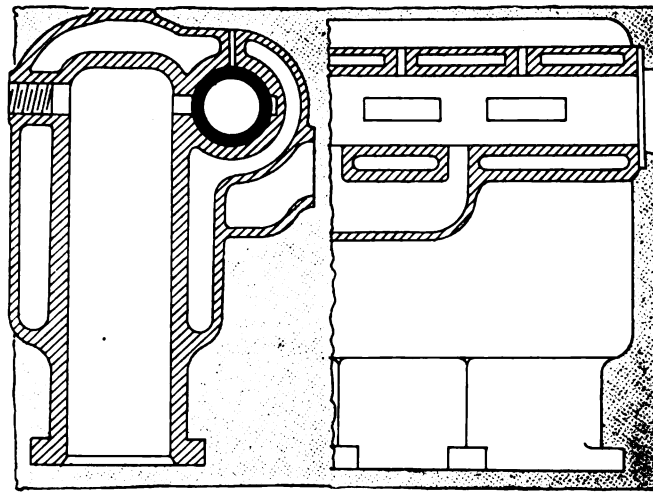

Fig. 6—Sectional views of Von Bottweiler motor, showing rotary-valve arranged alongside of cylinders

means for intense valve cooling, chiefly air or intake gases. The Henriod-Darracq of the latest design belongs to this class, using the intake gases for internal valve cooling. This would indicate that, notwithstanding their method of shielding the valve, some trouble must have been experienced in keeping it at low temperature.

The Walker motor, Fig. 7, also belongs to this class, because apparently it draws the intake gases through the inside of the valve from one of its ends. This method in itself can be approved, but the manner in which the exhaust gases are dealt with by this motor could easily offset the benefit from internal valve cooling by the intake gases. Not only is the inside inlet gas-carrying section of the valve restricted by the exhaust channels, but they also add materially to the heat-absorbing surface of the valve. Their irregular direction would make valve distortion very probable. The feature of balancing the pressure on the valve may appear satisfactory on paper, but practice demonstrates that heat is the greatest enemy and it is therefore preferable to let the valve resist pressure rather than to double its heat-exposed surface. By leading the gases under pressure to the opposite, or cylinder port valve side, additional places are created where the gases have to be prevented from spreading alongside the valve surface in addition to reducing the exterior water-cooled surface in contact with the valve.

(To be continued)

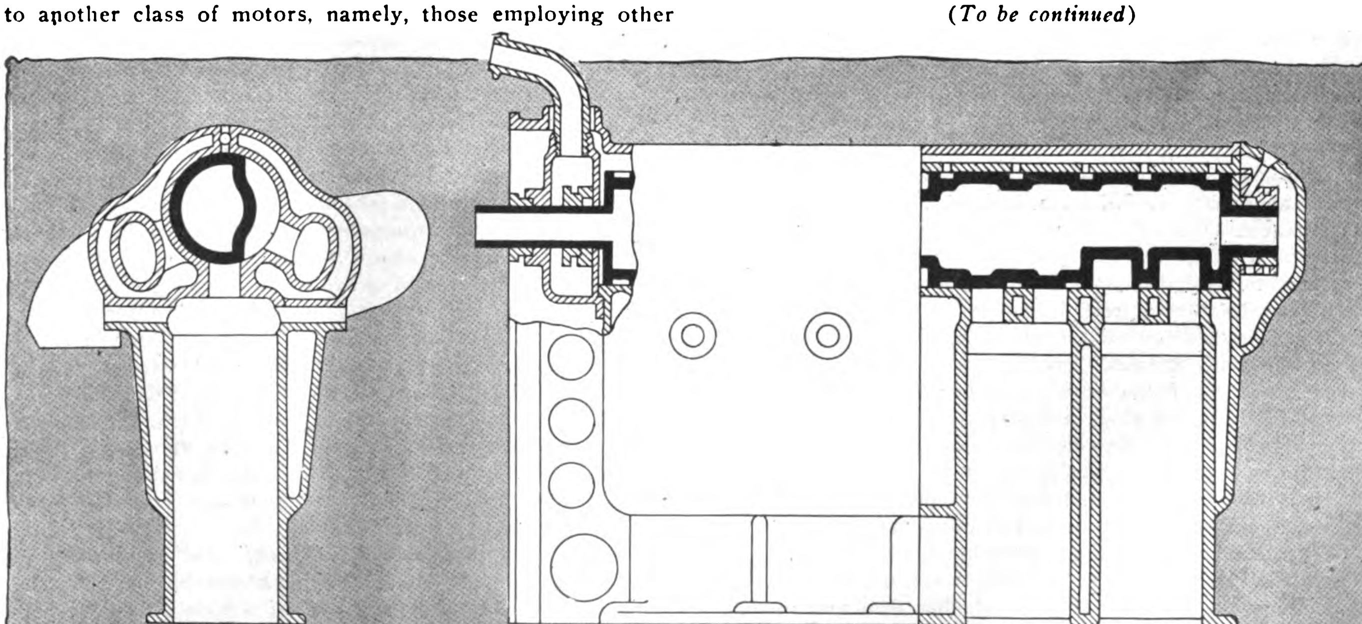

Fig. 7—Walker rotary-valve motor in which the intake gases are drawn through the valve for cooling

Engineers Discuss Slide-Valve Motor

New Swiss Engine Employs Long Slide Valves of Crescent Section with a Travel of Over 1 Inch

Fischer Valveless Type Subject of a Paper Presented Before Detroit Section of the S.A.E. by L. B. Brown

ONE of the most interesting features of the regular monthly meeting of the Detroit section of the Society of Automobile Engineers, held in that city last week, was a paper on the new Swiss Fischer sectional slide-valve engine recently brought to this country by L. B. Brown and George Radcliffe, London, Eng., and which since its arrival in this country has been subjected to a comprehensive dynamometer test at the Hudson plant, Detroit, under the direction of Howard Coffin, chief engineer. The promotion of this motor in America, as reported in THE AUTOMOBILE for December 12, has been undertaken by the Motor & Gear Improvement Company.

This motor has as a substitute for poppet valves two slide valves V disposed oppositely in the cylinder walls, Fig. 1. These slide valves are crescent-shaped in cross-section and operate in crescent-shaped recesses V1 in the opposite sides of the cylinder bore, which, by the way, is not a circle, but an irregular figure composed of approximately two nearly semi-circular parts connected by two crescent-shaped parts. These slide valves occupy each approximately 69 degrees of the cylinder wall circumference. They are of cast iron, and extend the entire length of the cylinder, and approximately 2 inches below it. At their lower extremities they carry slots for the engagement of the operating mechanism consisting of box cams, the shafts of which are driven by Coventry silent chains from the crankshaft, thus insuring positive reciprocation in both directions and entirely dispensing with the use of springs, thus giving silent action.

These slide valves have a travel of 1 inch and carry in their upper ends a single port or opening P in each, the port at one side being for intake gases and that at the other side for exhaust. Each port has .7 square inch area.

The reciprocation of the sleeves is such as to give the following timing:

Inlet opens 11 degrees after upper dead center.
Inlet closes 71 degrees after lower dead center.
Exhaust opens 63 degrees before lower dead center
Exhaust closes 19.75 degrees after upper dead center.

The timing is thus not standard as the intake and exhaust overlap approximately 8 degrees, which is claimed to give additional power. With this timing and with a peculiar box-cam construction of the actuating mechanisms there is obtained a characteristic long dwell after the closing of the ports, so that the slide valves are at rest during the compression and power strokes. The dwell on compression is 149 degrees. The exhaust is opened for 262 degrees.

The motor is a four-cylinder monobloc type, with a bore and stroke of 3 5-16 and 4 3-4 inches; to be more exact, 85 by 120 millimeters. It has thermosyphon cooling, splash and force-feed lubrication, and high-tension ignition. To this extent the motor is entirely conventional. The special features which make it interesting as compared with other motors are its valve mechanism and its small clearance volume.

The clearance is about 18 per cent. of the total cylinder volume, giving a compression which is higher than that in use in general practice. It would seem that this high compression would cause spontaneous combustion, and while the makers have certain reasons of their own to account for the fact that this does not take place, it is hoped that tests on this point will either confirm their reasoning or evolve some other. It is relevant to state that during the several months in which the engine has been under observation there has been no instance of spontaneous ignition or of overheating.

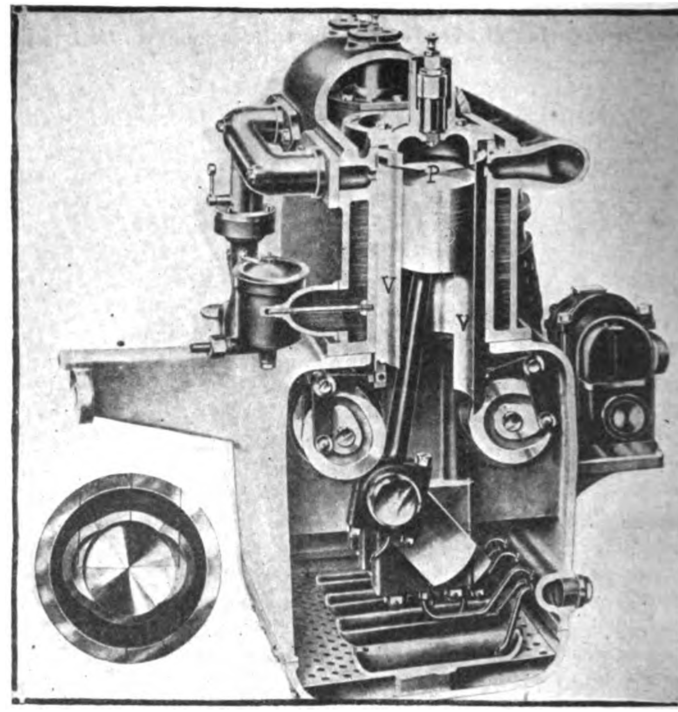

Fig. 1—Sectional view of the Fischer vertical slide-valve engine discussed at a recent meeting of the Detroit section of the S. A. E.

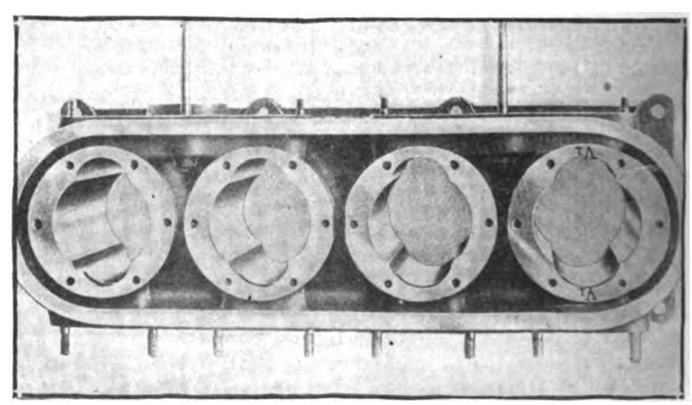

Fig. 2—Showing the top of the casting of the Swiss slide-valve motor with the recesses in which the valves operate

The cylinders have semi-spherical shaped heads with cylindrical extensions passing through the waterjacket into which the spark-plugs are fitted. This construction places the spark-plugs in the ideal position and provides convenient means for attaching the waterjacket cover. The cylinder heads are removable, having the conventional flange construction for bolting to the cylinders. In addition to the cylindrical extensions to accommodate the spark plugs, which are on top of the heads, there are also extensions which project downward into the cylinders, these acting as bull-rings or guides for the valve slides, being intended to hold the latter on their seats. Cored passages connect the cylinder ports to the flanged openings to which the inlet and exhaust manifolds are attached.

"In early experience with this engine," said Mr. Brown, "we were at a loss to account for its high power, having in mind its small dimensions, and a great deal of speculation on this point failed to evolve any tangible explanation until the engine was brought here to Detroit, where dynamometer tests and a more

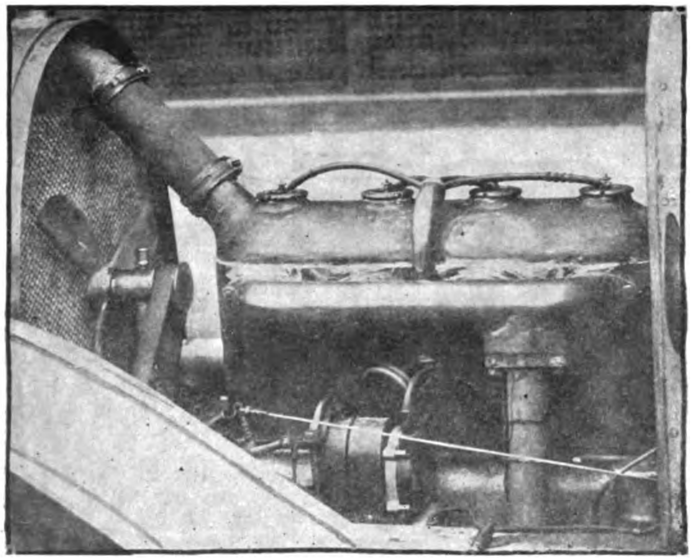

Fig. 3—Exhaust side of the Fischer vertical slide-valve motor showing the position of the magneto

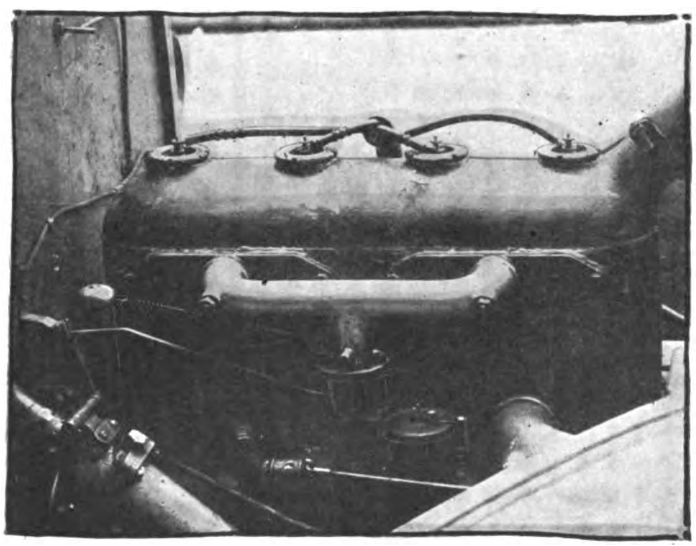

Fig. 4—Intake side of the Swiss slide-valve engine with mounting of carbureter and T-shaped manifold

thorough examination disclosed certain facts which indicate that in addition to the structural difference existing between this engine and the more conventional types there are differences in the thermal conditions which make the motor unique. It is doubtless to these features that the relatively high power must be attributed. The small clearance is one factor.

"Another feature which must have a marked effect on the thermal efficiency is the small surface exposed to the combustion temperature. It will be noticed that with the exception of the bull-ring every bit of metal is in close proximity to the cooling water.

"Reference to the brake horsepower curve shows that the power increases steadily up to 2,000 revolutions per minute, and that it is in direct proportion to the speed up to 1,500 revolutions per minute. You are familiar with the characteristics of brake horsepower curves of poppet-valve types, and will perhaps be interested in comparing these with the curve of the Fischer engine. Comparison with the curve indicating mean effective pressure, Fig. 5, will also be interesting and you will note that the peak in the curve shown is reached at 1,400 revolutions per minute and that it is in excess of 105 pounds throughout the entire range of speed."

Mr. Radcliffe, who collaborated with Mr. Brown in the preparation of the paper and who has had more to do with the

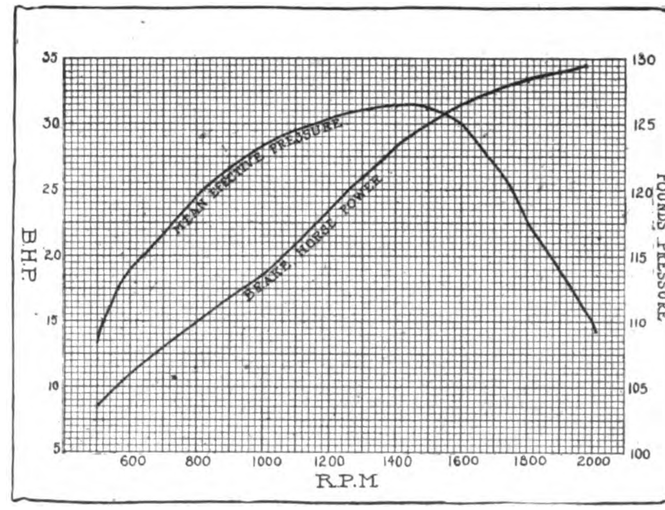

Fig. 5—Diagram showing results of tests made at the factory of the Hudson Motor Car Company, Detroit, Mich., on the new Swiss slide-valve motor

operation of this engine than anyone else in this country, answered the many questions which were brought up in the discussion. What are the reasons for lack of pre-ignition? The reasons are the perfectly-shaped combustion chamber of the motor, efficient cooling and the peculiar timing.

E. R. Fried, in the discussion before the society, brought up the question of cylinder-wall expansion, stating that in his opinion it would be uneven, due to the fact that the wall is exposed to the cooling for about 220 degrees, while the rest of the circumference is covered by the valves. Mr. Fried further stated that the sleeves also would not expand evenly. To refute these statements, Mr. Radcliffe cited the examination of the cylinders when the engine was recently taken down at the laboratory. The micrometer tests showed that the cylinders were out of true round only a negligible amount. The motor has a gasoline consumption of 20 miles to the gallon in a car with a total weight of 4,300 pounds. The oil consumption is 1 pint to 160 miles.

Electric Furnace for Brass Work

Various forms of electric furnaces are making their appearance upon the market and this serves to stimulate the desire to harness the electric current to the brass foundry.

Investigations, calculations and results of experiments have demonstrated one thing and that is in the matter of cost. To compete with oil melting at the present time, electric current will have to be obtained at a cost less than it can be made except, perhaps, by means of an internal combustion engine or by water power. It has been stated that current will have to be obtained at a price of from 0.40 to 0.80 cent per kilowatt hour in order to compete. This price is very much less than power can be purchased from any city power plant, or can be made by the ordinary method of generating with a generator and steam engine.

The cost of the current, therefore, is such as to preclude the use of the electric current for melting in competition with coal, coke or oil. The field for it, however, is in the manufacture of special alloys or work that cannot be done in the ordinary way. It is probable that the near future will see the electric furnace extensively used in melting metals, but upon special work, as it cannot compete in cost with ordinary methods of melting as practised at the present time.—*Brass World*, November.

There is no formula for finding the radiator cooling surface necessary for any four-cylinder motor that is applicable to all types and makes of motors or radiators. This is because of the great variation in the cooling efficiency of the various designs of motors and radiators made. Each radiator maker, however, will be able to very closely approximate the amount of surface of its own design most suitable for any particular motor.

Gear Ratio for Speed Roadster—Dealers in Honolulu—Packard Clutch Adjustment—Overhauling Hudson Roadster—Removing Carbon Deposit—Lighting with Dry Battery—Misfires on Grade—Rayfield Carbureter Adjustment

Constructing Speed Roadster

EDITOR THE AUTOMOBILE:—I am rebuilding a 1910 model Jackson 30 into a speed roadster. It has a Northway high-speed motor and a three-speed and reverse Brown-Lipe gearset. I wish to use a four-speed gearset and am wondering if the following ratios would give satisfaction with my motor. You will notice that the following table is the same as Table No. 2 given in THE AUTOMOBILE of November 28, with the exception of third and fourth speed:

	Speed	Tran.	ratios	Ratios engine to wheels
Direct drive	4	....	1	2
Direct drive	3	....	1	4
Direct drive	2	2.1	1	7.35
Direct drive	1	3.76	1	13.16
Direct drive	R	4.57	1	15.99

Where can I get such a transmission and about what would it cost?

How can I get into the racing game? I wish to drive in some of the large races next year, including the 500-mile at Indianapolis, the Grand Prize and Vanderbilt. I am unable financially to enter and drive my own car and the only encouraging reply I have had from factories was from the National Motor Vehicle Company. They stated that if they went into the racing game again this season they would write to me. Are there not men who have cars entered in the larger races and who hire drivers? If so, can you refer me to any of them? The only trouble in this game seems to be in getting started, and if I go into it I wanted to start in the right way.

Hilton, N. Y. B. W.

—The table you give would seem to be satisfactory for a car of the type you mention. Such a gearset may be procured from any of the gear manufacturers who make a specialty of gears for automobiles. The cost would depend on the material and whether the concern had to make the gears specially for you or if they had them on hand. If they had to make them special the cost would be tremendous. THE AUTOMOBILE is in receipt of many inquiries from persons who would like to become racing drivers. It is solely a matter of securing the sanction of the American Automobile Association's contest board, and then of convincing some one that you are the man to pilot his car to victory. We have no record of any one who desires to enter his car in any of the races and who is in search of a driver. The majority of successful drivers are those who either attract attention while engaged as factory testers or who gain prominence in amateur events.

Honolulu Has Score of Dealers

Editor THE AUTOMOBILE:—In the issue of THE AUTOMOBILE for November 7 you accredit Hawaii one dealer. There are at least a score. Honolulu has more than 1,000 registered automobiles and over 300 cycles, with a few trucks and $5,000 cars in livery service here are common. Fine roads on all islands of group. Many tourists bring cars. They can motor to brink of volcano.

Honolulu, Hawaii EDWARD TOWSE.

Adjustment of Packard Clutch

Editor THE AUTOMOBILE:—Kindly advise me how to adjust 1907 Packard clutch. I have had it relined and oiled up but it does not seem to take hold at all and I have to lay the car up because I can't run it.

New York City. J. HEITZMAN.

—The clutch used in this car was one of the most delicate clutches manufactured. It is very susceptible to the slightest amount of oil on the surface of the leather. The tension on the clutch spring is very light, owing to the reduction gear used in its application and a very light pressure on the pedal is required to disengage it. A method which has been used with success in adjusting this clutch is to press down the pedal and hold it there while the link at the traveling nut which operates on the screw passing through the small gear is disconnected. The small gear is then turned over one tooth on the large gear. Now connect the linkage again, and the clutch will give a stronger engagement. One user of a 1907 Packard has removed the leather and replaced it with asbestos fabric. He claims much greater satisfaction can be obtained with this arrangement than with the leather, as it is not so susceptible to oil and can be slipped indefinitely without glazing. As the clutch on this car is very apt to become soaked with oil thrown up from the flywheel and drip pan, this arrangement should be very satisfactory.

Tuning Up a Hudson 20

Editor THE AUTOMOBILE:—I am overhauling my Hudson 20 model 1910, and would thank you to give me some information through Letters Answered and Discussed.

1. How can one remove a valve cap that sticks and is obstinate? I am grinding in my valves and find that No. 7 valve cap cannot be removed, although I have tapped it while exerting pressure upon it, heated up the motor and placed ice in the cap, etc., but without avail.

2. The levers that control the spark and gas mounted above the steering wheel have a tendency to stick together so that when one advances the spark the gas lever goes with it and *vice versa*. I have oiled, tried to adjust, etc., but only after working them back and forth several times can they be used independently.

3. Lately the Stromberg carbureter has been working strangely. After the motor has stood all night, and when endeavoring to start in the morning, and I might state the maximum temperature during the night is about 48, it is necessary to prime through the cocks twice or three times before the motor will work at all, then if the throttle is opened the least bit wide there is a mighty cough and the engine stops, then more priming, etc., until it gets heated up, then it will work very satisfactorily.

4. In grinding valves would you advise the use of the breast drill? It would facilitate the work greatly and I can see no reason why its use would impair the work, although I have been told it was better to use the screw driver. Some good in-

struction along the lines of valve grinding, adjusting, timing, etc., I know would be appreciated by your readers.

Oregon City, Ore. W. R. Logus.

—1. The method employed in the Hudson service department in New York, and which they state will remove the most stubborn valve cap, is to drive in a piece of hexagonal stock in the manner shown in the diagram, Fig. 1. The stock can be secured of a size that will just fit the opening. A wrench can then be put on the hex and if necessary a pipe can be slipped over the wrench for extra leverage. In this way you will surely be able to move the cap.

2. If you will bend the levers apart at the lower end of the steering column the chances are that they will not work together. In case the rods within the hollow steering column are rusted together, a little kerosene poured down the steering column will loosen them.

3. The difficulties are with the weather rather than your carbureter. As long as the carbureter works well after the motor becomes warmed up, a proceeding that takes but a few minutes, you are not in a bad position. Many motorists have trouble in starting in cold weather and as a general rule it may be stated it is necessary to adjust the carbureter for a rich mixture after the winter sets in. The fuel is harder to vaporize on account of the cold weather and deficiency in vaporizing powers must be made up by the increased amount of fuel. This fact has been clearly brought out in Robert Brewer's articles on carbureters now appearing in The Automobile. In case the cold weather has necessitated a change of adjustment of your carbureter in order to meet the climatic conditions of winter, a few words on the adjustments of the Stromberg may be in place. The carbureter, model B type, is illustrated in Fig. 2. Turn the low speed adjusting nut up or down until the spring controlled by same seats the valve lightly. See that the high speed spring has plenty of play and is free. Start the motor and turn the low speed adjustment nut up or down until the motor turns over smoothly at low speed. Advance the spark and open the throttle until the motor speeds up considerably. If the motor then backfires through the carbureter, turn the high speed adjusting nut up until backfiring ceases. If the mixture is too rich turn the nut down. In order to avoid too rich a mixture it is best to turn the nut down until backfiring occurs and then turn it slightly up so that it will just run at high speed without backfiring. The high speed spring should have at least 1-32 inch play when the motor is at rest.

You should not have any trouble starting with this carbureter if you close the shutter in the fixed air intake.

4. The breast drill is perfectly satisfactory for valve grinding if you do not try to do the work in too much of a hurry by exerting too much pressure on the valve which you are grinding. The reason that the screw driver is preferred by many is because it is easier to give a light pressure and to gauge the force with which the grinding is being done. A brace, such as that shown in Fig. 3, is better than a breast drill and also quite fast. When using a breast drill do not put any weight on the work as the weight of the drill is sufficient. Turn about three of four times one way and then back again, lifting the drill after every second or third reverse. If you use emery dust and oil you should be particularly careful not to have the emery too coarse. The finest procurable emery dust should be secured because the chances are strongly in favor of your grooving the valve seat if coarse emery is used. Many valve-grinding compounds are excellent and give as good service as can be secured from the regular oil and emery mixture.

Suggests Rather Expensive Plan

Editor The Automobile:—I believe you are wrong in your answer to Transmission in the November 28 issue, page 1126. I have also the same trouble; new gears are only a little better. A good clutch can be made out of the transmission by taking out the gears and putting in fiber and metal disks, then put a sliding gear transmission just back of the present location of the ball joint universal, then couple the driveshaft to the back of the new housing and support it with a cross-member. It would, of course, be necessary to lengthen the frame to do this. Another way is to replace the entire rear axle with a new transmission rear axle of unit construction. I am thinking of doing this this winter and would like to know the address of parts makers who would supply suitable parts for this machine. These machines drive fine on high gear, but the planetary gearset is a noisy power-consuming contraption that should never have been put in an automobile.

Any information or advice your readers can give me on this subject would be appreciated.

Battle Creek, Mich. Albert B. Metcalf.

Mixed Fuel as Carbon Remover

Editor The Automobile:—What effect would 1 gallon of kerosene have when mixed with 5 gallons of gasoline on a gas engine? Would it be good as a carbon remover and would it injure the engine in any way?

Schenectady, N. Y. Herbert M. Stark.

—So far as The Automobile has any record the effects of the mixture of kerosene and gasoline on carbon deposit has never been recorded. It has been suggested to use a double carbureter which would take pure gasoline for starting and use the mixed fuel after the motor has become warm. The trouble of mixing fuel every time it was necessary to put in a new supply has deterred many from making the experiment, although it has been said that satisfaction was obtained from the mixture so far as the power developed was concerned. The vapor of kerosene is one of the best carbon removers and solvents that we have, and since this is the case it seems as if the occasional use of the mixed fuel would result in cleansing the cylinder. It is doubtful, however, that the advantages gained would repay the necessity of making radical alterations in carbureter adjustment and in fact of the design of the carbureter itself. Kerosene injected into the cylinder while it is hot would be vaporized, and would act in the same manner as the method you suggest.

Dry Batteries for Lighting

Editor The Automobile:—How many hours will five No. 6 Columbia igniter dry batteries run (and make a good light) on a 2-candlepower burner, the batteries testing 26 to 30?

Iuka, Kan. M. & P.

—The New York representative of the National Carbon Company, which makes these batteries, states that he will get about 30 hours' service with a 6-volt, 2-candlepower lamp on five Colum-

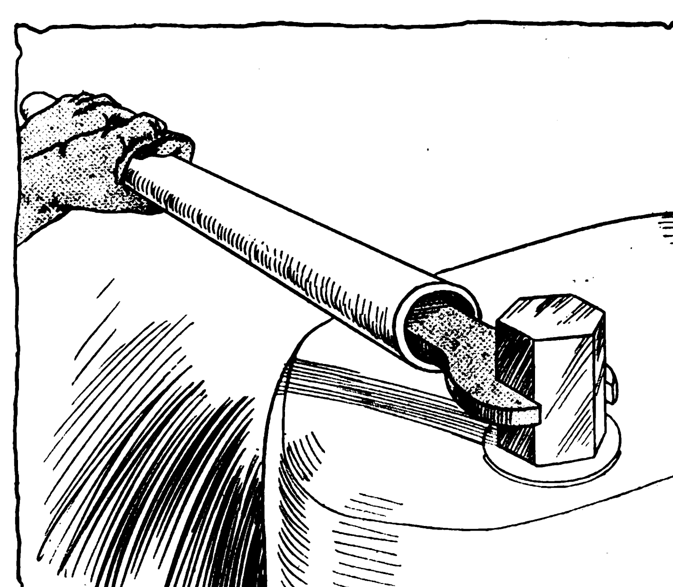

Fig. 1—Removing troublesome valve cap on Hudson 20 Roadster

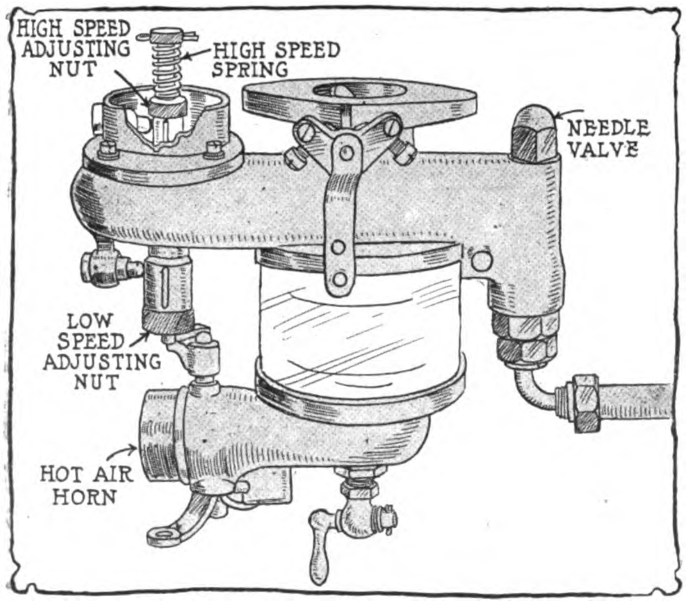

Fig. 2—Stromberg carbureter, showing adjustment points

bia cells. This is merely an estimate, however, as you will probably be able to get a longer time if the battery is not constantly at work, but has a period in which to recuperate. If you would use a multiple-series set of fifteen batteries, three series of five, the time would be increased to a considerable degree. In fact, the makers of the battery claim that a service of 250 hours could be expected on one burner.

Misfires When Climbing Grade

Editor The Automobile:—I have on my hands a Chalmers 36 which is giving me trouble and I would like to have a little of your advice. My car while on level fires all four cylinders, but on a hill fires only on three, although all plugs and carbureter are apparently in good condition. Car has run only 800 miles since last grinding. Kindly advise me as to what remedy to use.

New York City. F. Erber.

—About the only thing that could cause the trouble you mention is a spark plug whose gap is too wide. The distance between the points should be 1-64 inch. When it is much greater than this, the high-tension current generated at high motor speeds will be sufficient to cause a spark to cross the electrodes, but when the motor speed falls off no spark occurs. It must be remembered that the resistance to a spark is much greater under the conditions which exist in the cylinder than in the open air at atmospheric pressure. If you will close up the gaps of the plugs until they are 1-64 inch in width the trouble will no doubt disappear.

Adjusting the Rayfield Carbureter

Editor The Automobile:—Being a subscriber to your journal, I would appreciate it very much if you would explain the proper way to adjust a Rayfield carbureter. I am using one of these carbureters on a Ford model T and I do not think I have the adjustment quite correct.

Lindsay, Ont., Can. Madison Williams.

—A view of the Rayfield carbureter is given in Fig. 4. The various points which have to do with its operation and adjustment are lettered in the illustration. Start your motor and throttle it down as far as it will possibly go and still run steadily, hitting on all four cylinders. After the motor has been running at this speed for a period of 3 or 4 minutes indicating that it would not be choked up and stopped after a short time turn the low speed adjustment out or in other words the fuel adjustment nut to the left until the screw leaves contact with the cam. When this condition has been reached the needle valve is just seated. Now turn the fuel adjustment nut to the right for a distance of one and one-quarter turns. Now try the motor again. If it does not run steadily turn the fuel adjustment screw to the right, thereby increasing the fuel supply, until it does run evenly. It must be remembered, however, that it is an advantage to run with this screw to the left as far as possible as this cuts down the flow of gasoline and hence makes running more economical. When the least throttle opening at which the motor will run steadily is found the stopscrew which prevents the throttle from closing any further should be turned up as far as it will go. When you have succeeded in getting the motor to run evenly at low speed open the throttle and advance the spark, allowing the motor to run at high speed. Should backfiring occur, the high speed adjustment screw should be turned to the right until it ceases. It would be a good idea to turn this screw to the left until the motor starts to backfire or power seems to show a marked decrease, at which point it should be turned back until the motor runs properly. Turning to the right increases flow of fuel and to the left decreases it; therefore, it should be made an object to run the motor with the high speed adjustment screw as far to the left as possible. When you have made what you think to be the proper fuel adjustments on high and low speeds, open the throttle slowly. Should backfiring occur between the low and high speeds turn the automatic air adjustment to the left. This increases the tension on the automatic air valve spring and maintains a slightly richer mixture at the intermediate and high speed. As a general rule it may be remembered that backfiring to the carbureter is due to too little fuel and therefore either the high-speed or low-speed adjustment nuts should be turned to the right, depending upon whether the motor is turning over at higher or lower speed and if it runs steadily with the throttle closed. First, be sure that the motor idles properly before trying adjustments at high speed.

A simple test to determine if the mixture of any speed is too rich is to press with the finger the auxiliary air, giving surplus air. If the motor speeds up it shows that as it stands it is too rich, and the automatic air adjustment should be turned to the right until the motor begins to reduce speed or starts to

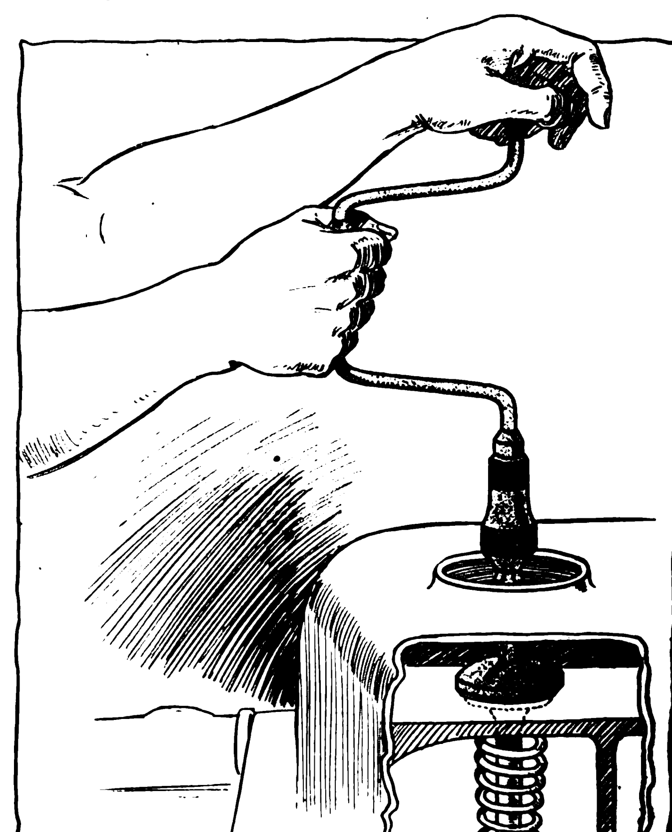

Fig. 3—Using brace and bit for grinding in valve

backfire: it should then be turned to the left until the motor runs smoothly. This should be done with the throttle about one-eighth open. If you follow these instructions carefully, the Rayfield carbureter should give you the best of satisfaction on your car, provided that you are using the correct size.

Silencing Noisy Magneto Gears

Editor THE AUTOMOBILE:—For the benefit of your readers who may be having the same trouble, I wish to give my experience with the Hupmobile 20 runabout:

After having been run about 2,000 miles my engine developed a slight knock which gradually grew more noticeable. After taking off the cylinders and removing what little carbon there was, and taking up the connecting-rod bearings I found the knocking a little worse if anything, the magneto having been returned as near as possible to its former position on the bracket.

I next tried placing the magneto so as to mesh the gears a little deeper and the knocking disappeared immediately and engine runs as quietly as when received from the factory.

Magneto can be shifted by simply loosening the bolts which hold it without taking them out, thereby avoiding the difficulty of getting the correct teeth in mesh, should magneto be removed far enough to let the teeth slip out of position.

Kensington, O. E. W. DIBBLE.

Some Questions of Motor Design

Editor THE AUTOMOBILE:—How is the lubrication of the rotary valve in the Darracq motor effected? Is this valve not very similar to the Duryea rotary valve brought out a few years ago, except that it is located further down upon the cylinder wall, below the compression space, instead of even with it?

2. What advantage has the new 1, 3, 4, 2 timing over the old 1, 2, 4, 3 timing?

3. What compression is commonly used in Knight sleeve-valve motors?

4. Does not the flywheel in front construction used by some makers have the same effect in damping vibrations as the vibration damper used upon Daimler and other motors? Does the radiator have to be made larger if located between the motor and dash, and how much? How many square inches of radiating surface per square inch of flame-swept cylinder wall is considered good practice?

5. What was the trouble with the pin-gear drive? I believe a transmission of this nature was brought out a few years ago by a Mr. Belden and used in a machine driven by an air-cooled motor which took part in a Vanderbilt elimination race, and worked all right, although the motor did not. Such a drive would have some advantage, principally that of being able to get several different speed ratios and all direct, with only two moving parts.

6. Does not the carrying of the gasoline tank in an exposed position as on some roadsters and touring cars result in a loss by evaporation, much more than from a tank covered up or under the seat?

Mentone, Cal. JOHN LEFLER.

—1. Lubrication in the Darracq motor is accomplished by a force-feed pump which delivers a stream of oil through the space between the sleeve and its housing. The film of oil between the sleeve and the part containing it is depended upon to maintain the gastightness of the passage. This motor is of a different principle than the Duryea motor, except that in both cases a rotating sleeve is depended upon for gas distribution.

2. It has been found easier to balance and to manufacture crankshafts having the two central cranks on the same side of the turning axle. This is especially the case in the three-bearing crankshaft where the condition of having the two front pistons down and the rear pistons up at the same time would have tremendous influence towards causing unbalanced stresses.

3. Compression averages between 60 and 70 pounds.

4. THE AUTOMOBILE has no record of any test to determine the

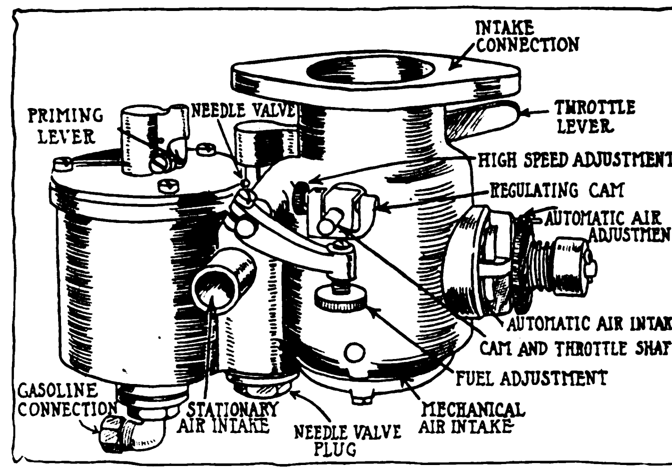

Fig. 4—Various adjustment points on Rayfield carbureter

effect of front flywheels as vibration dampers and sees no reason why they should have that effect. The size of a radiator naturally depends upon the area exposed to cooling influences. When covered over, the air which strikes the radiator is warmer than when the radiator is at the front of the car, and hence, in order to secure the same cooling capacity, its area must be correspondingly larger. Your question regarding radiator surface could not be answered in definite figures, as there is no specific ratio between radiating surface and cylinder wall area that is considered good practice. This depends on the type of radiator, size of the waterjacket, capacity of the pump, thickness of the cylinder and numerous other questions of design.

5. The pin gear is still on the market, although it has not met so far with much success. The difficulties are said to be in keeping the pins tight and also to back up the thrust on the plate holding the pins.

6. A tank which is heated by a strong sun in the summertime or by the exhaust pipe at any time is more apt to sustain loss by evaporation than one which is tight. This is due to the volatile nature of the fuel.

Size of Peugeot Racer

Editor THE AUTOMOBILE:—In one issue of THE AUTOMOBILE in which was a description of the Peugeot car you stated that it had a bore of 4.3 inches and a stroke of 7.8 inches, giving a piston displacement of 453.087 cubic inches.

In another issue you say the bore and stroke are 100 millimeters by 200 millimeters which is, of course, different from the above in that it equals a bore of 3.947 inches and a stroke of 7.874 inches.

Then, from another article I learn that the piston displacement is 470 cubic inches. This being entirely different from either of the above. Now would you kindly tell me which one is correct? Are the valves inclined 45 degrees to the vertical or 45 degrees to each other?

Also would like to know the compression pressure piston clearance gear ratio on high, and the meaning of B. N. D. chrome nickel steel.

In a recent article you stated that the National Motor Vehicle Company, Indianapolis, Ind., makes its own rear axles. As far as I know, the American Axle Company makes these parts on the series V cars.

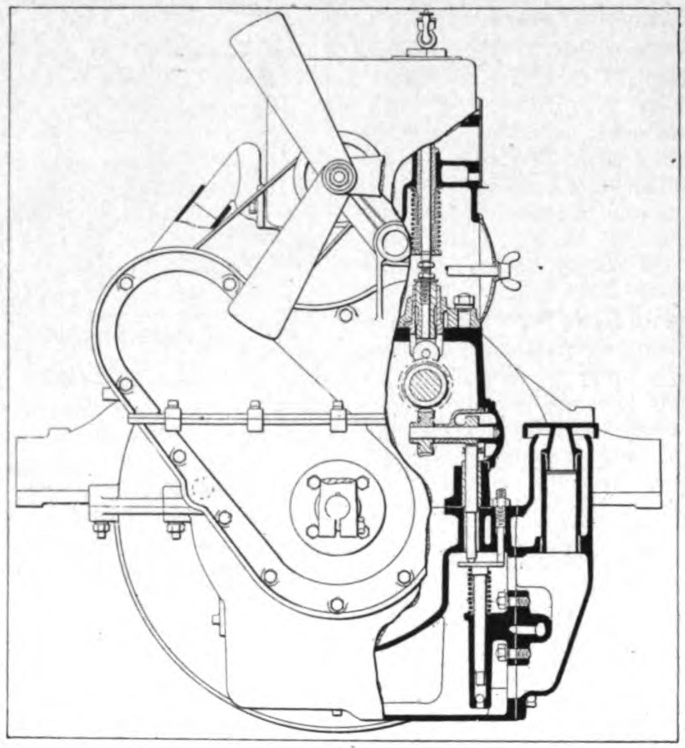
New York City, N. Y. F. HOLLIS WELLS.

—The bore of the Peugeot racer is 4.3 inches and the stroke 7.8 inches, giving a piston displacement of 453 inches. The valves are inclined 45 degrees to the vertical. The B. N. D. chrome nickel steel is steel made by a process used in the Derihon Works of France and Germany. It is a brand name for steel made by this process.

The National Motor Vehicle Company has its pressed steel work done outside. The machining, however, is done at the National factory.

Oakland Adds a Six—Continues Three Fours

FOR 1912-13, which may very aptly be called the season for sixes, the Oakland Motor Car Company, Pontiac, Mich., has fallen into line and has added a six-cylinder chassis to its most attractive line of cars. Oaklands for the coming year are all distinctive in body design, whether they be fours or sixes, and they reflect credit upon their designers. In addition to the six, there are three four-cylinder types, known as models 35, 40 and 42, the first of which has a 3.5 by 5-inch motor, while the other two are equipped with a power plant having a cylinder bore of 4.125 inches and a stroke of 4.75 inches. These cylinder dimensions also apply to the 6-60, as the new six is designated.



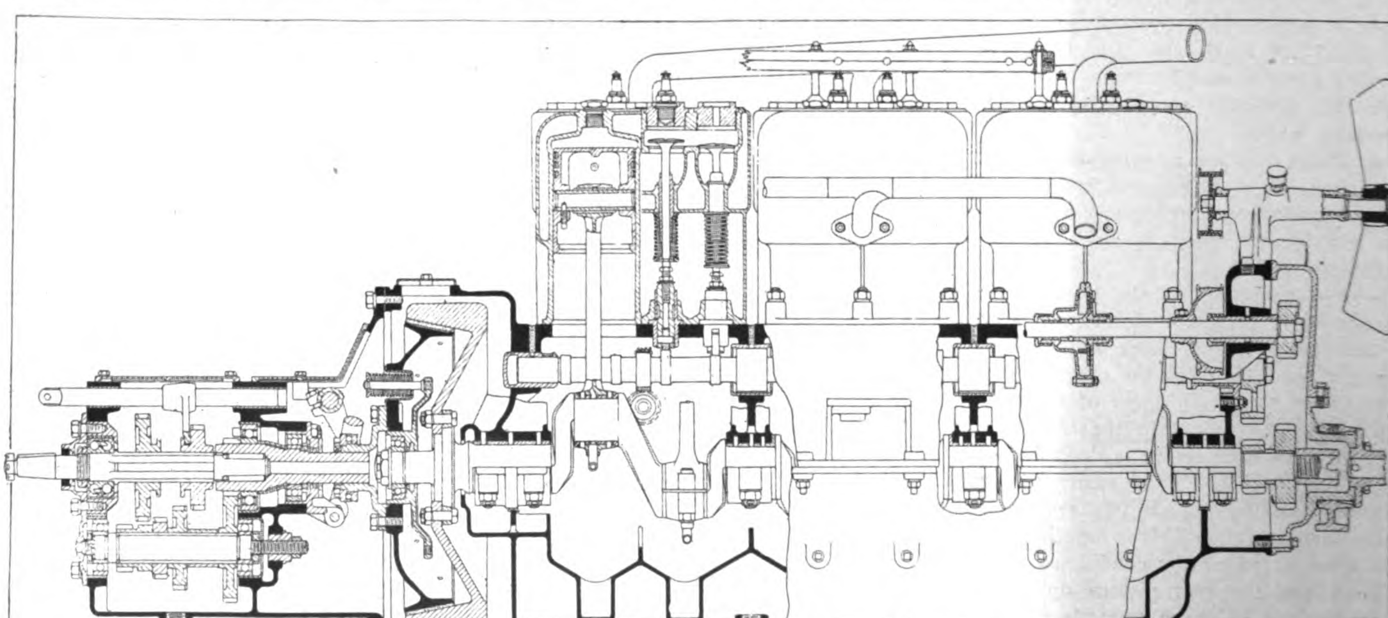
Part sectional front view of the Oakland 6-60 motor, showing inclosed valves and inclosed silent chain drive of magneto and pump

In all models, the same general constructional features are incorporated, although minor differences are to be noted. By having one general design, it is possible to standardize a great many parts, and the Oakland concern has not lost sight of this growing tendency in automobile manufacture.

The last-named two models, namely the model 42 and the 6-60, are practically alike in all constructional details, although not all of their respective parts are of the same dimensions. All features of the two motors are alike, the only difference being that the six motor has its magneto, water pump and camshaft driven by silent Coventry chains, whereas these parts of the four-cylinder motor, which is of the same bore and stroke, are driven by gears. The motor of the model 40 is identical with that of the 42, while the smaller engine of model 35 carries out all the design details of the others on a smaller scale.

Models 35 and 40 differ from the other two in that the rear axles are semi-floating instead of floating; they have a single-drop frame in place of a double-drop construction; their radiators are flat and not V-shaped; they carry 15-gallon gasoline tanks under the front seats and feed the fuel to their motors by gravity, whereas the other models have force-feed and have their gasoline tanks slung under the rear of the frames; and their wheelbases are, of course, less. The two higher-priced models are also provided with Deaco combination lighting and ignition systems, while model 35 is equipped with Remy ignition and storage battery electric lighting and model 40 carries a Briggs magneto and acetylene gas lamps. In all other respects they are the same as the 6-60 and the 42.

Having mentioned wherein the two smaller Oaklands differ from the two just named, it will perhaps be less confusing to the reader if the description of the line is confined to the 6-60 and to the model 42. The six has a rated horsepower of 40.9 and the model 42, 27.25, according to the S. A. E. formula, but these figures are much below the actual power output, each cylinder being able to deliver a little over 10 horsepower under average



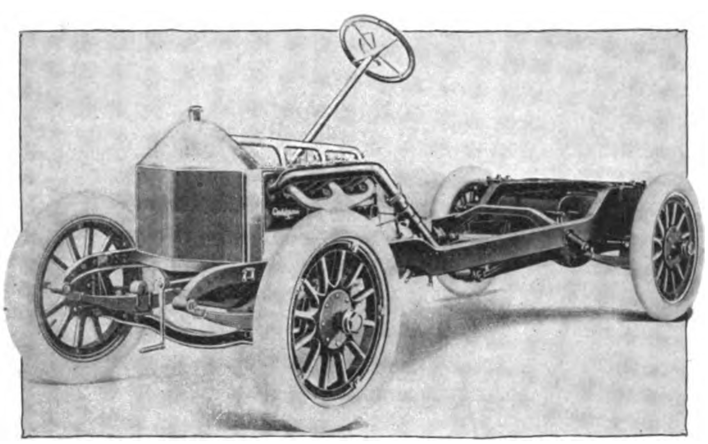
Unit power plant of the 1913 six-cylinder Oakland, including section through transmission and part sectional view of motor running conditions. The long stroke of 4.75 inches has a bearing on this.

The various dimensions of these two motors, which are representative of the Oakland line, are given:

	Four-cylinder	Six-cylinder
Bore	4.125 in.	4.125 in.
Stroke	4.75 in.	4.75 in.
Number crankshaft bearings	Three	Four
Front crankshaft bearing	1.125 by 3.5 in.	1.25 by 3.5 in.
Center crankshaft bearings	2 by 2.5 in.	2 by 2.5 in. (two)
Rear crankshaft bearing	2.25 by 4 in.	2.25 by 4 in.
Front camshaft bearing	1.25 by 2.5 in.	1.25 by 2.5 in.
Center camshaft bearings	2.25 by 1.5 in.	2.25 by 1.5 in. (two)
Rear camshaft bearing	1.25 by 2 in.	1.25 by 2 in.
Length of connecting rods	11 in.	11 in.
Connecting rod bearings	2.125 by 2.25 in.	2.125 by 2.25 in.
Wrist pin bearings	1 by 2.25 in.	1 by 2.25 in.
Piston length	5.25 in.	5.25 in.
Valve diameter	1.75 in.	1.75 in.
Valve lift	.34375 in.	.34375 in.
Diameter magneto and pump shaft	.4375 in.	.4375 in.

It will be seen from the above table that the two motors are practically the same in all details, and this may also be extended to apply to the chassis. Although of shorter wheelbase, that of model 42 is identical in all details of importance with that of the six. There is only one exception to this: model 42 has a gear ratio of 4 to 1, which is the same as that of the other three fours, while the six has a ratio of 3.5 to 1. And so, model 42 may now be eliminated from the description, and this is justifiable, since the new 6-60 is typical of Oakland practice.

In keeping with previous Oakland design, the six motor is in combination with a unit power plant, the gearbox being bolted directly to the flywheel housing. The cylinders are of L-head type, in pairs. Water-jackets are integral; valves are all on the left side and the valve-stems and springs are inclosed by cover plates. These features are conventional, and, in general, it may be said that there is nothing unusual about any of the Oakland power plants. They are in accord with present-day American practice. Connecting-rods are H-section drop forgings, the wrist-pin bearings being bushed with bronze. Each wrist-pin is fixed to one of the piston bosses by a set screw. At the crank ends, the connecting rods are provided with die-cast, babbitt metal bearings, while shims are used for adjustment. The pistons have flat heads and they are provided with three rings each, above the bosses. The crankshaft is forged, the flywheel web being integral with the rest of the shaft. The flywheel has a diameter of 16 inches. Four main bearings support the crankshaft, these bearings fastening to the upper half of the crankcase, permitting of the easy removal of the lower half.



Three-quarter view of 6-60 chassis, showing double drop frame

Valves are of conventional design, and are provided with double hex-nut adjustments, while the lifters are of the roller type, operating in guides located in the upper half of the crankcase.

One feature of the six motor which marks a step forward in motor design is the use of silent chains for the driving of the magneto, pump and camshaft, as already mentioned.

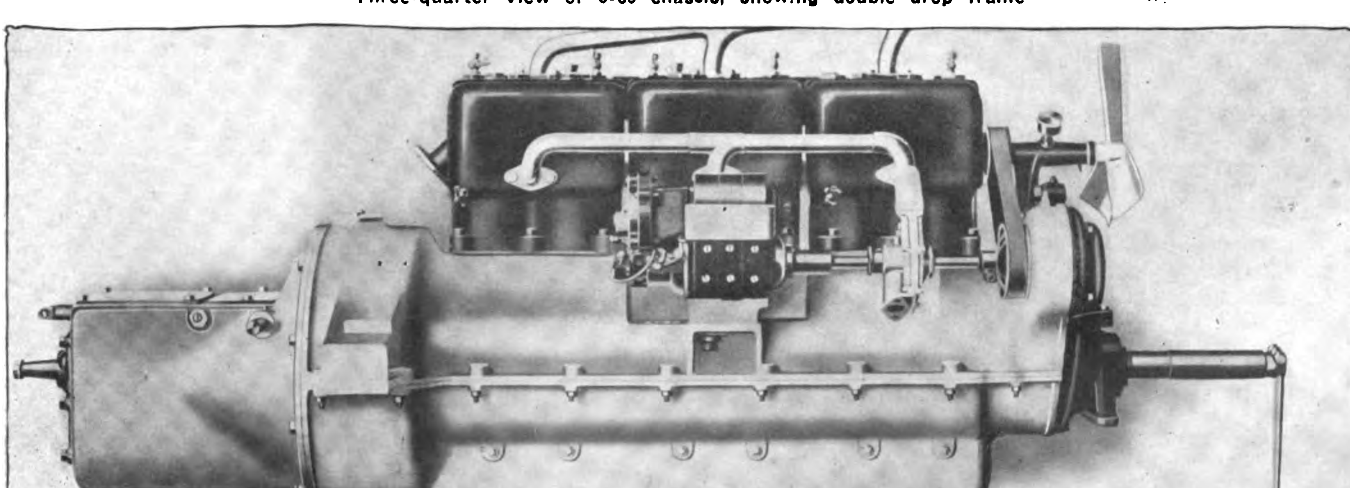
As is usually found with unit power plant construction, the motor and gearset are suspended at three points, the front support being on a cross frame member and in the form of a trunnion which is an integral part of the gearcase. The two rear supports are provided through the use of arms, cast as a part of the upper half of the crankcase and fly-wheel housing.

For ignition the Deaco system is used, and the generator, which, in addition to furnishing current for ignition, provides for the lights, is located about half way forward on the right side of the motor. It is held on a crankcase bracket and driven by a flexible coupling from the pump shaft. The generator furnishes current primarily for ignition purposes and the surplus is transferred to a storage battery from which it is carried to the various lights. Both ignition and lighting are within control of the driver.

Splash lubrication is used in the motor, and circulation is kept up in the usual way by a plunger pump, cam operated from the camshaft through gears. Below each connecting rod there is an oil trough into which the end of the rod dips, splashing the oil to the bearings and into the cylinders. The lubricant eventually runs into a sump in the lower center part of the crankcase from which point it is returned to the oil troughs and to the chains at the front of the motor by the oil pump.

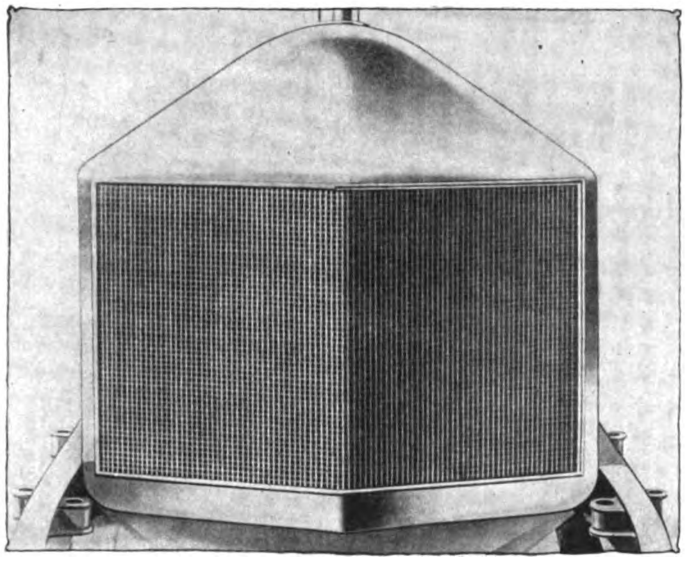
Positive water circulation is provided in the accepted way by means of a centrifugal water pump located forward of the magneto and driven by silent chain. The cooling fan, which is a three-blade propeller type, is driven by a belt from a pulley on the pump shaft. The radiator is one of the distinctive features of Oaklands for this season, in that it is V-shaped and is fitted with a German silver top, also V-shaped. The radiator is of the square-tube type.

On the new six, a 1.5-inch Stromberg carbureter is pro-



Showing the clean design of the right side of the Oakland six unit power plant. All valves are on the left side, inclosed vided, whereas, on the four-cylinder model of similar construction a Schebler, Model O, is used. The gasoline tank, which has a capacity of 21 gallons, is located at the rear of the car under the frame and hence pressure feed of the fuel is required. The tank is provided with a gauge which gives the gasoline level at any time.

The drive and control are on the right, the gears being shifted by a lever within the car. Service brake, clutch pedal and other control apparatus is standard. Steering is through a worm-and-nut gear. There is a drag link which is provided with ball joints and shock-absorbing springs. This link has a diameter of .875 inch, while the cross connection back of the axle is 1 inch in diameter. The front axle, which is of standard I-beam type, carries integral lugs which act as steering stops.



V-shaped radiator used on Oakland six and model 42

Passing to the drive and chassis construction, it will be seen that the propeller shaft is not inclosed, the drive being taken care of through substantial rear springs and through a torque arm running parallel to the propeller shaft from a cross member of the frame at the gear-box to the rear axle housing. The front end of the torque arm is provided with a spring buffer. Two universal joints are used in connection with the drive shaft, one of these at the gearbox and the other at the rear axle.

The rear axle is of the floating type, which means that the entire load is carried by the housing and none of it by the rear axle shafts.

The front springs are half elliptic, 2.25 inches wide and 41 inches long. The rear three-quarter elliptic springs, which are mounted outside of the frame, have the same width, but they are 53.75 inches in length. Great flexibility and easy riding qualities are claimed for these springs by the maker. A new feature of the spring suspension is that the rear springs are underslung; that is, they are suspended from the axle tubes rather than resting on plates on top of the axle housing, as in ordinary construction. All the spring clips are constructed of .62.5-inch material.

As to the frame, this is provided with a double drop; that is, it is lowered just to back of the power plant and raised again at the rear so that it will clear the rear axle. By so constructing the frame a low center of gravity and reduction of side sway to a minimum are claimed. The low drop construction makes possible the elimination of side aprons, spring pockets, step hangers, running boards and so on, as inspection of the body views will bring out.

Oakland bodies are exceedingly attractive, and, in addition to the V-shaped radiator feature, that of replacing the running boards with four aluminum steps, one for access to each door of the car, is an innovation. Bodies of any type may be had. Upholstery is very heavy. The designers have looked carefully into the comfort of passengers, and roominess in all models has been striven for. Ventilators have been put in the sides of the hoods of some of the models. All the bodies are flush-sided, with door handles and hinges concealed. The low angle to the cowl dash on all Oakland body designs lends a finishing touch. In the roadsters, the seat is made wide enough to accommodate three.

All models are provided with demountable rims The trimmings are of nickel, a feature which is now looked upon as standard by most American motor car designers. Electric headlights, side lights and tail lamp, Klaxon horn, complete toolkit, tire repair outfit, pump and jack are standard equipment on the six and its four-cylinder counterpart, Model 42. On Model 40 the lamp equipment consists of acetylene gas headlights and oil side and tail lights, in addition to robe rail, horn, gas tank and full tool outfit. Model 35 has an electric lighting system and carries other accessories similar to those of model 40

Recovery of Scrap Zinc

A method of recovering zinc from galvanized iron scrap has been patented by Eduard Broemme, of St. Petersburgh, Russia and Rudolf Steinau, of Nuremberg, Germany. The process is:

The scrap is boiled in a solution of sodium bisulphate and common salt (equal parts of each are used) until the zinc has gone into solution. It is stated that a very pure solution of chloride of zinc is obtained that contains sodium sulphate, sodium chloride and only traces of iron and manganese.

This solution, it is stated in the patent, can be used for the manufacture of lithophone, a material used in the making of rubber goods, and which is a compound barium and zinc sulphide.—*Brass World*, November

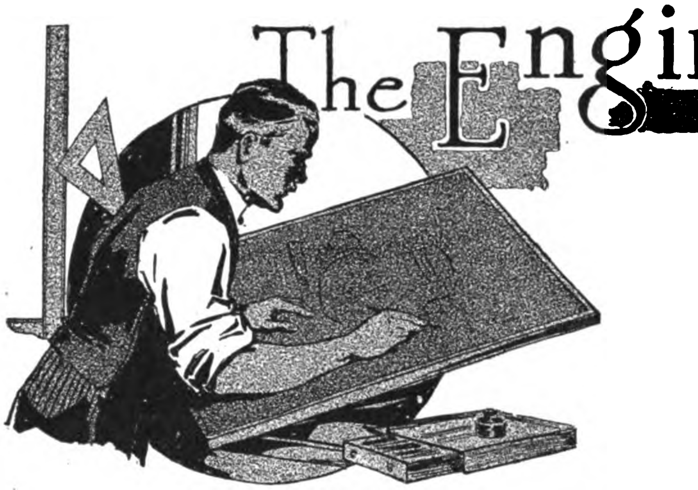
The Engineers' Forum



3-Point vs. 4-Point

Respective Merits of These Systems as Means for Supporting the Motor and Gearbox

Schimpff Believes in Four-Point Suspension for Motor and Three-Point for Gearbox

Part IV

A. Schimpff Thinks Three-Point Practicable

J. Demmler Considers Four-Point as Standard

CINCINNATI, O.—Editor THE AUTOMOBILE:—We have found on our pleasure car that a four-point suspended four-cylinder engine with legs made heavy enough to withstand any strains due to twists in frame from road inequalities is the proper thing, as our subframe takes twists at points past these legs.

Our transmission is three-point suspended, set amidship with universal joint between it and the motor. We have yet to receive the first complaint of any trouble caused from this construction.

The proper construction of trucks seems to be the vital question. On our trucks we have had the same suspension of motor and transmission as on the pleasure car, and in very few instances we have had one of the rear legs on the engine crack or break off. This we attributed to the stiffness of the subframe and the subframe anchorage over the strength of the leg.

We have been testing several trucks lately arranged with three-quarter platform rear springs, thus making the frame three-point suspended, using 40 inches diameter wheels, giving easy riding on account of missing all small ruts in the roads.

Three-point suspended transmission, four-point suspended motor with the two front legs flexibly connected to the subframe, allowing the engine legs at this point to move in a vertical position when the frame is distorted. These two fasteners are arranged with a coil spring of suitable tension to prevent the motor from vibrating when the truck is in a normal position.

This construction is proving satisfactory in our estimation, after being given the most severe tests on the worst roads we could find.

We are having one of our motors arranged for a third-point suspension in the front and will test this out in combination with all the features of this test now going on with the four-point suspension motor.

As we have yet to try this three-point suspended motor and it being our first, we, of course, are not in a position to speak for it from practical experience. However, we believe it is going to help matters a great deal, especially with larger wheels, three-quarter platform springs, and our special features enumerated above.—A. SCHIMPFF, Engineering Department, Schacht Motor Car Company.

GROVE CITY, PA.—Editor THE AUTOMOBILE:—In comparing three-point with four-point suspension from an engineering standpoint, and, in theory, I prefer the former to the latter.

Considering the matter from a practical standpoint experience is teaching us that all the advancements made in industry are built on compromise between theory and practice. We make many sacrifices in theory in order to make a design practical and commercial. We condemn our gear-shifting device in theory. In practice we use it, because we don't know of anything better that would satisfy the formulas of theory and also be possible for practical use.

In a four-cylinder motor are unbalanced forces and momentums which are the cause of vibrations and thus having the motor bolted to the frame rigid can only be of advantage to the motor.

I have been connected with leading companies in Germany and France and all of them have used four-point suspension for some time and still use it today, and their troubles with breaking crankcases on account of four-point suspension have been very few.

Using something more flexible than iron blocks between the motor arms and the side members gives good results.—J. DEMMLER, Bessemer Motor Truck Company.

PARIS, FRANCE.—Editor THE AUTOMOBILE:—True three-point suspension is used on the 175-horsepower Peugeots, acknowledged the fastest European cars of the 1912 season. The entire power plant, motor, clutch and gearset, is carried on an elongated U subframe. There is so little transverse rigidity in the subframe that it would be possible to make the two ends meet without any great effort. The necessary rigidity, however, is given by the motor base and the gearbox. When disassembling, the entire plant with its subframe is taken out of the chassis; the different organs are put together on the subframe, and the rigid block thus formed is fitted into the frame. It is this entire block which is three-point suspended, there being a central trunnion attachment to a very substantial double transverse frame member at the front, and ball and socket attachments at each end of the frame, all three attachments being provided with lubricators. The entire power plant is so completely isolated from the twisting strains imparted to the frame members that it has not been found necessary to place a universal joint between motor and gearbox.

W. F. BRADLEY

DETROIT, MICH.—Three-point suspension, in my opinion, misses its point when the transverse member is not so arranged as to furnish a rigid connection to the side-frame, at the same time giving a flexible connection to the rear suspension point of the motor. With too rigid a connection the three-point suspension can in reality become a virtual four-point, and I would state that for this reason flexibility is important.—T. B. MORLEY.

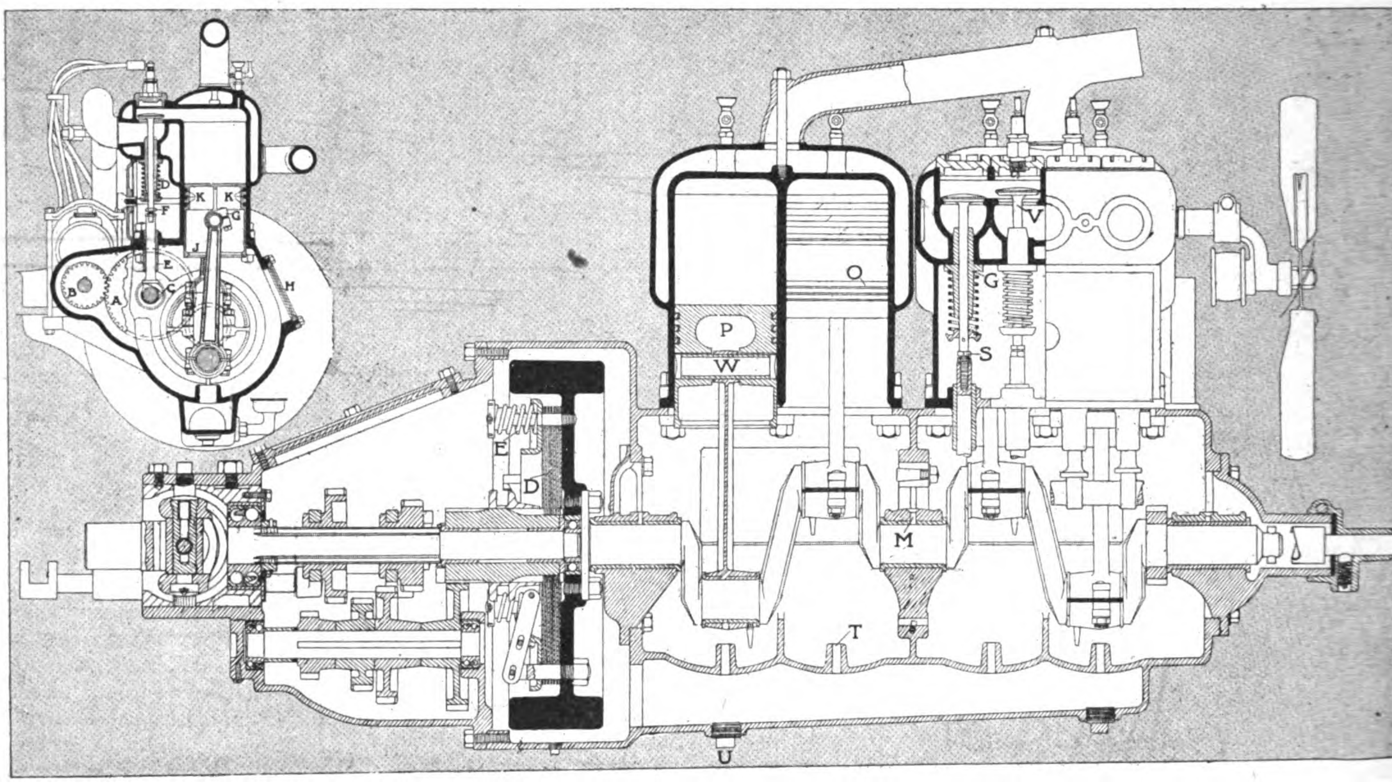


Fig. 1—Sectional views of the motor, clutch and gearset showing the distinguishing features of design common to all models

Marathon Drops One Model; Continues Three

Increased Wheel Base and Added Body Comforts Feature 1913 Line, Change in Nomenclature of Models

MARATHON racing has been used as a basis in naming the new Marathon cars. The three models which will be on the market for 1913 will be known as the Runner, Winner and Champion. One model has been dropped, while the three just mentioned will be continuations of the cars put on the market for the previous season with refinements. These refinements have not been very radical, the same general features of design being continued with one exception, this being the enlargement of the motor in the Runner model. The model which was dropped was that known as the L-30, while the former models which corresponded with the Runner, Winner and Champion were the K-20, M-40 and N-50 respectively.

In making the alterations necessary in improving the new cars and bringing them up to date many details have been taken up. Among the more important are included an increased bore and stroke in the Runner, floating rear axle construction in the two larger chassis, with semi-floating rear axle in the small one. In all models, however, the rear axles are incased in a one-piece steel housing. The wheelbases have been increased in the Runner and Champion models, in the former from the 90 and 96 inches used in the roadster and touring chassis, respectively, this year to 104 inches for 1913; in the Champion model the wheelbase is 123 inches instead of 120 inches in the 1912 design. The Winner model has a 116-inch wheelbase, the same as the model L-30 of the season just closing. Tires are the same in size except in the case of the smallest model, where they have been increased from 32 by 3 inches to 32 by 3 1-2 inches. The springs have been lengthened in all three models to increase the easy riding qualities of the car. The most general changes have occurred in the body designs rather than in the chassis. For 1913 the bodies have been widened considerably and also have been given more leg room in the front of the car. On the roadster body the length has been increased 8 inches.

Uniform design throughout the line is particularly noticeable in the power plants, in which there is little difference except as to dimensions.

The design embraces in each case a unit power plant with a four-cylinder motor of which the cylinders are cast in pairs, a multiple disk clutch operating in oil in the flywheel housing and a sliding gearset with straight line drive to the rear axle through a single universal joint. Among the other features common to all the models are a dual system of ignition comprising a magneto and storage battery, a front axle of I-beam section with ball bearings and a worm-and-gear type of steering mechanism with four full positions to take up wear.

Some of the engine details which are present in all three sizes are the L-type of cylinder head, the valves V are on the right side and driven by spiral timing gears B, A; interchangeable exhaust and inlet valves; push rods E, of the mushroom type, offset to allow for even wear and provided with means of easy adjustment; thermo-syphon circulation of the cooling water with a belt-driven fan; and a crankcase cast in one piece to obviate the chance of leaking joints and to provide a rigid support for the crankshaft. In the two larger models the valves are inclosed on aluminum plate for each pair of cylinders and which is quickly removable. The camshaft is a single forging, the cams G being forged on the shaft and then hardened and ground. The crankshaft M is offset and is a drop forging of nickel steel, as are the connecting-rods. The bearings are of special nickel babbitt and are supported from underneath in the one-piece crankcase. This permits adjustment of the bearings from the top. Lubrication is obtained through a flywheel circulating system with a constant level and splash to the cylinder. The flywheel housing is in the lowest place in the crankcase reservoir and here the oil is picked up by the rotation of the flywheel and carried by centrifugal force to a pocket near the top of the flywheel housing, from which it is distributed by gravity to the motor bearings. Cooling is on the thermo-syphon principle with a vertical tube radiator. The magneto is fastened to a lug cast on the crankcase and is driven through a special gear and Oldham coupling.

Within the flywheel is located the clutch. This consists of twelve saw steel plates running in oil. As it is supported on two bearings, the plates are always in alignment and the possibility of grabbing is minimized. It is claimed that the leverage in the clutch pedal is great enough to allow it to be disengaged by one finger. Three springs are used in the clutch and an easy means of adjustment is provided through a handhole on the gearset housing. This type of clutch has been a feature of Marathon construction for the past 7 years.

Arranged in the housing bolted to the flywheel housing are the transmission gears of the gearset. Final drive is through a shaft inclosed in a torsion tube, and a single universal joint inclosed in a ball on the end of the gearset case. Radius rods from the rear system to the end of the torsion tube are added. Channel section frames of pressed steel are employed and springs are semi-elliptic in front and elliptic in the rear. Rear axles are of Hess construction.

With the foregoing details of general design in view a discussion of the individual models becomes simplified. The smallest model, the Runner, has cylinders of 3 1-2 inches bore and 4 1-2 inches stroke. This is quite an increase in size over the corresponding model of last year whose cylinders were 3 1-4 inches by 3 1-2 inches bore and stroke. The gearset of this model provides two forward speeds, although, like the others, it is of the sliding type. The rear axle in this model is semi-floating. Both roadster and five-passenger touring bodies are fitted to this chassis. The roadster body has a gasoline tank of unique shape. This shape is called the cam and the reason for the name is apparent from the illustration. The shape is such that every drop of fuel in the tank will be drained from it no matter in what position the car may be standing.

The Marathon Winner chassis carries three bodies, a roadster, touring and coupé. Its motor is rated by the makers at 35 horsepower, the cylinder dimensions being 4 1-4 inches by 4 1-2 inches bore and stroke. The Champion model has a motor of 4 1-2 inches by 5 1-8 inches bore and stroke and is supplied with roadster and five or seven-passenger touring bodies.

Aside from the usual equipment of top, top boots, windshield, speedometer, tire iron, demountable rims, and so on, there is supplied as regular equipment special seat covers, a rather unusual offering in the list of regular equipment.

Harking Back a Decade

FROM *The Automobile and Motor Review*, Dec. 20, 1902: Special apparel for motoring began to make its appearance as soon as cars became capable of making 20 miles an hour. For the male automobilist the clothing was strictly utilitarian but the eternal feminine demanded that something beside warmth, protection and service should enter into the new styles. As a result of this demand some chic and at the same time useful costumes have been evolved for miladi. So far as the men are concerned, nothing in the clothing line has been developed that will not show transmission grease on the front and yellow mud behind.

The lawmakers of Buffalo now propose to frame an ordinance levying a special tax on all vehicles using the city streets. Automobile owners have filed a protest based upon the fact that as their machines are equipped with rubber tires they do the streets no damage and consequently should not be taxed.

Thieves in Pittsburgh entered the barn of William Williamson and stole the motor from his automobile. They displayed no ingenuity in loosening the motor as they apparently used a crowbar to break the supports.

Saks & Company, of New York, have established complete motorization of the delivery system employed by the store. The battery consists of eight light delivery wagons and two 1-ton trucks all made by the Vehicle Equipment Company.

Frederick A. Halsey recently has republished the articles written by him several years ago for the *American Machinist* on the efficiency of the worm gear. Mr. Halsey maintains that 90 per cent. efficiency can be obtained by this transmission.

The secretary of the Automobile Club of Great Britain and Ireland is now making an inspection of various Irish courses to select a route for the next Gordon Bennett Cup race. A 64-mile circuit has been tentatively decided upon but a protest is expected from the French automobile authorities.

The present French automobile show is pronounced to be the greatest in automobile history. President Loubet opened the show on December 10. The new type honeycomb radiator of Mercedes pattern; the Panhard reproduction of the electro-gasoline system wherein the current is generated for driving purposes by a gasoline engine; an eight-cylinder C. G. V. motor that does away with transmission gearing and numerous other improvements in construction are the main features of the show. A host of Americans have been in attendance at every session.

Alexander Winton has declined to receive the challenge of Barney Oldfield for a match race. Mr. Winton does not race for money and Oldfield's challenge contemplated a purse and side wager.

Rules for the Gordon Bennett race have been promulgated by the Automobile Club of America. The rules provide for a deposit of $600 by each entrant; if the entrant is not selected to start by the committee, the deposit shall be returned. Besides Alexander Winton, H. S. Harkness, of Brooklyn, L. P. Mooers and W. T. White, of Cleveland, and Percy Owen, of New York, have signified their intention of entering. The rules about the deposit money are supplementary regulations of the A. C. A. The actual rules of the contest are provided for under the deed of gift and the ideas of the club holding the race.

The Houck Automobile Company of England has placed an order for $250,000 worth of automobiles to be made by the International Company of Toledo.

French Cars for 1913

ALTHOUGH the French manufacturer feels somewhat humiliated in that the recent Paris Salon has been eclipsed by the annual exhibition across the channel, he, nevertheless, has the satisfaction of knowing that so far as the development of the modern automobile is concerned he is still keeping well to the fore. In fact, the engineering departments of the French factories are as busy to-day as they were 6 or 8 years ago.

To America belongs some of the credit of this activity; the French engineer has at last realized that he wasted time in the development of the single-cylinder motor, which was at best a monstrosity, and while satisfactory for racing and high-speed country work was not successful for touring and city use. The development of the small-powered four-cylinder car in America and the reduction in price, together with the aggression of American exporters, have led to this exceptional French activity.

In their aim to develop small cars the French engineers have not forgotten the good engineering and careful constructions of the high-powered car, neither have they aimed at a cheap car which is being sold on its accessory equipment. They have set boldly to work to develop a high-class, efficient, low-powered car, one whose initial cost is not so low but whose upkeep figures will be relatively low, because of good materials, careful workmanship and light weight. The engineering effort expended on these models is as great as that on the larger cars.

The French verdict on motor design is an unmistakable one; long-stroke motors are used everywhere. In fact, there is scarcely a square motor listed for next year. One-half of the entire list of manufacturers show stroke-bore ratio of 1.5 to 1, and there is a goodly number with a stroke-bore ratio of 2 to 1, this number including several of the most conservative makers. This increase in stroke has been brought about because of necessary fuel consumption and also the horsepower tax.

The non-poppet valve has made little progress, excepting in that the sleeve type has gained a great many French adherents. The apparent reason why many of the non-poppet designs of a year ago are missing to-day is that they have failed to stand up under strenuous tests.

Two tendencies of French construction for next year are very apparent, one being the adoption of worm drive, and the other the demountable wire, steel, or wood wheel. Originally France was stoutly opposed to both of these measures because they were looked upon as English developments. The leading manufacturers have been experimenting carefully with both for 2 years, and now not a few of them list the demountable wire wheel as stock, with the demountable wood wheel or steel wheel as optional. The same is true of worm drive. Several concerns list this as stock with a bevel option. One of the biggest French houses in designing its worm-driven axle has mounted the worm above the axle, a difficult design, if a low-body support is to be had. This difficulty has been surmounted by a longitudinal ridge in the car floor to accommodate the propeller shaft, a construction similar to that used with some American underslung constructions. All French concerns do not use the overhead worm, but mount it underneath and mount both motor and gearbox at a slight angle to give straight-line drive.

Silent-chain drive in the motor for camshaft, magneto shaft, water pump, and in some cases oil pump, has become almost universal. The chain manufacturers in Europe have been particularly aggressive in the development of a satisfactory chain to meet these exacting conditions, so that the adoption of the chain has not been retarded in the slightest by the lack of a satisfactory product. The difficulty of mounting the sprocket through proper centers to meet chain requirements has been speedily overcome by the co-operation of the chain engineer and the car designer.

There is a wealth of minor improvement in many of the French machines. The spring suspension is unsettled. Some, who have used three-quarter elliptic gears have reverted to the semi-elliptic. Shock-absorbers are more general. Universal joints have been improved and radius and torque rod constructions have been improved upon. The double-drop frame has come in for more general consideration. Lastly, one of the best business manufacturers has adopted the American idea of selling a completely equipped car, which, if it takes hold, can be readily seized upon by the American exporter and the movement will work more or less of a revolution in the French selling field, as well as one which will aid in the exportation of American cars to South America, Australia, etc., where they are in competition with French products, and where the European product has largely dictated the selling situation.

Detroit to Produce 385,150 Cars for 1913

Total Output of the City's Automobile Factories for 1912 Was 192,695 Machines—95.4 Per Cent. of 1913 Production To Be Pleasure Cars—Commercial Vehicle Output to Increase 198.6 Per Cent. for This Season—Thirty-Six Companies Now Manufacturing

DETROIT, MICH., Dec. 15—More automobiles will be built in the city of Detroit alone during 1913 than were manufactured in the entire country in 1912. Carefully compiled statistics show that the combined production of all classes of vehicles will be close to double that of last year in this, the hub of the industry. In thus estimating their market and laying their plans for the greatest year in their history, the manufacturers have apparently given little thought to the coming change of politics, being more interested, as was expressed at the recent banquet of the National Association of Automobile Manufacturers in Detroit, in the problems connected with supplying the demands of the trade than they are in the change in the political situation.

Following is the comparative production of Detroit cars of all classes for 1912 and for 1913:

	1912	1913
Gasoline pleasure cars	185,560	367,450
Gasoline commercials	4,310	12,875
Electric pleasure cars	2,315	3,675
Electric commercials	510	1,150
	192,695	385,150

These figures show that the contemplated production for the coming year is 100.5 per cent. greater than that of 1912, or about double.

Pleasure Car the Main Issue

The compilation further brings out the city's pre-eminence as a pleasure car center, the production of this type of vehicle greatly overshadowing that of commercial vehicles. Of course, one big factor in this great pleasure car showing is the tremendous production of one factory—the Ford plant—which will endeavor to turn out 200,000 complete machines, all of the pleasure car type. Even the making of light delivery cars is to be stopped, concentration on the one class even more deeply than heretofore being the future program.

Analysis of the totals shows that 95.4 per cent. of Detroit's output for 1913 will be of the gasoline pleasure car class, 3.35 per cent. of the gasoline commercial, 0.96 per cent. of the electric pleasure and 0.29 per cent. of the electric commercial.

The percentage increases over 1912 are surprising when viewed in cold figures, as follows:

Gasoline commercial car increase over 1912	198.6 per cent.
Electric commercial car increase over 1912	125.0 per cent.
Gasoline pleasure car increase over 1912	98.3 per cent.
Electric pleasure car increase over 1912	96.6 per cent.

Thus, although producing far less commercials than pleasure cars, Detroit's commercial vehicle output has increased proportionately faster than has its pleasure car output. This is further evidence of the fact that while business vehicle manufacture is about 10 years behind that of the passenger car it is growing by leaps and bounds and will need only a few years to assume the proportions which it should have.

Another interesting feature of Detroit's factory statistics is the proportion of the country's entire car manufacture for the coming year that is centered here. The following table will serve to bring out forcibly the marvelous growth of the Michigan city as the greatest automobile center of the world, the figures previous to 1912 having been obtained from the Detroit Board of Commerce statistics:

Annual production of cars—total of all classes	
1905	10,736
1906	(Estimated)
1907	(Estimated)
1908	18,200
1909	45,000
1910	114,120
1911	135,000
1912	192,250
1913	385,150

The state census report for 1904 shows that in that year there were twelve concerns actively engaged in the manufacture of automobiles in Detroit, while a year later this had swelled to twenty-two. Last year (1911) there were about thirty, while at present thirty-six companies are actively manufacturing.

There is considerable speculation as to what will become of the great number of machines which will be produced. Some with pessimistic views have said that there will be over-production, but such great increase has not been decided upon without deep consideration of this point, and there seems to be an opinion among the makers that there will be difficulty in supplying the demand even now. Yet the makers do not depend solely upon their American trade to buy all their product. The increasing foreign market is to take care of a large share of the cars. Although imports of automobiles have fallen off greatly, government export figures show that exports have nearly doubled their volume of a year ago. The following table showing the export automobile business from Detroit to Canada and England is given by the government export figures:

1903	$82,933
1904	162,529
1905	255,597
1906	269,554
1907	422,101
1908	399,010
1909	699,706
1910	2,106,615
1911	3,864,994
First 2 months of 1912	1,296,873

At this rate the 1912 foreign shipments of automobiles from Detroit will be approximately $7,780,000 and should reach $15,000,000 in 1913.

New York Has More Cars than France

PARIS, Dec. 12—France possesses 76,771 private automobiles that number having paid taxes during the year 1912. The figures show an increase in the number of cars during the year to the extent of 12,562. These figures are generally accepted as an estimate of the number of cars in use in France, but they are, in reality, of a very conservative nature.

The official figures for the last 6 years are as follows:

1907	31286	1910	53669
1908	37586	1911	42609
1909	44769	1912	76771

The total falls far below the number of automobiles registered in New York State at the present time, and, for that matter, considerably below the number in California. New York had 102,870 cars on October 1, while California had 83,728.

Philadelphia Club Opens New Clubhouse

Powell Evans, President of Club, Officiated and Made Dedication Address at Laying of Cornerstone

Open House Was Order of Day and All Afternoon Members and Friends Inspected Building

PHILADELPHIA, PA., Dec. 14—With ceremonies appropriate to the occasion, the formal opening of the new club house and garage of the Automobile Club of Philadelphia on Twenty-third street between Market and Chestnut streets took place today. At the same time the announcement was made that the proposition submitted to members to lease the mammoth building to the Philadelphia Automobile Trade Association from January 15 to February 5 for the purpose of holding the annual automobile show there, had been approved. The show will extend over two weeks, from January 18 to February 1.

Powell Evans, president of the Automobile Club of Philadelphia, officiated today and made the dedication address at the laying of the cornerstone in the Ludlow street corner of the structure. Mr. Evans in a brief talk reviewed the object and aims of the organization and what it hopes to accomplish, with the co-operation of the members, in the working out of legislative problems of interest to the motorist and public alike and in the development of good roads. Open house was the order of the day, and all afternoon members and friends inspected the new quarters.

The Automobile Club of Philadelphia's building formally dedicated this afternoon represents the growth of an agitation inaugurated years ago for the ownership of a building containing a garage for the use of members. The building is a handsome fireproof concrete and steel structure occupying a lot containing 3-4 acre. The entire front, extending 237 feet along Twenty-third street south of Market, is wired glass enclosed in steel framework, giving the interior of the building perfect natural lighting facilities during the daytime. The lot has a depth of 140 feet.

Location of Club Ideal

The location is an ideal one, being on the traveled line to the business section of the city, Broad street and Fairmount Park, and is readily accessible to all the outlying districts. As at present constructed the building is three stories in height, each floor containing 30,000 square feet of space. Ultimately it will be six stories high, with an estimated capacity for storing 750 automobiles. In addition the building is equipped with every modern convenience and necessity, which include spacious club rooms, offices and board of directors' quarters, perfectly appointed chauffeurs' quarters provided with lounging rooms, wash and bath rooms; repair and machine shops, and the like.

The club is one of the most influential in the automobile world, and in connection with its activities operates a touring information bureau, law and ordinance bureau, a co-operative supply bureau, and issues a monthly bulletin and yearly route book. Born in 1901, the organization has grown from an initial membership of sixteen, occupying a single room on the top floor of the Manufacturers' Club, to a present membership of 1,600, the largest in Pennsylvania and one of the largest in the country. Powell Evans, as chairman of the finance and construction committee, was most active in carrying the plans for the present magnificent structure to completion.

The officers of the club are: Powell Evans, president; Howard Longstreth, vice-president; S. Boyer Davis, secretary, treasurer and counsel. Board of directors: Powell Evans, S. Boyer Davis, Henry P. Baily, Jacob J. Seeds, Stedman Bent, Winfred J. Foss, Howard Longstreth, Robert P. Hooper, W. O. Griffith, J. Hartley Merrick, W. W. Atterbury and Charles W. Pickering, Jr.

The chairman of the various active committees are: Law and ordinance, S. Boyer Davis; touring information, W. O. Griffith; good roads, Howard Longstreth; membership, Henry P. Baily; finance and construction, Powell Evans; supplies Winfred J. Foss, and garage, Powell Evans.

Machine Tools Transferred to Garden

Preliminaries in preparation, decoration and arrangement for the annual automobile show have been taken up in earnest and despite the fact that Madison Square Garden is scheduled to be used for a big ball the week before the opening of the show the actual work is going forward rapidly. Some of the principal decorations will be installed before the ball. The chief change announced in the show program is the transfer of the machine tool exhibit from Grand Central Palace to the Garden. It was intended to place this interesting feature of the show on the balcony floor of the Palace but it was learned that on account of the floor structure it would be necessary to reinforce the underpinning and to do other expensive work in order to make the exhibit there a possibility. Therefore the management decided to transfer the machine tools to the Garden where they will be installed in the basement where there is a cement floor and where more space can be devoted to them. It is expected that at least a dozen concerns will take part in this section of the show.

PARIS, Dec. 17—Announcement has just been made that the Automobile Club of France, has selected a course for the running of the 1913 grand prix. The committee has selected a circuit in the vicinity of Amiens.

Washington Dealers Organize

WASHINGTON, D. C., Dec. 14—The motor car show proposition took a new angle this week when a number of the dealers met, organized and incorporated the Automobile Dealers' Association of Washington, the primary object of which will be to promote the show scheduled for February 3-8. The new organization will have complete control of the show. T. Oliver Probey was elected chairman of the show committee; C. W. Semmes, vice-chairman; E. A. Garlock, secretary; F. C. Sibbald, treasurer; governors, Arthur Foraker, J. H. Miller, F. W. Robartes, I. J. Henderson, J. H. Earle, T. Lamar Jackson, Bruce Emerson.

Additional Exhibitors for Big Shows

The following concerns, members of the Motor and Accessory Manufacturers, have been assigned space, in addition to those already reported, for the New York, Chicago and Boston automobile shows mentioned:

Madison Square Garden, New York

First and Second Week

Baldwin Steel Company, 30 Church Street, New York City.
Dean Electric Company, Elyria, O.
Findeisen & Kropf Manufacturing Company, Twenty-first and Rockwell Streets, Chicago, Ill.
Homo Company of America, 3202 Oxford Street, Philadelphia, Pa.
McCue Company, 1700 Elmwood avenue, Buffalo, N. Y.
New Departure Manufacturing Company, N. Main street, Bristol, Conn.
Warner Instrument Company, 689 Roosevelt street, Beloit, Wis.

First Week Only

Detroit Electric Appliance Company, 264 Jefferson avenue, E., Detroit, Mich.
Electric Auto-Lite Company, 133-137 Michigan street, Toledo, O.

Grand Central Palace, New York

First and Second Week

Dean Electric Company, Elyria, O.
Homo Company of America, 3202 Oxford street, Philadelphia, Pa.
U. S. Light & Heating Company, 30 Church street, New York City.
Westinghouse Electric & Manufacturing Company, E. Pittsburgh, Pa.

Second Week Only

Hess Steel Castings Company, Bridgeton, N. J.

Chicago

First and Second Week

Baldwin Steel Company, 30 Church street, New York City.
Detroit Electric Appliance Company, 264 Jefferson avenue, E., Detroit, Mich.
James L. Gibney Rubber Company, 215-217 N. Broad street, Philadelphia, Pa.
C. T. Ham Manufacturing Company, 731 Oak street, Rochester, N. Y.
Homo Company of America, 3202 Oxford street, Philadelphia, Pa.
Pittsfield Spark Coil Company, Dalton, Mass.
A Schrader's Son, Inc., 28-32 Rose street, New York City.
Westinghouse Electric & Manufacturing Company, E. Pittsburgh, Pa.

First Week Only

Dean Electric Company, Elyria, O.
McCue Company, 1700 Elmwood avenue, Buffalo, N. Y.

Boston

First and Second Week

Dean Electric Company, Elyria, O.
James L. Gibney Rubber Company, 215-217 N. Broad street, Philadelphia, Pa.
Homo Company of America, 3202 Oxford street, Philadelphia, Pa.

First Week Only

Gabriel Horn Manufacturing Company, 970 Hamilton street, Cleveland, O.
Hood Rubber Company, 99 Bedford street, Boston, Mass.
McCue Company, 1700 Elmwood avenue, Buffalo, N. Y.

Digest of Leading Foreign Journals

(*Continued from page* 1264.)

exhaust port *p* leads directly to the atmosphere, and the spark-plug *g* is secured nearly diametrically opposite to it in A. The flywheel, which may be a propeller, is mounted upon a piece which is made integral with A.

When functioning, the two pairs of pistons are alternately moved toward and away from one another, imparting a scissors movement to the plates *a* and *b* as well as to the cross-levers *ee* and *ff*, and the variations produced by this movement in the annular expansion chambers correspond to the phases of an eight-cylinder, four-cycle motor.

In Fig. 8, the two pistons are shown as close together as they can get, the movement being limited by the diameter of the pinions *h i*. When the spark-plug passes the space between them in this position, the charge is fired—this feature being easily regulated in connection with the stationary gear work of the motor—and the pistons are driven apart, causing the tore A to rotate at the same time, and when they reach the limit of the stroke the exhaust port passes into communication with the larger annular space now separaing pistons *a*1 and *b*1, and the exhaust begins while A continues to turn in the same direction as before. The end of the admission stroke is indicated in the position of the lever arms in Fig. 9. As said, an explosion occurs each time the spark-plug passes an explosive mixture compressed between two pistons; that is to say that it occurs four times during one revolution of A; namely, in the positions marked 1, 2, 3 and 4 in Fig. 8. It is stated that arrangements have been made for the manufacture of this motor (with regard to the construction of which more precise data may be expected) in sizes up to 300 horsepowers.—From *La Vie Automobile*, Nov. 23.

EXPLOSIONS of Oxygen Containers—A number of explosions are reported to have occurred at small autogenous welding establishments in different parts of France incidentally to the use of tubes containing oxygen under strong compression. An investigation of these accidents disclosed the fact that in all cases the oxygen had been produced by electrolytic action upon water and that it was impure, containing from 3 to 10 per cent. of hydrogen. It has been proposed to place the manufacture of compressed oxygen under public supervision, so as to insure its purity and consequent harmlessness, and it is contended that under proper safeguards it may be manufactured from water as well as by other methods.—From *Revue de la Soudure Autogène*, November.

Milwaukee Decides On One 1913 Show

Entire Motor Trade of the City Will Unite to Promote—Exhibition To Be Held in the Auditorium

Eighty-Five Pleasure Cars in 225 Models of Various Makes To Be Shown January 11 to 17

MILWAUKEE, WIS., Dec. 17—After a week of turmoil, during which a new organization of dealers was actually organized and articles of incorporation filed; an exposition hall leased for a second motor show to compete with the regular Milwaukee show, and several skirmishes in a warfare between two factions of dealers fought, it was announced on Monday that there will be but one motor show in Milwaukee for 1913, and it will be promoted with the united efforts of the entire motor car trade of the city.

A week ago today the Milwaukee Motor Show Association, organized by members of the Milwaukee Automobile Dealers' Association, and incorporated without capital stock, issued blanks for space in the 1913 Milwaukee show, to be given from January 11 to 17 inclusive in the Auditorium. The blanks were issued to all of the dealers in Milwaukee, about sixty in number, of which twenty-two are affiliated with the M. A. D. A. Tuesday night twenty-four of the dealers who are not affiliated met in the office of Hustis Bros., and organized the Milwaukee Progressive Automobile Dealers' Association, the principal object of which was to conduct a motor show according to its own ideas of how a motor show ought to be run. A tentative lease was made with the management of the Hippodrome, an exposition palace of lesser proportions than the Auditorium, which, by the way, was the home of Milwaukee's first motor show, when the Milwaukee Automobile club started the ball rolling in 1908. The tentative dates were January 11 to 17 inclusive, or the same period set for the regular show of the Milwaukee Motor Show Association.

It appears that the progressive dealers were dissatisfied with the conditions made by the motor show society and determined to run their own show on a co-operative plan. The progressives or insurgents claim that not only was the price per space increased 50 per cent. over that charged at the 1912 show, but certain other conditions were imposed which made it advisable for them to get busy and run their own exposition.

As soon as the progressives announced their plans, the regular organization got busy and negotiated for a compromise, so that Milwaukee would not be called upon to support two shows at the same time, a condition which might result in either two failures or two successes. The conferences lasted over Sunday, and on Monday it was announced that a compromise had been effected and there would be but one exhibition, supported by the combined forces of the Milwaukee dealers, representing about eighty-five or ninety pleasure cars of various makes, to be shown in no less than 225 models on the floors of the numerous halls and annexes of the mammoth Auditorium building.

Ghent Show Will Have Strict Rules

BRUSSELS, Dec. 5—The announcement that both French and Belgian Societies of Motor Manufacturers are arranging collective displays of motor cars for the international exhibition to be held at Ghent next year, and have already booked space for their exhibits is of much interest. The conditions of display are of the most stringent nature and the authorities stipulate that no manufacturer or agent will be permitted to show a foreign body on a Belgian chassis nor the reverse.

Within the Walls of Paris

(*Continued from page 1255*)

method, continues it; La Buire has adopted it, and it is very much favored by the Italian firms, S. C. A. R., S. C. A. T., etc. De Dion-Bouton makes use of it on some of the smaller models. Although not likely to oust separate construction in the near future, the unit idea has made real progress. There are two distinct methods of treating the unit type. In the minority is the Hispano-Suiza school, where the unit is rigidly bolted to the frame or to inswept extensions of the frame so as to stiffen the entire construction, and in the majority of cases the unit is hung on three points.

Tendency Is Toward Monobloc

The tendency is more and more toward monobloc motors, some of the four-cylinder castings being enormous pieces. Berliet, for instance, has cylinders of 100 by 140 cast together; Gregoire has changed from pair casting to bloc; Delage casts six cylinders of 65 by 130 together; La Buire has single castings up to 90 by 160. Practically all motors up to 85 bore are in one casting, above this size opinions are divided, the majority favoring pair casting. Single casting is practically unknown except by some of the firms using the Knight motor in big sizes.

Silent-chain drive for cam and magneto shafts has made enormous progress. It would perhaps be easier to give the names of the firms not using it than those having adopted it. The former list would include some important firms, for it is precisely those factories having such a reputation that they can afford to be conservative which have remained true to meshing pinions. Panhard, usually classed with the conservative school, has made use of a chain for the poppet-valve models, after having had lengthy experience with it on the Knight motors. Sizaire-Naudin, after using it on one model, has extended it to all. Chenard-Walcker uses it throughout the series, from the small four to the big six.

The use of one or two chains and the provision for adjustment or not are debatable points. The majority appear to have made use of a single chain on three points, one of these—the magneto-shaft—being adjustable. It is the method adopted by Chenard-Walcker, where the magneto platform has a transverse adjustment to take up the slack of the chain. The same idea is used by Ballot on most of his motors. Delage, on the other hand, prefers the use of two chains, crankshaft to camshaft and camshaft to magneto shaft, without adjustment. **The main feature is that after a couple of years' experience chains have not given trouble, are being continued by those having tried them, and taken up by others.**

Thermo-syphon cooling is in a majority, if the exhibition as a whole is considered. But if the cars are separated into classes it will be found that pump and natural flow are about equally divided for the more powerful motors. Hotchkiss, Delaunay-Belleville, Panhard, Unic, Peugeot retain the pump for all their models or at any rate for all those of more than moderate power. The claim is no longer made that natural circulation is inefficient under strenuous conditions, but the claim is made that for very big motors the quantity of water that must be carried outweighs the advantage of abolishing one supplementary organ. Renault and Charron still head the list of firms making use of thermo-syphon for the whole series of motors.

High-Tension Ignition Best

There can only be one opinion regarding ignition. A single high-tension magneto, with fixed advance in the small powers and variable advance for the larger models, is found on at least 95 per cent. of the cars in the show. Storage batteries for ignition purposes are as dead as the dodo. Even the attempts to popularize a double ignition with one set of plugs, as brought out a couple of years ago, has failed to find favor. In most cases this was fitted with a view to starting up on the switch, but results were so uncertain, some motors starting well and other equally good makes refusing to start except under most favorable circumstances, that it was usually not considered worth while to keep a battery in service. It should be borne in mind that European motors, as a rule, are of comparatively small size, and the cranking of them does not present any great difficulty. Both magneto and carbureter manufacturers have made it their business to build appliances which make for easy starting, and as to the possibility of a breakdown, the average European motorist looks upon his magneto as the most reliable piece of mechanism on the car. Automatic advancing magnetos have not made much progress. Fixed-point ignition is in the majority, but this is merely because of a desire to make the car foolproof. In the higher-grade cars, generally handled by skilled men, it is the custom to fit variable spark advance.

Continental Europe manifests a decided lack of enthusiasm for the self-starter. All automatic methods of starting up the motor complicate the car, and so long as the craze is for extreme simplicity and clean-cut lines a mechanical starter will not find much favor. There is the fact, too, that the

European car owner rarely goes out without a mechanician, and there is a natural feeling that as the man is paid wages he might as well earn them. If cranking occasioned a serious delay, the owner would doubtless be willing to put down extra money to save time; but so long as it calls for an effort during but a few seconds, money will not be spent to save the driver this amount of labor. At present Delaunay-Belleville appears to be the only manufacturer making a specialty of a mechanical self-starter, but even in this case it is only fitted as an extra and does not find its way to the majority of cars of this make.

Electric lighting is considered a much more desirable feature than a self-starter. There is this difference, however, between European and American practice that in the former case the lighting outfit is generally an added accessory for which provision has been made in the original design of the chassis. This is explained by the fact that in Europe only the cheaper and medium-priced cars are sold all complete for the road, and in order to keep prices low these cars are fitted with ordinary oil lamps. The higher grade cars, which when completed always have electric lights, are sold by the manufacturer as a chassis and have their bodies made to order by a coach builder. Panhard, for instance, now specializes on a couple of series of completely equipped cars, and on one of these chassis there is a platform for an electric lighting dynamo and a pinion for driving it by silent chain. When catalogued, however, the car is given with oil lamps. This appears to be the general method of dealing with the problem in continental Europe.

Firms Still Make Many Models

So far as France is concerned, the average number of models per firm has not shown any decrease. The old idea was that each firm should have a sufficient range of models to satisfy every client from the poorest to the richest. Renault is a conspicuous example, with cars varying from two small-cylinder cars to six big-cylinder ones. Certain firms, having attempted to follow this example, have not failed to discover its disadvantages, and with a view to cutting down overhead charges have abolished the models for which there was the least demand.

The matter has been given a lot of attention by French manufacturers and some unsuccessful attempts have been made to mutually agree on what types of cars should be produced by each firm. This ambitious scheme having failed to materialize, a certain number of manufacturers have reduced their number of models, while others are continuing the full range with special attention to one particular type. Delage has cut his models down to three, a couple of fours and a six; Chenard & Walcker has got the number down to four, of which three are fours and one a six; Darracq has abolished some of the larger models, now specializing on three four-cylinder types; and De Dion-Bouton has cut out all singe-cylinder models, one of the twins, and while having a big series is specializing on a small four and a small eight. This firm, by the bye, is the only one paying attention to eight-cylinder motors. Panhard is more interested in the high-class trade, but is now specializing on one poppet type and one non-poppet, sold fully equipped for the road.

Renault, after an extensive tour through America, has come back with the intention of building one of his models, rated at 11 horsepower and having a bore and stroke of 75 by 120, on American lines, and is putting it on the market next year fully equipped for the road. The equipment consists of four-passenger body, top, wind screen, tires, horn, lamps and tools. The price has not yet been announced.

Some Have Increased Their Types

In contradistinction to these firms having either cut down to their number of models or specialized on one or two, there are certain firms having increased their types. This is largely owing to the fact that they have adopted non-poppet-valve motors without abandoning any of their poppet-valve types. This is the case with Gregoire, having replaced a twin by a small four, put on an additional Knight motor and prepared to put a larger Knight on the market. Morse has taken up the Knight with the same results, there now being four non-poppet-valve models and four chassis of similar design equipped with the sleeve-valve motor. Peugeot, instead of decreasing has increased the number of models by reason of a desire to use worm drive on two new types without abandoning bevel drive. **Despite these contradictions, the indications are, however, towards a reduction in the number of models produced by each firm.** It is recognized that overhead charges can be reduced by this method and it is more a matter of convenience than principle in making the change.

The outstanding feature of the non-poppet valve situation is the increase in the number of Continental firms having adopted the Knight motor. Panhard & Levassor, holding manufacturing rights for France, are now building but two models with the poppet-valve motor, these being small types of 2.7 and 5.5 inches bore and stroke

and 3.1 by 4.3 inches bore and stroke. All other models have the Knight sleeve-valve motor. Mors, Gregoire, Aries, Rossel and Clement-Bayard have secured licenses for the sale of the Knight motor and are fitting it to some of their chassis for the coming season. Mors has made arrangements for bringing out four Knight motors, the respective bore and stroke being 2.9 by 4.7, 3.5 by 5.1, 3.9 by 5.5 and 4.8 by 5.9 inches. These are in addition to four poppet-valve models, making eight models in all, but as the chassis dimensions are the same for a Knight and a poppet-valve type it is practically a case of four chassis with four alternate types of motors.

It is worth noting that the 2.9 by 4.7-inch motor is the smallest Knight type sold in France, most of the firms making their small motors with poppet valves and only the larger and more expensive types with the Knight motor. The Mors power plants are supplied by the Minerva factory, in Belgium.

Gregoire to Build Big Knight

Gregoire has at present only one model of the Knight on the market, this being a four-cylinder of 3.1 by 5.1 inches bore and stroke fitted in a chassis having worm-driven rear axle. It is intended, however, to produce a larger type at an early date, and in all probability the proportion on Gregoire-Knights will be about one-quarter of the total output. In this case the Knight power plants are imported from the Daimler factory at Coventry.

Clement-Bayard is building two Knight types for 1913, or respectively 3.5 by 5.1 and 3.9 by 5.5 inches bore and stroke. Four other models, of smaller size, are made with poppet valves.

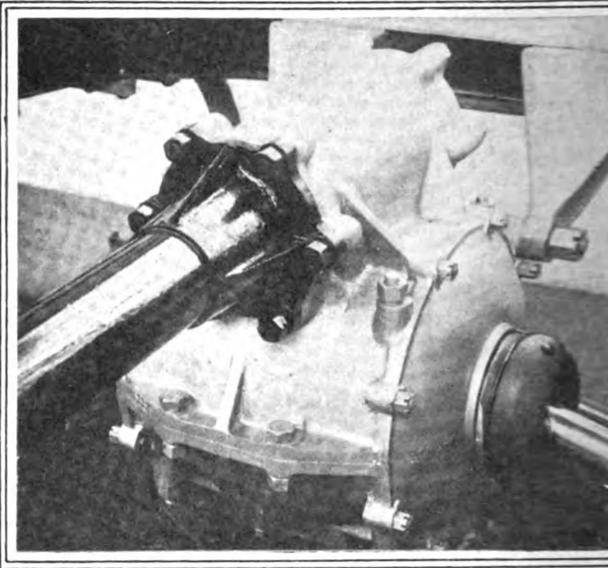
Rossel and Aries have made arrangements to equip some of their cars with the Knight motor, but particulars have not yet been given out.

The entire Minerva output now consists of Knight motors, this Belgian firm putting four distinct types on the market under its own name and building a number of power plants for other continental firms. Extensions giving 100 per cent. increased capacity and floor space have just been completed. The only other Belgian firm equipping its cars with the Knight motor is Germain. In Germany the rights are held by Mercedes and licenses have been secured by N. A. G. and the Kraftfahrzeug Aktien-Gesellschaft. In Austria Johann Puch has the rights and in Switzerland Knight motors are being marketed by Martini and the Sigma company.

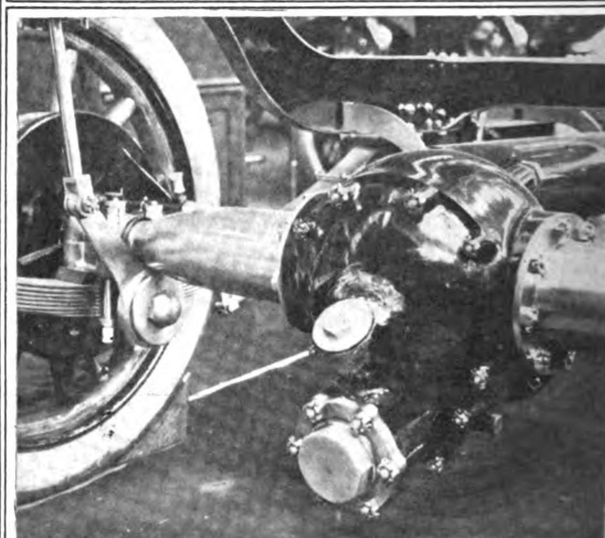
Non-poppet valve systems other than the Knight are being taken up very slowly. More than one case could be mentioned of French firms having purchased non-poppet valve patents, and tested them out only to abandon them. It must be admitted that the introduction to the European market of any rival of the poppet valve has now become a most difficult matter. Peugeot is now cataloguing a non-poppet valve type, but has not placed it on exhibition. Delahaye admits having a non-poppet valve model in preparation, but is not fixed as to the date of its public appearance. Those actually producing non-poppet valve motors are Darracq with the Henriod rotary-distributor model; Rolland-Pilain with a single-sleeve type; Piccard-Pictet with a license for the Argyll motor; Itala with a rotary distributor; Schneider with a ring-type applied to one model only; C. I. D. with a rotating-ring type, and C. L. C. with a rotary-sleeve model.

C. L. C. Now Is Four-Cylinder

The C. L. C. with a single-rotary sleeve has been produced for more than a year as a single-cylinder model, and is now being built in a four-cylinder of 2.5 by 5.1 inches bore and stroke. The sleeve has a single opening and carries a very deep compression ring having an opening corresponding with that in the sleeve. It is prevented from rotating on the sleeve by means of a stud. There are two ports for, respectively, intake and exhaust, the width of these ports being very much greater than the width of the openings in the sleeve; thus there is a certain period during which the opening remains constant, despite the continuous rotation of the sleeve. Each sleeve has near its base a spiral gear by which it receives its motion from a half-time shaft. Above and below this gear is a radial and thrust bearing. This double bearing adds to the cost, but it simplifies the assembly compared with previous methods of construction. By reason of these bearings at the base of the sleeves the overall length of the motor is increased, this explaining the single casting of the cylinders. Because of the length



De Dion worm-driven axle with overhead worm



Peugeot worm-driven axle with underneath worm

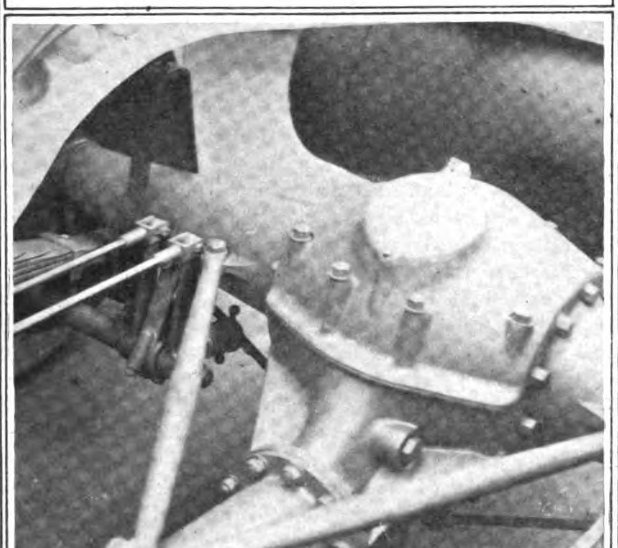
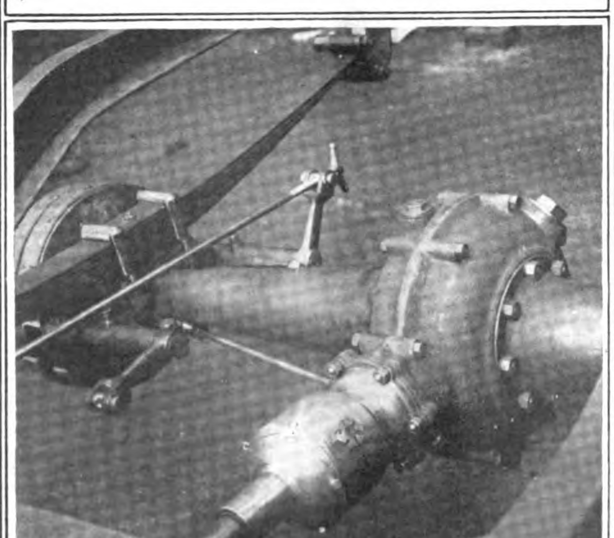
New Darracq axle with underslung springs



Sheffield-Simplex worm-driven axle—worm underneath



Sizaire-Naudin axle with ready brake adjustment

of the motor, five bearings are used for the crankshaft, this being quite unusual for a motor of such small bore. It has been decided, however, to fit only three bearings for the standard models. The half-time shaft occupies the position usually given to the camshaft, but instead of being within the crankcase it is mounted on radial ball and thrust bearings within an independent housing bolted to the crankchamber. As there is silent-chain drive from the crank to the secondary shaft, it is only necessary to take off the nuts on the holding-down studs, place the Oldham coupling horizontal, and withdraw the entire shaft with its bearings. By this arrangement it is possible to vary the timing of the sleeves with comparatively little difficulty.

C. I. D. Motor Unchanged

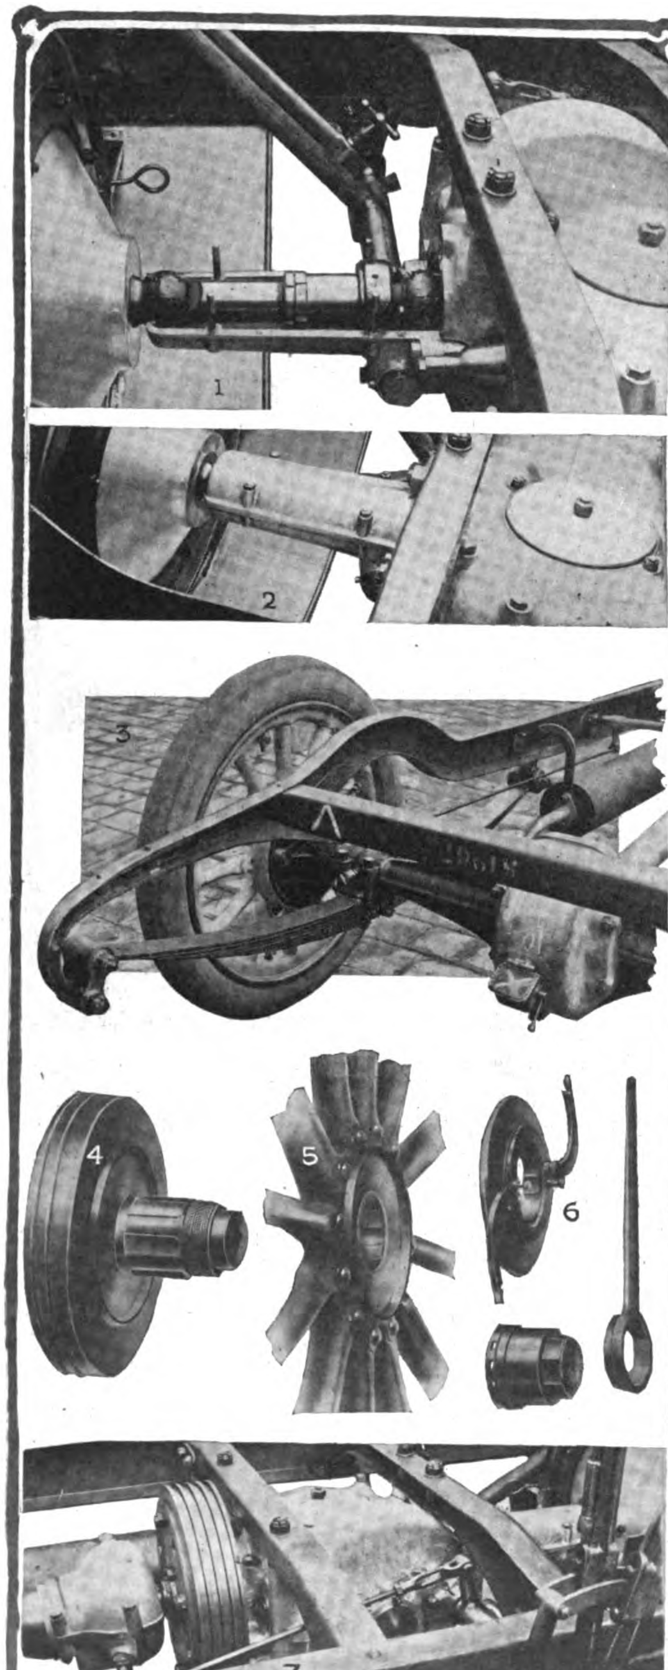
The C. I. D. non-poppet-valve motor has remained practically unchanged since its first appearance. It assured the intake of the fresh gases and the discharge of the spent gases by means of an extensible ring having a suitable opening, placed in the head of the cylinder and driven by a vertical spindle from an overhead shaft. The ring revolves at one-half motor speed, passing successively in front of the intake and the exhaust ports, and assures gas tightness by reason of its extensibility. The overhead shaft driving the distributer rings also drives the high-tension magneto, the distributer of the magneto being brought through the dashboard. The Constructions Industrielles Dijonnaise, holding the patents for this motor, produces one type only.

Renault has made important changes in the suspension of all his cars for the 1913 season. Instead of the rear underslung three-quarter elliptic springs employed on practically all models for the last 2 years, the new types will have long semi-elliptics seated under the axle. On the 16-horsepower type, 90 by 140-millimeter bore and stroke. The width of the springs is 2 5-8 inches and the length 57 inches. The frame is somewhat abruptly arched over the rear axle and downswept at the rear. The rearmost transverse member has arms which fit into the longitudinal frame members as far as the extreme rear, thus considerably stiffening this portion of the chassis. On the 16-horsepower model the rear springs have twelve leaves. The semi-elliptic springs have been adopted in order to eliminate the side sway which frequently set up with three-quarter elliptics, particularly when heavy closed bodies are carried. Shock-absorbers are made a standard fitting for the rear.

Renault, who has always been an opponent of detachable wire wheels, has now produced a detachable wood artillery type of wheel. The fixed hub carries keys corresponding with grooves on the detachable hub, and also a large-diameter shoulder with a taper to correspond with a tapered shoulder on the detachable hub. When the wheel has been placed on the fixed hub, a deep ring is also mounted on the keyways of the shaft. This ring carries on its inner face a taper-section collar corresponding with a taper ring on the outer face of the detachable hub. Thus the entire wheel is centered on two cone seatings. It is locked on by the hub cap, which, after being screwed up, is prevented from being unscrewed by a couple of semi-circular arms pivoted to the outer centering ring and entering a groove in the cap. These form the final lock and are maintained in their locking position by a spring mounted pin passing into a slot in the extremity of each arm. A single spanner is required for locking the wheel or dismounting it. With the exception of the locking ring encircling the hub cap there is nothing externally to indicate that the wheel is not of the fixed type.

Clutch Shaft Is Inclosed

There are not many new features on the chassis. Probably the only one of importance, with the exception of the springs, is the incasing of the clutch shaft in order to protect the universals from dust and to allow them to run in oil. An aluminum housing divided horizontally into halves is bolted to the front end of the gearbox around the shaft between the gearset and the clutch. The forward end of this tubular housing has inturned lips, thus preventing lubricant leaking out, unless, of course, it rises above the level of the lip. Within the upper portion of the housing there is an oil lead allowing lubricant from the gearbox to drip onto the universal joints. A return pipe in the lower portion allows this lubricant to drain back into the gearbox. The foot brake to the rear of the gearset is now of the expanding type, the drum being



Some 1913 Renault Constructions

7—New method of supporting gearbox beneath frame

ribbed. The gearbox is bolted to the underside of a couple of upswept transverse frame members. On the motor the only change appears to be the fitting of a breather between each pair of valves in order to relieve pressure at this point and prevent the leakage of oil through the valve-tappet guides which very frequently occurs on some motors.

Panhard Has Four Models

The Panhard is making four models, two of the Knight sleeve-valve type and two small models with poppet-valve motors. Although generally classed as conservative from a pioneering viewpoint, the Panhard shows aggression in many respects. Chain drive, which has been used on the Knight motors for the eccentric shaft, is introduced on the two poppet types for camshaft and magneto-shaft drive. All models are made with a unit motor and gearbox. In spite of the fact that Europe is going stronger to two-bearing crankshafts the Panhard uses three. At the same time, while the majority of the manufacturers are introducing thermo-syphon cooling, the Panhard remains with a water pump on all models. The company has taken for next year its first important step in long-stroke motors in its new small 10-horsepower, four-cylinder type, 2.7 by 5.5 inches bore and stroke, which is a stroke-bore ratio of 2 to 1. This model replaces a twin-cylinder chassis of 3.1 by 4.7 inches bore and stroke. Unit construction is adopted, but this is not altogether new, for one of the larger Panhard models was so built a year ago. The cylinders are a bloc casting with a three-bearing crankshaft. Pump water circulation is employed. When these small series were first produced thermo-syphon flow was adopted, but it was quickly dropped in favor of forced water circulation, and all Panhard models now carry a water pump. The valve-operating mechanism is somewhat unusual. Valves are all on one side, with a large-diameter plug over each pair; the camshaft with integral cams is driven by a silent chain and a transverse shaft drives the magneto and water pump. The pushrods are not fitted with the usual type of guides; they are long steel rods with hollowed heads receiving the end of the valve stems and are maintained at their base in the hollow portion of an intermediate arm between the cam and the pushrod. The shape of the top of the crankchamber is such that oil leaking out through the pushrods will drip back again without overflowing down the sides of the crankchamber. Each pair of intermediate arms between cam and tappet is secured in a circular plate on side of crankchamber and held on their seat by a clamp. Thus, when the valves have been taken out, the tappets can be withdrawn without touching any other part. This is a considerable advantage.

Improvements in Lubrication

The lubricating system is new in its details. There is a trough under each connecting-rod in which the oil level is maintained just high enough for running light. On the wall of each compartment of the crankchamber is an inclined, open oil lead cast with the chamber, and serving to lead the oil splashed up in one chamber to the adjoining chamber, the oil thus passes from the rearmost or fourth cylinder to the third, then to the second, and finally to the first. Naturally the inclination of the oil lead on the wall of the crankchamber is such as not to interfere with the flow when the car is on a gradient. In the portion of the crankchamber corresponding to the first cylinder, the oil lead is replaced by a pocket which gathers the oil splashed on the walls and returns it to the reserved oil tank cast in the right-hand crankcase hanger. The used oil, however, does not mix with the fresh supply, but is received in a funnel in the tank, is filtered and passed through a pipe to the rear compartment of the crankchamber. By means of the filler cap on the reserve tank it is possible to verify the flow of the oil. In the base of the tank already mentioned as being cast in the crankcase hanger is a needle valve connected up to the accelerator pedal. Thus, as the throttle is opened this valve is raised from its seat and oil allowed to flow down the return pipe to the trough for the fourth cylinder. On the carbureter side of the motor there is a connection between the throttle and the oil feed,, while the filler cap for the reserve oil tank is placed immediately to the right of it. The connection mentioned regulates the flow of the oil at varying motor speeds.

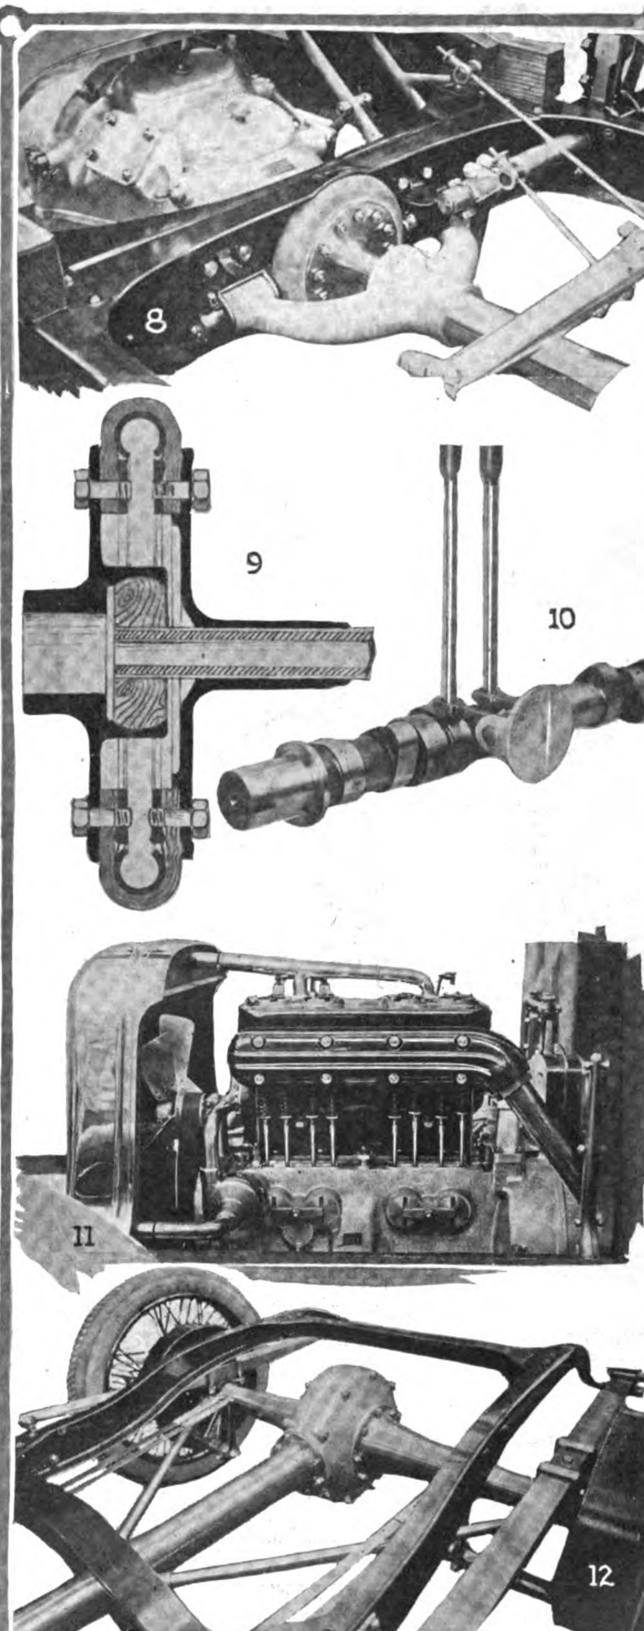
An entirely new feature is the single joint at the rear of the gearbox, with drive shaft to an oscillating type of rear axle formed of two taper tubes and a central aluminum differential housing. The universal joint is used for the first time by Panhard and consists of a rubber-and-canvas connection construction having a very close resemblance to a pneumatic tire having one of its heels secured to a disk mounted on the secondary shaft of the gearset, and the other heel secured to a plate on the propeller shaft. This allows a certain freedom of movement of the two shafts in relation to each other, without, however, preventing the second being driven by the first. This joint is known by the Panhard engineers as a flector and is built up of canvas and rubber in practically the same way as a tire; the canvas, however, is laid in the opposite way to that of a tire in order to provide for the driving effort. In order that the flector may retain its circular form a band of steel is placed inside it and the two shafts are centered by a hardwood block, so that the flector has not to carry the weight of the shaft. On this model both brakes are on the rear wheels, side by side within a single drum. This is a construction now applied to all Panhard models.

De Dion Favors Worm Drive

De Dion-Bouton is introducing worm-driven rear axle on the majority of its new models, and is also fitting wire wheels with wood wheels as optional, the hub construction being such as to permit of the optional wood wheels. The company is specializing on a high-grade eight-cylinder chassis with worm-driven rear axle. The car is really a modification of last year's small eight cylinder type. The principal change in the motor is an increase of bore from 2.7 to 2.9 inches, the stroke being 5.1 inches, as last year. The motor is V-type with each set of cylinders forming a single casting and all accessories—magneto, air pump, carbureter—mounted between the two lines of cylinders. The method of driving the motor accessories is interesting. On the fore end of the crankshaft there are a couple of pinions giving chain drive to the oil pump in the base, and to the camshaft immediately above the crankshaft. On the camshaft there is a second pinion with chain drive to the ventilator shaft. Thus in this housing there are three separate chains. At the rear of the motor a pinion on the camshaft drives the magneto and air pump by means of a silent chain. The crankshaft is carried in two plain bearings, the crankcase having bolted on end-plates, steel pistons are used, and, as on all De Dion-Bouton models, lubrication is under pressure through a hollow crankshaft.

Details of Power Transmission

Interest centers in the manner in which the power is transmitted to the road wheels. The plate clutch is unchanged except in details. There is a universal joint between it and the four-speed gearbox, this latter having the two shafts in the same vertical plane and selective type without the use of a gate. Immediately to the rear of the gearbox there is a very substantial universal joint and a similar joint at the rear end of this shaft. This shaft is divided in the center of its length, and the two parts united by a coupling. From the second universal joint the shaft is carried within a tubular housing bolted at its rear extremity to the upper portion of the differential housing and at the front attached to a tubular transverse member having its extremities received in the brackets carrying the spring hangers. The final drive to the road wheels is by the De Dion-Bouton system of transverse cardan shafts, and, so far as this portion is concerned, the car is similar to last year's bevel-gear model. Three-quarter elliptic springs with their seatings under the axle are used on all De Dion models. In the steering gear the change comprises adjustable steering pivots.



Some 1913 Panhard Constructions

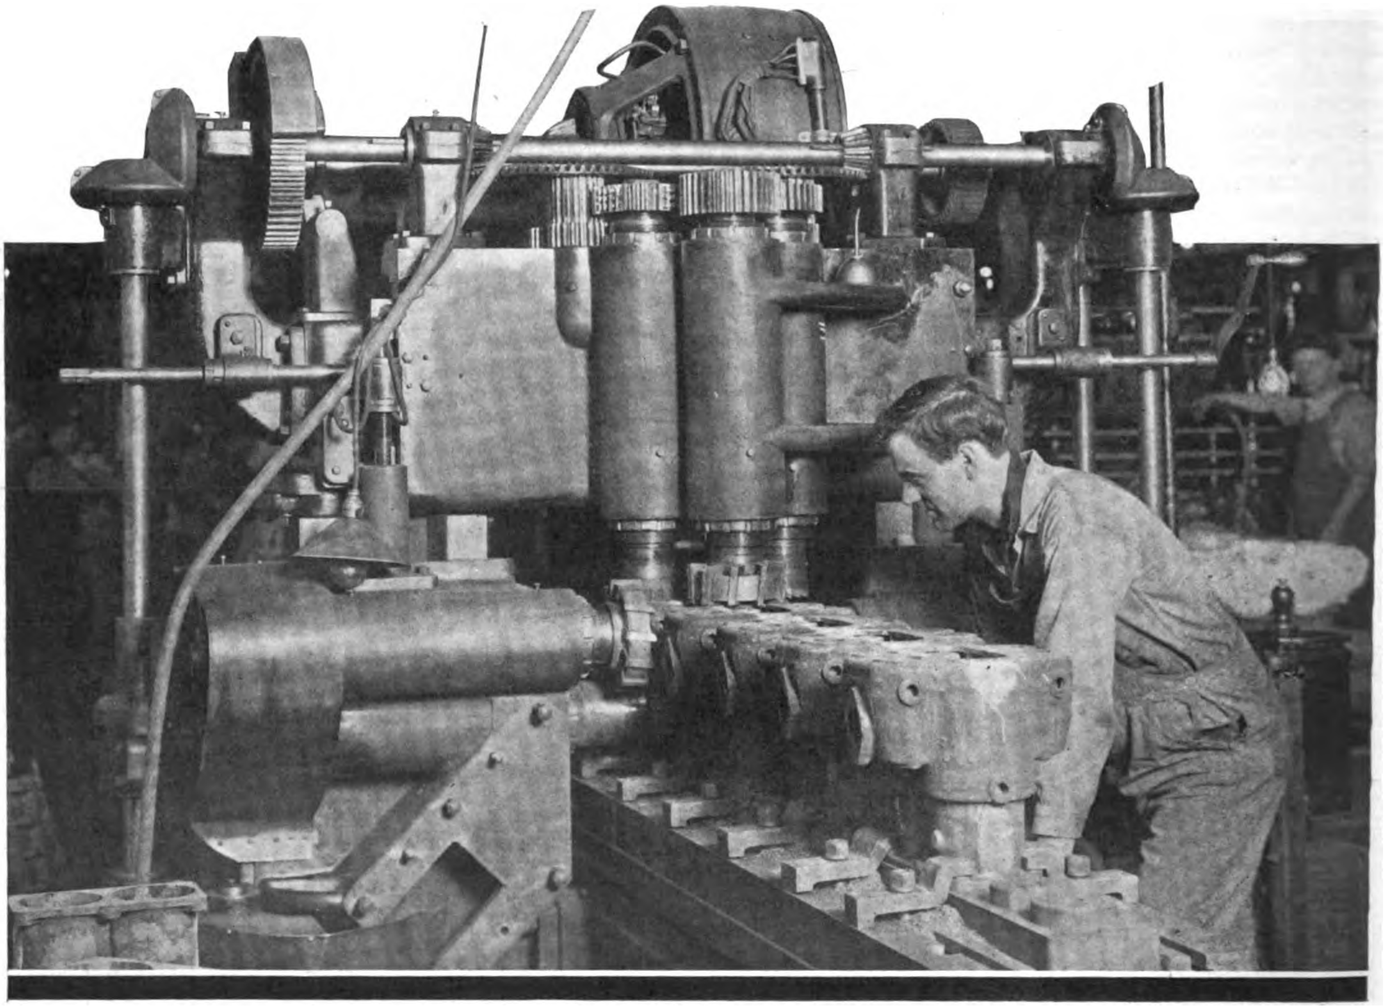
8—New pneumatic-tire type of universal in rear of gearbox, and 9 shows a section of this joint

10—Camshaft and valve tappets without guides in new 12-horsepower motor

11—Valve side of motor, showing tappet scheme

12—New axle with aluminum differential housing

Factory Miscellany



Cylinder-grinding machine in use at the factory of the Packard Motor Car Company, Detroit, Mich.

CYLINDERS of the T-head type have to be milled on both sides as well as on top. This is one of the things that makes them more expensive to manufacture than cylinders of the L-head type. In the Packard plant the cylinders are milled on both sides and on top at the same time, thus saving time and reducing the cost of manufacture to about the same as an L-head cylinder as far as the milling work is concerned. The machine shown in the above illustration can handle eight cylinders at a time. One man can handle the machine and set up the work and the machine can be worked a full 10 hours a day. The time required to finish a block of cylinders is eight minutes and the time required in setting up the work is negligible because a new casting can be inserted while the machine is working on one of the others. As may be seen, there is a milling cutter at work on every part of the cylinder at the same time and the minimum amount of time is thus required to handle the work.

HARTFORD Suspension's Factory—The Hartford Suspension Company, Jersey City, N. J., will employ 400 men in its new factory which is nearing completion. The floor space is 28,400 square feet and it is 8 stories high. The accompanying illustration shows the factory

Beaver Plans—The Beaver State Motor Company, Portland, Ore., plans to build an automobile factory.

Maxwell Closes—The Maxwell-Briscoe Motor Company, South Auburn, R. I., has closed its plant and has notified its 100 employees that their services are no longer required. The company is shipping its equipment to New Castle, Ind.

Guide Lamp's Factory—The Guide Motor Lamp Manufacturing Company, Cleveland, O., has awarded a contract for the erection of a new factory in that city. The building will be 60 feet by 130 feet, two stories high. It will be made of brick, steel and reinforced concrete.

Michelin Adds to Plant—A large wing is being added to building number 14 at the plant of the Michelin Tire Company, Milltown, N. J. This addition comprises 46,540 square feet of floor space. The new wing is one story high with a second story of 18,770 square feet over one section. This building is of reinforced concrete. The roof is of saw-tooth pattern, light and ventilation coming from above.

Tire Filler Company Builds—The Canadian Tire Filler Company, Ltd., has just been formed and has built a large factory and show rooms at Sherbrooke, Que., to make this new product. The company has the sole Canadian right of the Day's resile filler and has perfected the article and brought the filling up to date. Branches will be opened at Montreal and Toronto when suitable premises can be found.

San Francisco's Truck—San Francisco, Cal., is again on the map as a motor manufacturing point. Lee Gillig, who has been identified with the automobile trade of that city for some years, has recently built a truck which shows some new and decidedly interesting features. It is so built that either solid or pneumatic tires can be used. The left-hand drive and center control are used. Fifty of these light trucks will be placed on the market in 1913.

Shows, Conventions, Etc.

Jan. 2-10..........New York City, Importers' Salon, Hotel Astor, Importers' Automobile Alliance.
Jan. 4-11.........Cleveland, O., Annual Automobile Show.
Jan. 4-11.........Montreal, Que., Montreal Motor Show, Drill Hall and 65th Regiment Armory.
Jan. 11-18.........Milwaukee, Wis., Annual Show, Auditorium, Milwaukee Automobile Dealers' Association.
Jan. 11-25.........New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.
Jan. 18-25.........Philadelphia, Pa., Annual Automobile Show.
Jan. 21-26.........Toledo, O., Annual Show, Exposition Building, Toledo Automobile Shows Company.
Jan. 25-Feb. 1.....Montreal, Que., Montreal Automobile and Truck Show, R. M. Jaffray, Manager.
Jan. 25-Feb. 1.....Providence, R. I., Annual Show, State Armory, Rhode Island Automobile Dealers' Association, Inc.
Jan. 27-Feb. 1.....Philadelphia, Pa., Truck Show.
Jan. 27-Feb. 1.....Buffalo, N. Y., Annual Automobile Show.
Jan. 27-Feb. 1.....Detroit, Mich., Annual Automobile Show.
Jan. 27-Feb. 1.....Scranton, Pa., Annual Automobile Show, Hugh B. Andrews.
Feb. 1-8..........Chicago, Ill., Annual Automobile Show, Coliseum and 7th Regiment Armory.
Feb. 3-8..........Washington, D. C., Annual Show.
Feb. 8-15.........Hartford, Conn., Annual Show, State Armory, Hartford Automobile Dealers' Association.
Feb. 10-15.........Chicago, Ill., Truck Show.
Feb. 10-15.........Minneapolis, Minn., Annual Automobile Show.
Feb. 10-15.........Ottawa, Ont., Ottawa Motor Show, Howick Hall, Louis Blumenstein.
Feb. 15-22........Albany, N. Y., Annual Show.
Feb. 15-22........Newark, N. J., Annual Automobile Show, First Regiment Armory, New Jersey Automobile Exhibition Company.
Feb. 16-23........Richmond, Va., Annual Show.
Feb. 17-22.........Kansas City, Kan., Annual Automobile Show.
Feb. 18-22.........Baltimore, Md., Annual Show, B. A. D. A.
Feb. 19-22.........Bloomington, Ill., Annual Show, Coliseum, McLean County Automobile Club.
Feb. 19-22.........Geneva, N. Y., Automobile Show, Armory, Louis Blumenstein.
Feb. 19-27.........Topeka, Kan., Annual Show.
Feb. 20-22.........Canandaigua, N. Y., Automobile Show, Louis Blumenstein.
Feb. 22-Mar. 1....Brooklyn, N. Y., Annual Show, 23rd Regiment Armory.
Feb. 24-27.........Kansas City, Mo., Truck Show.
Feb. 24-Mar. 1....St. Louis, Mo., Annual Show.
Feb. 24-Mar. 1....Memphis, Tenn., Annual Show.
Feb. 24-Mar. 1.....Cincinnati, O., Annual Show, Music Hall, Cincinnati Automobile Dealers' Association.
Feb. 24-Mar. 1.....Omaha, Neb., Annual Automobile Show.
Feb. 24-Mar. 1.....Paterson, N. J., Annual Show, Paterson Automobile Trade Association.
Feb. 26-Mar. 1....Fort Dodge, Ia., Annual Show.
Feb. 26-Mar. 1....Glen Falls, N. Y., Automobile Show, Louis Blumenstein, Manager.
March 3-8.........Pittsburgh, Pa., Annual Automobile Show.
March 3-18........Des Moines, Ia., Annual Show, Pleasure Car Section, Coliseum, Dealers' Association.
March 5-8.........Tiffin, O., Annual Show, Tiffin *Daily Advertiser*.
March 8-15.........Boston, Mass., Annual Automobile Show.
March 12-15.......Ogdensburg, N. Y., Automobile Show, Louis Blumenstein, Manager.
March 18..........Syracuse, N. Y., Annual Show, Syracuse A. A.
March 19-26.......Boston, Mass., Annual Truck Show.
March 20-24.......New Orleans, La., Annual Show, N. O. A. D. A.
March 24-29.......Indianapolis, Ind., Annual Automobile Show.
Jan. 6............New York City, Meeting Motor Dealers' Contest Association.
Jan. 14............New York, Beefsteak Dinner, Big Village Motor Boosters.
Jan 15............New York City, Banquet, Waldorf-Astoria, Motor and Accessory Manufacturers.
Jan. 16............New York City, Meeting, Hotel McAlpin, Society of Automobile Engineers.
Jan. 17............New York City, Banquet, Hotel McAlpin, Society of Automobile Engineers.

Race Meets, Runs, Hill Climbs, Etc.

May 30...........Indianapolis, Ind., 500-Mile Race, Speedway.

Foreign

Dec. 7-22..........Paris, France, Paris Automobile Show, Grand Palais.
Jan. 11-22.........Brussels, Belgium, Annual Belgian Automobile Show, Centenary Palace.
March ....France, Sealed Bonnet 3000-Mile Run.
March 31..........Montevidio, Uruguay, International Competition of Agricultural Motor Vehicles.
April ....Barcelona, Spain, International Exhibition.

Petrolea Plans Addition—The Petrolea Motor Car Company, Petrolea, Ont., is having plans prepared for an extensive addition to its plant.

Brockway Receives Bids.—The Brockway Motor Company, Cortland, N. Y., is receiving bids for a one-story manufacturing plant 208 feet by 40 feet.

Jensen Building—Rasmus Jensen, of Los Angeles, Cal., has acquired a site at that city and will erect a plant for the manufacture of a patent carbureter.

Atlanta's $50,000 Plant—The Automobile Tire & Rubber Company, Atlanta, Ga., will install a plant in that city and will spend about $50,000 for machinery.

Studebaker Placing Contracts—The Studebaker Corporation, South Bend, Ind., is placing contracts for a factory in that city to be three stories and 50 feet by 120 feet.

Morgan & Wright Building—The Morgan & Wright Company, Detroit, Mich., is planning a factory addition in that city. It is to be concrete, three stories high and 250 feet by 94 feet.

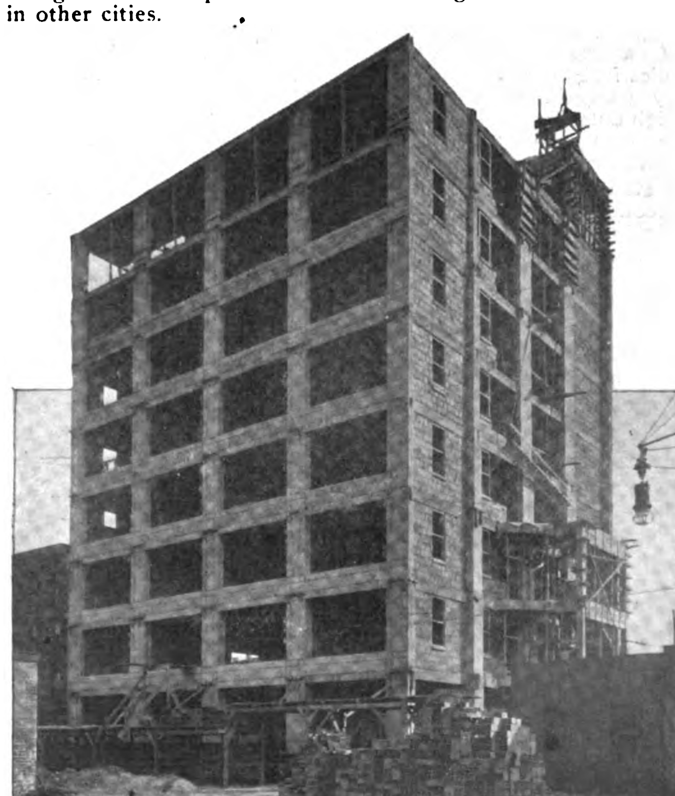
Ravenna Factory Started—The Ravenna Motor Truck Company, Ravenna, O., has given contracts for a factory to manufacture motor trucks. The building will be 50 feet by 150 feet.

Arrow's Factory—The Arrow Motor Car Company, Long Island City, N. Y., has filed plans for a four-story factory, 200 feet by 205 feet, with an extension of 54 feet by 51 feet. The estimated cost is $300,000.

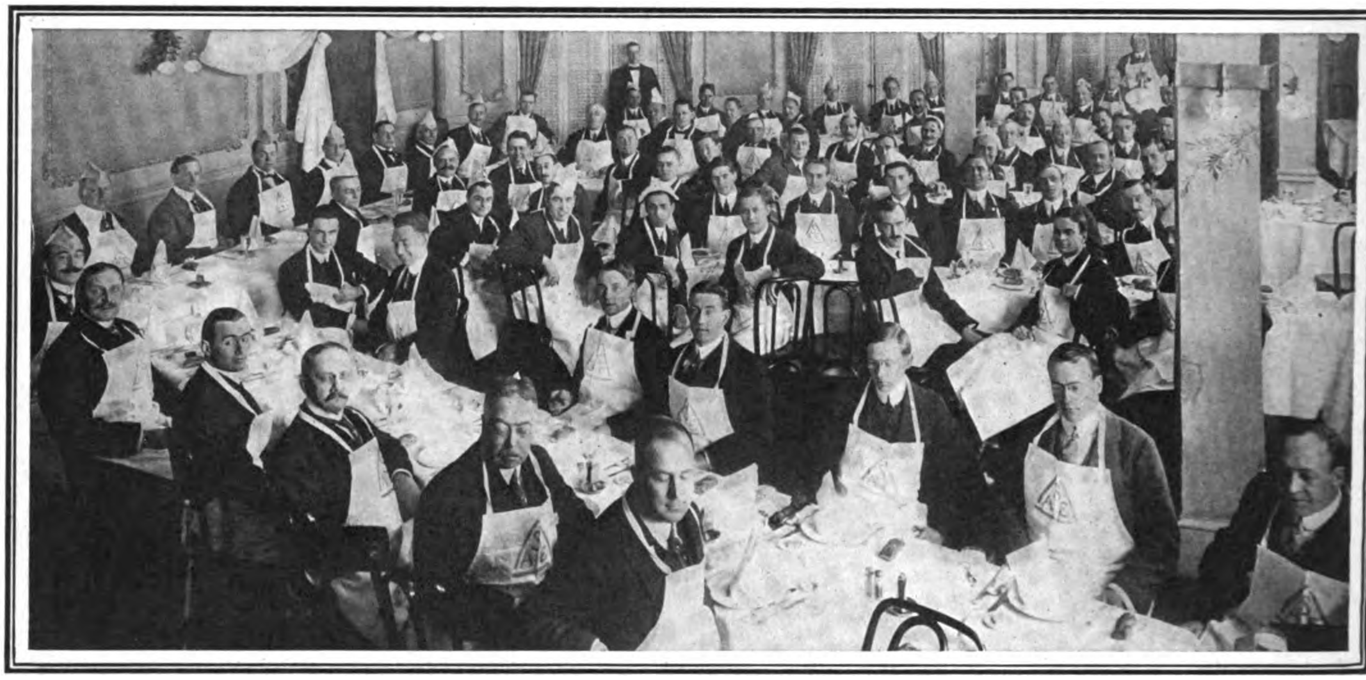
Ford's Long Island Factory—Bids have been given by the Ford Motor Company, Detroit, Mich., for a factory in Long Island City, N. Y. It is to be 70 feet by 195 feet by 75 feet, and is to be five stories high.

Sheboygan's Addition—The Sheboygan Auto & Supply Company of Sheboygan, Wis., will start work on the proposed addition doubling its capacity. It was intended to commence building operations in the spring of 1913, but the company has just taken the KisselKar agency, and this, with the enlargement of the Studebaker line, has made immediate action necessary.

Campbell Gets Contract—After much discussion as to whether the dealers' association would handle all arrangements for the automobile show or whether the management should be allowed to go to the person making the best proposition was decided by awarding the contract to T. C. Campbell. All decorations and allotments of space will be in his charge. Mr. Campbell has been in charge of similar events in other cities.



Eight-story factory of the Hartford Suspension Company, Jersey City, N. J.



Banquet of the Metropolitan section of the Society of Automobile Engineers on the evening of December 13 at George Rector's

AUTOMOBILES Admitted Free—In order to increase the number of automobiles in the Republic of Salvador the government has issued a decree admitting automobiles free of duty for a limited time. Cars are being purchased by a large number of wealthy families of the capital. The high duty assessed on luxuries in that country has added so to the cost of automobiles that the number of cars has been increasing very slowly.

Montgomery in Line—Montgomery, Ala., has installed its second motor-driven fire engine.

Join Ward Leonard Forces—Fay Morton Henkel and A. J Fisk have joined the sales forces of the Ward Leonard Electric Company, Bronxville, N. Y.

Paris Orders Fire Engine—In order to secure a lower fire insurance rate the city council of Paris, Tenn., has decided to purchase an automobile fire engine.

Kurtz with Ayer—F. W. Kurtz will return December 1 to Philadelphia, Pa., to resume his connection with the N. W. Ayer & Son advertising agency.

Opens Nyberg Salesroom—C. W. Bopp, formerly of Hawkeye, Ia., has opened a new salesroom in Des Moines, Ia., for the Nyberg Automobile Works of Anderson, Ind.

Cincinnati's Show—The automobile show in Cincinnati, O., will be held on February 24-March 1 in Music Hall. The directing heads of last season's show will be in charge of the coming one.

Annesley Diamond Manager—A. G. Annesley is the new manager of the Diamond Rubber Company in Portland, Ore., having recently been promoted from the San Francisco, Cal., branch.

Manufacturing Automobiles Chassis—The Nichoalds Company, Detroit, Mich., in the automobile parts business, has now gone into the manufacture of the automobile chassis for the trade.

Pettit Transferred—C. J. Pettit, of the Prest-O-Lite Company's New York Branch, has been transferred to Minneapolis, Minn., where he now has charge of three branches, Minneapolis, St. Paul and Winnipeg.

Mississippi's Good Roads—In a general election held in Hattiesburg, Miss., a tax to provide $100,000 for good roads carried with little opposition. Gravel will be shipped from Tennessee for surfacing the new highways.

Viehman Sales Manager—G. E. Viehman, head of the Viehman Automobile Company, agent for the Auburn Company, has returned to the Northwestern Automobile Company, Minneapolis, Minn., as sales manager.

Moon's Sioux City Building—The Motor Mart, the new home of the Bennett Automobile Supply Company, agency for Moon cars in Sioux City, Ia., has just been finished. It includes both a service department and a salesroom.

Shaw Resigns—D. M. Shaw, for 5 years identified with the MacManas Company, Detroit, Mich., advertising agents for this city, has severed his connection with that firm and will probably remain in that city in the same line of business.

Young Re-elected—The River-to-River Association, which was the pioneer in Iowa for a cross state road, held its annual meeting at Colfax recently. Lafe Young, of Des Moines, was re-elected president and B. N. Mills, of Des Moines, secretary.

Tacoma Club's First Meeting—With more than $200 to its credit and with $1500 dues payable December 1 for the first half of the coming year, and with the club incorporated and affiliated with the A. A. A., the only one so affiliated in the state of Washington, the first annual meeting of the Tacoma Automobile Club was held Tuesday, December 3.

Arranging Automobile Service—Arrangements are being made for the establishment of an automobile service between Cartago (Costa Rica), Neredia and Alajuela. Passengers, express and freight will be carried. The company holding the concession agrees to keep the road in repair in return for the exclusive right of operating such a line between the three points.

Arizona Law in Effect—The new state registration law of Arizona is now in effect. Under its provisions every owner of a motor vehicle must register each machine in the office of the Secretary of State. A complete description of each car, including the name of the make, factory number, style and motor power, must be given. The registration fee is $5 for a machine of 40 horsepower or less.

COMMERCIAL VEHICLES

Bowling Green, O.	Modern	Landman-Griffith Motor Co.
Minneapolis, Minn.	Hewitt	Twin City Motor Co.
Minneapolis, Minn.	Mack	Twin City Motor Co.

Warehouse in Atlanta—The H. W. Johns-Manville Company, New York City, has recently opened a new southern warehouse at Atlanta, Ga. The entire building, embracing three floors and a basement, with a total floor area of about 10,000 square feet, will be utilized exclusively as a warehouse.

Moline's Fire Apparatus—Automobile fire-fighting apparatus will shortly be installed by Moline, Ill., according to recent action of the city council. An automobile for the fire chief, two combination automobile fire engines and hose wagons and 75-foot aerial truck will supplant the present horse-drawn apparatus.

Stewart's Appointments—The appointment of two new district managers has been made by the Stewart Motor Corporation, Buffalo, N. Y., maker of the Stewart light delivery truck, E. E. Dennison, covering Illinois, eastern Iowa and Missouri, with headquarters at Chicago, and W. T. Butler covering New York State and northern Pennsylvania, with headquarters at Buffalo.

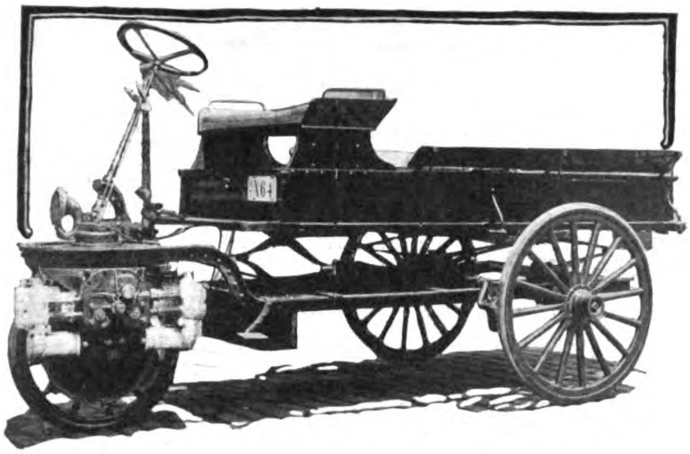
Good Roads in Brazil—A loan netting $650,000 has been floated by the Empreza Autoviaria Paulista, a company which has a government concession for building an automobile road connecting Sao Paulo and Santos, Brazil. The building of this road will mean that an automobile will become a necessity to each one of several thousand coffee planters interested in the vast territory between these two ports.

New Indianapolis Car—It is reported that a new car to be known as the Streamline will be brought out in Indianapolis, Ind., soon by a party of automobile men and capitalists whose names will not be disclosed for the present. The new car, it is understood, will be a 40-horsepower roadster with wire wheel equipment, 110-inch wheelbase, left-hand steer, center control, torpedo body, electric lights, and will sell at $1,300.

Spain's Good Roads—American motorists are invited to visit Spain when they motor abroad, and according to Louis Scatti, of Madrid, who is now visiting Boston, Mass., they will be surprised at the fine roads and the good treatment accorded them. Within the past 12 months some 37,000 miles of highways have been put in fine condition for motoring. An appropriation of approximately $10,000,000 has been made by the government for road improvements.

Whitesides in Indianapolis—In all probability the company being organized by V. F. Whitesides to manufacture a light truck to be known as the Ironsides, will be located in Indianapolis, Ind. Whitesides has announced that he will not consider a proposition to locate in Newcastle, Ind., where he was formerly identified with the Whitesides Commercial Truck Company. The new company will be incorporated and the factory ready for operation early in the new year.

Six-wheel, fourteen-passenger, sight-seeing bus built by the Lake County Automobile Transportation Company, Highland Springs, Cal. The car used is a 7-year-old Columbia



Truck manufactured by the Marsh-Walters Company, Glens Falls, N. Y. It has a two-cylinder opposed horizontal motor, air-cooled, the crankshaft being a unit with the front axle

Steinhauer with Colby—F. P. Steinhauer has become general sales manager of the Colby Motor Company of Mason City, Ia.

Huyette President Q. C. M. C.—P. B. Huyette was recently elected president of the Quaker City Motor Club, Philadelphia, Pa.

Willys Sails—J. N. Willys of the Willys-Overland Company, Toledo, O., will sail for Europe about January 30 for an extended trip.

Everitt Sails—Barney Everitt of the Flanders Motor Company, Detroit, Mich., will sail for Europe this month. He will be gone several months.

Lynch Speedwell Agent—L. V. Lynch has been appointed Western district manager for the Speedwell Motor Car Company, San Francisco, Cal.

Hood with Westcott—Wallace Hood has been appointed sales manager with supervision of advertising of the Westcott Motor Car Company, Richmond, Ind.

Reduction in Price—The Joseph Dixon Crucible Company, Jersey City, N. J., makes the announcement that the selling price of their silica-graphite paint is reduced.

Halliwell's Porto Rico Branch—The Halliwell Company, San Francisco, Cal., is still branching out and recently added a branch in Pòrto Rico. Its representative there will be R. M. Palmer.

Open New Quarters—Luckenbach Brothers, recently appointed Franklin dealers in Allentown, Pa., have opened up temporary headquarters on South Fountain street, near Jackson street.

Paris Joins Reo Truck—R. E. Paris has joined the Reo Truck Company, Lansing, Mich. His addition to the truck company is for the purpose of strengthening the managerial staff of that organization.

Cincinnati Clubs Fire—The Cincinnati, O., Automobile Club, located in the Herschede Building, suffered little from the big fire at the Gibson House recently. The club is now in temporary headquarters.

Express Company Adds Trucks—The American Express Company, Baltimore, Md., has added two more 5-ton General Vehicle trucks to its local fleet, making twenty-five now in use in that city by the company.

Tacoma Will Hold Run—As a secondary automobile feature for the Tacoma, Wash., carnival there will be a 100-mile automobile run over the country roads to be open to every automobile owner who cares to participate.

Texas Trade Good—S. J. Kuqua, vice-president of the Cole Motor Car Company, Indianapolis, Ind., recently returned with glowing reports of the trade outlook in Texas, where a bumper crop of cotton is being harvested.

Hearne Organizing Polo Team—Eddie Hearne, the young Chicago, Ill., driver, has become so interested in the rapidly developing game of automobile polo that he is organizing a team in that city and will practice with it in the winter.

Ford Columbus Branch—For the purpose of establishing a direct factory branch, C. M. Coble, representing the Ford Motor Car Company, Detroit, Mich., in Columbus, O., arrived in that city recently for the purpose of selecting a desirable location to open new salesrooms.

Thirty-five Study Automobile.—The first course in elementary automobile engineering to be given by the University of Missouri, Columbia, Mo., now has thirty-five students enrolled. A $10 fee is charged, and the course does not give credit towards any degree in any department.

Washington Dealers Incorporated—The Automobile Dealers' Association of Washington, D. C., has been incorporated by local automobile representatives for the purpose of conducting the show which will be given at Convention Hall February 3 to 8, 1913. The organization will have complete charge of the exhibition.

Club Shield Impractical—The shield of the Inland Automobile Association, of Spokane, Wash., adopted last spring, has been discarded as impractical. At the recent meeting of the association a new emblem was adopted. This is a thin circular brass plate with the letters of the association embossed on it in black enamel.

Hoosier Club's Minstrel Show—On the evening of December 9, the Hoosier Motor Club gave a minstrel show at the Murat Theater in Indianapolis, Ind., the theater being crowded. At noon, preceding the performance, there was an automobile parade through the downtown streets in which about 200 motor cars participated.

Want Seattle Club in A. A. A.—The question of the Seattle Club, Seattle, Wash., affiliating with the American Automobile Association was brought up and action urged by Ira D. Lundy and others. It was finally referred to the incoming board of trustees with power to act. There is now a paid membership of 678 in the club and the treasury shows a balance of nearly $9,000.

Morris Seattle Club's President—C. L. Morris was elected president of the Automobile Club of Seattle, Seattle, Wash., for the ensuing year at the annual meeting of the club held recently at the Arctic Club. The other officers are: Joseph Blethen, vice-president; John Henry, treasurer; Frank M. Fretwell, secretary; O. B. Williams, R. P. Rice and A. Warren Gould, board of trustees.

Automobile Incorporations

AUTOMOBILES AND PARTS

Asbury Park, N. J.—Cress Automobile Company; capital, $250,000; to do a general automobile business. Incorporators: Louis F. Grice, Harry A White and F. Frank Appleby.

Boston, Mass.—Motor Supply Shop, Inc., capital, $25,000; incorporators: M. V. O'Neil, Walter R. McDaniel.

Buffalo, N. Y.—Buffalo & Interurban Motor Delivery Company, Inc.; capital, $125,000; automobiles and motor trucks. Incorporators: J. G. Berner, W. B. Grandison, C. T. Horton.

Buffalo, N. Y.—Glide Sales Company; capital, $10,000; to deal in automobiles. Incorporators: J. F. Lynch, L. P. Fuhrmann, E. T. Danahy.

Chicago, Ill.—Lakeside Motor Truck Transportation Company; capital, $25,000; to carry on an automobile transportation business. Incorporators: B. P. Dunlap, J. M. Dunlap, E. W. Macavoy.

Chicago, Ill.—Gum Price Motor Truck Company; capital, $100,000; to manufacture automobiles, trucks and supplies. Incorporators: H. E. Rice, Jr., W. C. Haight, Paul Corkell.

Cleveland, O.—Oldsmobile Company; capital, $50,000; to deal in automobiles. Incorporator: P. D. Metzger.

Detroit, Mich.—Kessler Detroit Motor Car Co.; capital, $10,000; to manufacture automobiles and accessories. Incorporators: H. C. Brooks, Jr., Robert McCormick.

Harrisburg, Pa.—Morton Truck & Traction Company; capital, $50,000; to deal in automobiles.

Hudson Falls, N. Y.—Kingsbury Motor Sales Company; capital, $10,000; to deal in automobiles. Incorporators: Leonard Wetsell, E. H. Wells, E. I. Wells.

Indianapolis, Ind.—Premier Agency Company; capital, $30,000; to deal in automobiles. Incorporators: V. C. Vette, D. E. Sherrick, T. H. Adams, W. H. Foreman, J. W. Cowper, H. B. Wilson.

Jersey City, N. J.—Millar Supply Company; capital, $100,000; to do a general automobile business. Incorporators: J. A. Duffy, W. C. Marley, M. E. Thornton.

Kansas City, Mo.—England Brothers Motor Car Company; capital, $2,000. Incorporators: Edward England and E. W. England and others.

Lynn, Mass.—Suffolk Street Garage, Inc.; capital, $5,000. Incorporators: Daniel Lunch, John Buckley, Henry Thomas.

Muskogee, Okla.—Pioneer Motor Company; capital, $5,000. Incorporators: G. S. Waddell, H. G. Butts and M. L. Waddell.

New York City.—Hollister Standard Motor Company, Inc.; capital, $675,000; to construct and sell motor vehicles and supplies. Incorporators: W. H. Langford, Learned White and H. H. Sevier.

New York City.—K. & K. Motor Car Company; capital, $10,000; to deal in automobiles. Incorporators: A. E. Killian, F. B. Killian, L. E. Killian.

New York City.—Schacht Motor Car Company; capital, $60,000; to deal in automobiles. Incorporators: Bela Cukor, H. V. Radonitz, C. J. Terrell.

Ottawa, Can.—The Phoenix Automobile & Trunk Company, Ltd.; capital, $50,000; to manufacture and deal in automobiles, bicycles, motors, engines, conveyances and machinery. Incorporators: J. G. Charrier, S. Bordeleau, Alex. Bordeleau, Napoleon DeGrandmont, Emile Albert Brodeur.

Philadelphia, Pa.—Cole Motor Company; capital, $5,000; to deal in automobiles.

Smith Company Moves—The R. L. & H. H. Smith Company, agents in Boston, Mass., for the Mais truck, has moved from 1002 Commonwealth avenue, in the Back Bay, to 17 India street.

Louisiana's License Tags—No new license tags for 1913 will be issued in New Orleans, La., until January 1. Tags for 1912 will be good until March 1. The 1913 tags are blue with white lettering.

Frisco Franklin Moves—The San Francisco branch of the Franklin Automobile Company, Syracuse, N. Y., has moved from Golden Gave avenue to 1635-45 California street, just east of Van Ness avenue.

Posts 1,100 Miles of Roads—Eleven hundred miles of roads in the arid desert country to the northeast of Los Angeles County, Cal., has been posted recently by the Automobile Club of Southern California.

Bergstrom Rebuilding—The Bergstrom Motor Car Company of Neenah, Wis., is rebuilding its headquarters into a modern garage at a cost of $10,000. A large repair shop will be given room in the remodeled building.

Johns New England Manager—L. B. Johns has been appointed manager of the New England branch of the General Motors Truck Company, with headquarters at the company's office on Boylston street, Boston. Mass.

Toledo to Enforce Ordinance—Director of Public Service J. R. Cowell, Toledo, O., has asked the police department to enforce strictly the city ordinance regulating the size of tires on wagons using improved streets, especially asphalt pavements.

Agencies Consolidated—The American and Marion agencies in Boston, Mass., have been consolidated following a visit to the Hub recently by President J. I. Handley, of the American Motors Company and the Marion Motor Car Company, of Indianapolis, Ind.

Toledo Firm Moves—The Erie Supply Company, Toledo, O., has outgrown its present quarters and will remove in the near future to more spacious rooms at 232-244 Erie street. The concern has dealt exclusively in accessories, but with added space will add a line of cars.

New sales and service building of the Kissel Motor Company in Chicago, Ill. The company claims that the structure, which is now almost completed, is the largest in the world devoted exclusively to the sale and care of automobiles

Lack Cash Lose Sales—Hundreds of sales are lost along Los Angeles, Cal., automobile row because of the inability of the would-be purchaser to pay cash for his car. Other sales are turned down because of the inability of the dealer to carry any considerable amount of paper.

Neuman's Garage—The Neuman Machine Company, 308 East Second street, Davenport, Ia., is to have a new modern two-story garage at Third and Ripley streets. The building will have two entrances, one on Third and one on Ripley street, and will be L-shaped. The garage will cost $10,000.

Four New Bosch Appointments—The Bosch Magneto Company, New York City, has appointed Fry & McGill Motor Supply Company, Denver, Col.; D. A. Schafer & Company, Richmond, Va.; Pence Automobile Company, Minneapolis, Minn., and Johnson-Gewinner Company as its distributors.

Lillian Russell's Car—The Garford Car Company of Elyria, O., recently shipped to Mrs. Lillian Russell Moore, better known to the theatre-going public of America as Lillian Russell, a handsome 4-cylinder town car for winter driving in Pittsburgh, Pa. The exterior finish was of dark blue and white, and special gray whipcord upholstery.

Secure 5-Year Lease—According to Sales Manager Charles Newman the Bunnell Auto Sales Company has secured a 5-year lease on new rooms in the building now being erected at the corner of Madison and Fifteenth streets, Toledo, O. The change will be made about January 1. A large show room, general offices and a service department will be provided.

Want Northerners in Glidden—An effort is being made to induce New Orleans, La., residents who have cottages at Northern summer resorts to make the trip as members of the Glidden tour next spring. There are several hundred persons in New Orleans owning cottages in the North, and the novelty of making the trip through the country has appealed to many.

Findlay Officials Displeased—Some friction has developed at Findlay, O., between the city and county officials relative to the distribution of road funds. The claim is made by city officials that the city has paid into the county treasury more than $1,000,000 and that the county commissioners have expended every dollar outside the city on country roads. An effort is being made to secure a portion of the county funds for street paving.

Starts on Fifth World Tour—Albert Wyatt, San Francisco, Cal., has started on his fifth tour around the world. The former trips were made on trains, steamers, mule and camel back, but the present one will be made in a 1913 30-horsepower Overland car, which will be carried on the decks of steamers and unloaded when a day is to be spent in port. Mr. Wyatt will thus visit Tahiti, New Zealand, Australia, Colombo, Egypt, the Holy Land, Turkey, southern France, Germany, Russia, Siberia, China, Japan, the Philippines and Hawaii.

Graft in Sales—Complaint is being made by New Orleans, La., salesmen that graft is playing an important part in car sales in that city. Commissions are being paid employees who are in daily touch with the prospective purchaser, it is said. With an apparently disinterested person being supplied with information conducive to the sale of a certain kind of car and with an equally good stock of real or imagined weak points in the car of a competitor, sales are being made more difficult for dealers who do not stoop to such methods.

Automobile Incorporations

GARAGES AND ACCESSORIES

Akron, O.—Motor Starting Company; capital, $25,000; to manufacture a new type of automobile starter. Incorporators: R. A. Woods, M. Paul, A. M. Tschantz, E. W. Paul and C. L. Dinsmore.

Barnesville, Minn.—Broadway Garage Company; capital, $25,000. Incorporators: Ernest Leonhardt, Geo. H. Dahm, Gustave W. Seefeldt, James N. Fisch, John A. Cramer and Joseph H. Doltz.

Chicago, Ill.—Storm Shield Manufacturing Company; capital, $100,000; to manufacture automobile accessories. Incorporators: R. E. Wighton, L. E. Street, N. P. Street.

Cincinnati, O.—Northway Motor Company; capital, $600,000; to manufacture automobiles and engines. Incorporators: R. E. Northway, Wm. Pabodie, W. D. Fruste, Ed. E. Decebach and F. B. Enslow.

Cleveland, O.—Marvel Automobile Supply Company; capital, $5,000; to manufacture automobile accessories. Incorporators: J. B. Rosenstein, G. L. Armington, M. L. Rosenstein, S. I. Rose, E. L. Fouts.

Columbus, O.—J. Leukart Company; capital, $30,000; to manufacture mortising machines, etc., machine job work. Incorporators: J. Leukart, K. Leukart, W. J. Leukart, C. M. Leukart and M. T. Leukart.

Detroit, Mich.—The Detroit Auto Heater Company; capital, $2,000.

Gloucester, Mass.—Twin Light Garage Company; capital, $10,000. Incorporators: F. A. Corliss, J. F. Perkins.

Huntington, Minn.—Huntington Auto Transit Co.; capital, $25,000. Incorporators: James M. Hicks, Samuel A. Stemen, John W. Caswell.

Pontiac, Mich.—Pontiac Motor Castings Company; capital, $8,000; to manufacture steel and brass castings. Incorporators: Wm. J. Brown, Peter J. Donnelly and Timothy E. Lyons.

Rochester, N. Y.—Rochester Macandaryba Tire Filler Company; capital, $10,000; to manufacture a tire filler. Incorporators: C. S. Morris, J. S. Crosier, A. C. Olp.

Rockford, Ill.—Schlig Auto Repair Company; capital, $5,000; to conduct automobile and garage business. Incorporators: J. J. White, J. Schlig, Doris White.

Waco, Texas.—Waco Auto Supply Company; capital, $5,000; to sell automobile supplies. Incorporators: W. H. Montz, H. B. Lyne and James Harrison.

Richmond, Ind.—Pilot Car Sales Company; capital, $50,000; to sell automobiles. Incorporators: J. E. Hayes, Arnold Schaer, H. E. Bradford, C. E. Hayes, W. D. Williams, E. F. Goggins, T. F. Williams.

Richwood, O.—Scharf Gearless Motor Car Company; capital, $5,000. Incorporators: Geo. W. Worden, John A. Scharf, W. H. Siples, E. E. Payne, L. J. McCoy.

San Antonio, Texas.—Knight Motor Car Company. Incorporators: H. L. Knight, A. H. Danforth and A. H. Elmore.

Springfield, Mo.—Ozark Motor Company; capital, $5,000. Incorporators: M. R. Swinney, W. W. Tillman and W. C. Swinney.

Toledo, O.—Worthmore Washing Machine Company; capital, $10,000; manufacturing and dealing in washing machines, motors, appliances and supplies. Incorporators: F. M. Sala, A. J. Richie, E. M. Sala, F. A. Carabin, F. N. Alexander.

Toronto, Ont.—Foreman Motor and Machine Company; capital, $40,000; to manufacture engines. Incorporators: G. H. Foreman, W. J. Brown, T. H. Sharp.

Wilmington, Del.—Light Commercial Car Company; capital, $100,000; to deal in motor trucks. Incorporators: H. E. Latter, W. J. Maloney, N. P. Coffin.

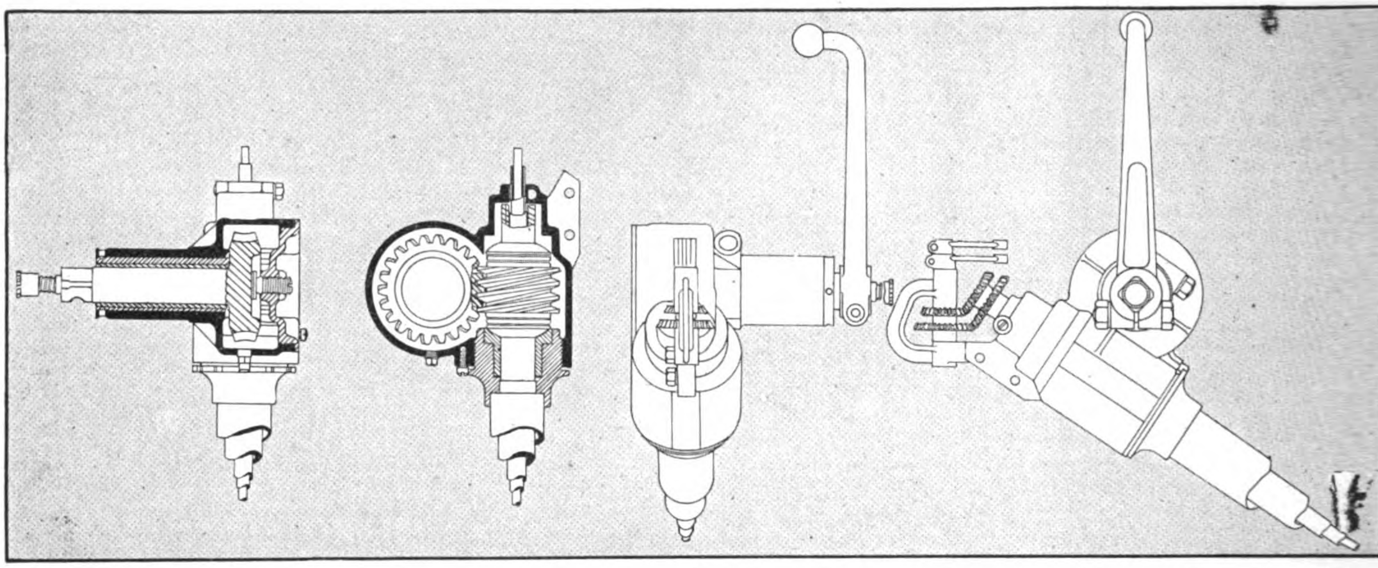


Fig. 1—Mechanical details of the new steering gear made by the Warner Manufacturing Company for heavy touring cars and light commercial vehicles

New Warner Steering Gear and Truck Gearset

Accessibility and Durability the Aims in Construction of New Designs—Gearset Is Integral with the Differential

FEW persons stop to consider what an important part the automobile parts manufacturer plays in the motor car industry as it is conducted today. It is safe to say that at least half of the motor cars manufactured contain constructive parts which were not made by the concern under whose name the cars are marketed. Indeed, many of our well-known makes of cars are entirely, or almost entirely, assembled, as distinguished from being manufactured, in the sense that all the parts are made individually for the car under its own roof.

In spite of this fact that the industry depends as much on the parts manufacturers as it does on the actual builders and makers of automobiles, the manufacturer who gets out these parts, such as steering gears, transmission gearsets, mufflers, tanks, rear and front axles and running gear and frames, is little known. This class of manufacturer in the automobile industry gets very little publicity, preferring to let his product speak through its performance in the car to which it is fitted rather than to make claims for it as a part alone and unidentified as a member of a well built whole.

A representative of The Automobile was given this explanation of the parts maker's stand, when the factory of the Warner Manufacturing Company, Toledo, O., was visited recently. Although a number of excellent parts of new design are being manufactured by this concern, very little has been said about them to the general public.

Among the newer products are those illustrated herewith. Fig. 2 shows a steering gear specially designed for heavy touring cars and light commercial vehicles. The part presents a very simple appearance, all unnecessary features having been eliminated. This gear is of the conventional worm-and-worm-wheel type. The pitch of the teeth is heavy, and the bearing surfaces are long.

The 18-inch wheel is corrugated on the inner side and the length of the steering column from the wheel to the center of the worm is 50 1-8 inches. This steering column has an outside diameter of 2 inches, the rods which connect with the spark and throttle levers and with the steering wheel being contained concentrically within the outer housing of the column, as in most steering gear constructions for the past few seasons.

The lower end of the spark and throttle rods are not housed, thir small bevel gears being open, Fig. 1, so as to be readily accessible. The worm and worm wheel are well housed. The distance between centers of the worm and wheel is 3.125 inches, and the worm has four threads. The worm wheel has twenty-two teeth. From the center of the steering column to the end of the worm wheel bearing is 4.75 inches.

One of the most important considerations with any product of this kind is that for the taking up of wear, and the designers of this new steering gear believe that they have afforded means for the taking up of all wear to which the part is subjected. It is furnished in brass, nickel or black enamel to meet the needs of the car maker of whose machines it is to form a part. The wormshaft is dulled so that lubricant from the grease cup will reach the entire bearings.

Ball thrust bearings are used above and below the worm. The radius arm with ball end is split at the upper end where it fits over the squared end of the worm shaft; the use of the square permits of using the four quarter of the worm wheel to engage with the worm in case of wear. This affords an adjustment feature.

Another new product of the Warner factory is the 5-ton truck integral gearset and differential unit shown in section in Fig. 3. It provides four speeds, with direct on third. The construction is substantial. The entire transmission is mounted on annular ball bearings, while the driving pinion and differential are carried on Timken roller bearings. The chrome vanadium steel gears have five pitch and a 1.5-inch face and are mounted on very large hardened and ground broaches on a splined shaft.

In driving on fourth speed the increase over the direct drive is 21 per cent. The revolutions of the two gearshafts, taking the main driveshaft B as the reference shaft, are given by the following table:

Speeds	Revolutions of Shaft "A"	Revolutions of Shaft "A"
Reverse	4.320	1
First	3.810	1
Second	1.750	1
Third	1.000	1
Fourth	.828	1

The housing is heavy, having a thickness of .4375 inch and being of gray iron. Heavy arms pass back for attachment to a cross-member of the chassis frame back of the jackshaft. It will be noticed that, while the gearset and differential are integral, yet they are separated from each other by a well D, cast integrally with the gearbox. This wall or partition also serves as a rear bearing for the main driveshaft as well as for the countershafts.

The master shaft A of the set is short and stout and has formed integrally with it the master gear A1 which drives to the countershaft. Within this gear is a large annular ball bearing on which the forward end of the splined mainshaft is carried, this facilitating the lubrication at this point. The short shaft A is supported on two ball bearings insuring permanent alignment and quiet meshing of master gear A1 with its countershaft gear.

Particular care has been taken at the forward end of the mainshaft to prevent oil leakage by a stuffing gland secured by a cap. This cap threading with the bearing cap and being locked by set screw K1 at any point. Similar anti-oil leak precautions have been taken where the jackshafts enter the differential housing at K2 and K3. End plates P covering the countershaft bearings preclude oil leakage at these points. Thrust between the pinion and differential is cared for by the three Timken bearings, one in front of the pinion and the others carrying the differential. In addition is a ball thrust T to resist any thrust on the splined shaft in the direction of the differential.

These parts are the result of concentration on these particular members of the automobile chassis, and they have been developed to a high state of efficiency through such concentration.

There are those who argue against the assembled car, stating that it is not the equal of the machine whose parts are all made individually designed to be assembled in connection with other individually designed parts. Yet the assembled car in performance has proven itself the equal of the other under many tests. If a judicious selection of parts is made, there is no reason why the assembled car should not be equally serviceable. The designer of this car must be just as expert as he who designs every part of his car's makeup. The former must know how to intelligently and consistently combine parts made in different factories so that the whole will be mechanically correct.

Benzol as Automobile Fuel

Syracuse, N. Y., Dec. 16—The Semet-Solvay Company, of this city, has prepared to introduce benzol, a by-product of coal tar oil, as a substitute for gasoline for automobiles. Though known to Europeans, and in use to some extent over there for 4 years, it was only introduced here a few months ago. It is obtained from coke retort ovens. As the only refining plant so far is in Solvay, near Syracuse, the automobile owners of this city have the first chance to experiment with the new propelling medium.

It is a water white liquid of a fairly high specific gravity and bears the same relation to coal that gasoline does to petroleum. Like the common motor fuel, the principal expense is the refining. Whether benzol will become eventually as popular among motorists remains to be seen. It is claimed that the demand for gasoline is so great that some dealers have taken to mixing kerosene with it to supply the market.

Motorists have been hoping for an effective substitute and the Syracuse experiments will be watched with a great deal of interest. It is claimed that benzol will not cause carbon deposits, but will on the contrary remove all such coatings. If this should prove true it would eliminate the necessity of grinding valves and frequently changing spark-plugs. It is also claimed that benzol will give 30 per cent. more mileage than the present grade of gasoline and contains certain valuable lubricating qualities.

Benzol has the chemical formula C_6H_6, meaning that each molecule of it is composed of six atoms of carbon and the same number of hydrogen atoms. Pure benzol, which however only constitutes about .5 per cent. of the coal tar, boils at about 180 degrees Fahrenheit and is chemically uniform throughout. It stands to reason, however, that the small percentage of it found in the coal tar invites adulteration, and, as a matter of fact, commercial benzol generally contains some heavier derivatives of benzol, such as toluol, xylol, etc. Their effect upon the benzol proper is that they raise its specific gravity and its boiling temperature.

Novel Air-Operated Self-Starter; Carbonox Decarbonizer; Motometer Radiator Thermometer; Simplex Arrow Tread; New Radiator Cover; Electrene Fire-Extinguishing Gun; Capstan Block; Tire Preserver

Compton Pneumatic Self-Starter

A NEW self-starter is being manufactured by its inventor, Melving D. Compton, 154 Nassau street, New York City. This starter consists of a reciprocating, compressed-air motor to which air is supplied from a tank filled by way of an explosion valve, the latter being fitted into the head of one of the engine cylinders. The front and rear view of the starter proper is shown in Fig. 4, showing the mechanism inclosed in a metal casing, the motor part which serves as a moving agent, in a cylindrical case, and the transmitting gears which act directly upon the crankshaft, in a square box. In Fig. 5 the construction of the starter as well as the arrangements of the principal operating units is illustrated. The air compressed by the explosion valve is stored in a tank which is placed on the running board or in any other suitable position, and a gauge G on the dashboard shows at all times the pressure of air in the tank. The handle C controls the valve which opens the way from the tank to the starter S. The latter is connected to the crankshaft C1 in any desired manner, either in place of the starting crank or next to the flywheel, depending upon the construction of the car on which the starter is used. By means of two air inlets governed by a system of valves, air is alternately admitted at either end of the starter-motor cylinder, thereby reciprocating the piston P in the same. A connecting rod attached to the piston carries at its other end a flexible crosshead to which two oppositely toothed racks are attached, which alternately engage the pinion positioned between them, which is mounted on the crankshaft. Thereby the reciprocating motion of the piston is converted into a continuous, rotary movement, the effect of which is the starting of the engine. As soon as the latter moves by its own power a system of pawls carried by pinion and rack throws the latter out of engagement with the former, and incidentally, the flow of air into the starter cylinder is shut off by means of a specially constructed mechanism not shown in the illustration.

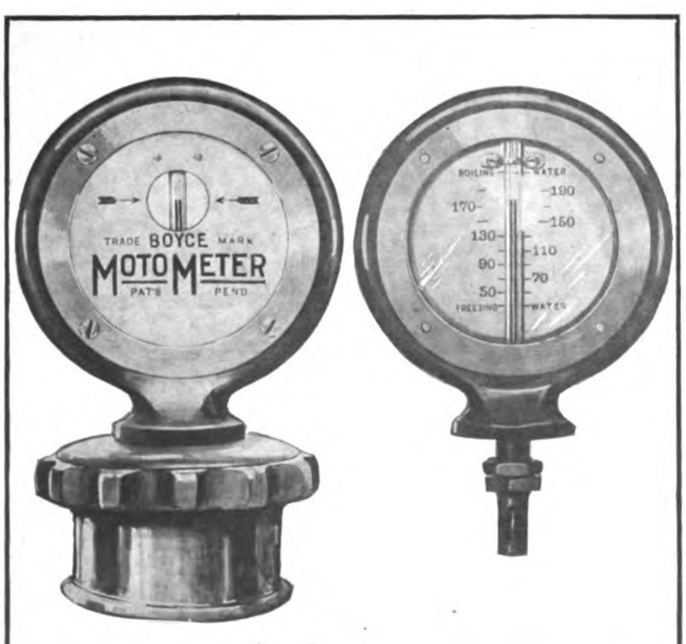

Fig. 1—Motometer cooling water gauge for radiator

Carbonox Chemical Deposit Remover

One of the latest carbon deposit removers on the market is the product of the Northwestern Chemical Company, Marietta, O., which is called Carbonox and sells in cans of various sizes, fitted with a combination cap and spout. Carbonox is a compound which loosens the carbon deposited on the cylinder walls by dissolving the oily material which binds it thereto, after which it keeps the carbon in suspension and makes its combustion possible. It is a mixture of various constituents, some of which are very volatile. To remove the deposits from the cylinders by means of Carbonox about .5 pint is used for four cylinders. The liquid is poured into the combustion chambers through the spark-plug holes, and if this is done while the engine is hot the spark-plugs should be replaced immediately to prevent evaporation of the remover; whereas, if the engine is cold it is good practice to soak the plugs in a small pan filled with Carbonox to remove oil and carbon from the sparking points. After this is done the plugs are put back in their places, and the engine is turned over a few times, with the ignition system shut off. After 20 minutes the engine is started and run until the exhaust is clear, which indicates that all the carbon suspended in the remover fluid has been burned. As soon as this is the case, a little lubricating oil should be squirted into every cylinder through the priming cup.

Motometer Cooling Water Gauge

There are few automobilists today who are not familiar with the detrimental effects caused by overheating radiators, which state of things not only indicates that something vital is amiss with one or with several parts of the motor system, but is in every case accompanied by a reduction of operating efficiency of the motor. In order to enable car drivers and owners to see from the inside of the car whether the radiator water is maintained at the right temperature or not, the Motometer has been devised, being the invention of a former racing driver and made by the Motometer Company, Inc., 1784 Broadway, New York City. The Motometer, Fig. 1, is a specially constructed thermometer which is fitted with a stem projecting into the interior of the radiator and indicating the temperature obtaining there by the use of a column of red liquid confined in a conventional type of thermometer tube. The latter is fitted with a bulb at its lower end and is closed hermetically at its upper end, there being a vacuum above the surface of the indi-

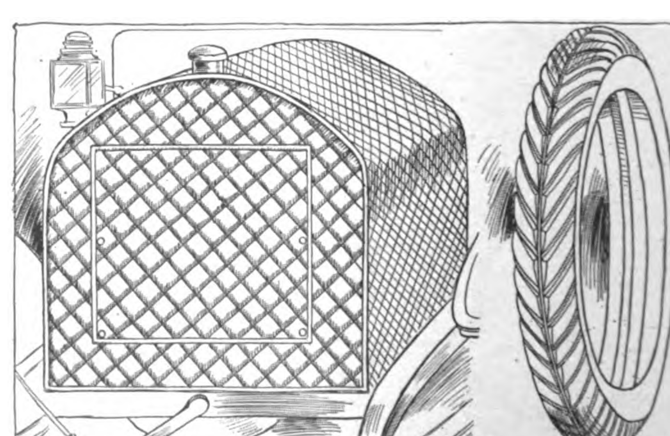

Fig. 2—New radiator cover Fig. 3—Simplex tire

cating fluid; the latter is a specially prepared chemical compound operating with equal exactness at all temperatures between the freezing and boiling points of water. The thermometer tube is placed in front of a silver-faced dial held between two crystal glass plates, and is therefore clearly visible in daytime, while at night its visibleness is insured through the effect of a hole in the dial, through which the light of the headlights may be seen. The correct level for the thermometer fluid, indicating the right temperature of the motor-cooling water, is marked clearly in the middle of the dial, as is the boiling point, while too low a temperature is indicated by the fluid sinking below the freezing level on the dial. As Fig. 1 shows, the Motometer has the shape of a watch and the stem which protrudes into the radiator through a .375-inch hole in the cap is so short as to remain above the surface of the water in the radiator at all times; the temperature measured is that of the air above the water. Consequently, if steam is developed in the interior of the cooling system, the Motometer immediately indicates 212 degrees Fahrenheit, thereby warning the driver that something is at fault, with the cooling system.

Simplex Long-Life Rubber Tire

A tire design which promises longevity of outer casings is the Simplex, Fig. 3, of the U. S. Supply Company, 1779 Broadway, New York City, being manufactured by the Simplex Rubber Company, of the same city. This casing is built up of eight plies of cotton fabric thoroughly frictioned together with rubber. This part of the construction is rather conventional, but the unusual element comes in with the tread design shown in Fig. 3. The surface is formed with a number of laterally extending ribs, flowing back from a central ring formed in relief on the outer surface of the tread in the same manner as the aftershafts are arranged on the quill of a feather. The height of the central and lateral projections is .625 inch, which portion of the tread is formed of live rubber. This construction has the double effect of giving an anti-skidding action to the tire running forward on the ground and incidentally protecting the top layers of the casing rubber as well as the fabric underneath them.

Winter Cover for Radiators

The Mutual Accessories Company, 1937 Broadway, New York City, markets a radiator cover for preventing the freezing of the cooling water in winter weather. This cover is designed to be fitted over the motor bonnet and radiator and to remain there throughout the cold season, the front being so constructed that a smaller or greater part of the radiator may be exposed to the cooling influence of the wind striking the traveling car. The cover, Fig. 2, is made of a material which is a poor conductor of heat, and its outside is finished like leather, so that it can but improve the appearance of the car and give it an exterior in harmony with the conditions obtaining at this part of the year. An opening is formed in the top of the front portion to permit of the radiator cap protruding through the cover, so that refilling is possible without any difficulty whatever. The front arrangement is clearly shown in Fig. 2, the flap which covers the radiator being capable of attaching to the bottom of the opening over which it fits; it is secured by snap fasteners formed as buttons. If partial cooling of the radiator surface is desired, it is merely necessary to unbutton the fasteners and attach the lower ones in the height of the middle of the opening, or they may be secured to the top line of the cover to give still more cooling surface. This accessory is made in three sizes, namely, for cars of more than 30 horsepower, for cars of less than that power, and for Ford cars especially.

Mutty Numotor Top Fabrics

The L. J. Mutty Company, 91 Federal street, Boston, Mass., is clear, which indicates that all the carbon suspended in the called Numotor, which is made of high-grade cotton yarns dyed in the fiber. The material is made into a double-texture fabric with an interlining of high-grade Para rubber, where the material is made for tops, while for seats a single-texture fabric is used. It is also to be had with a leather coating and in this grade is referred to as Numotor leather. Some very pretty color schemes are being used by the Mutty company, being obtained by the use of varied-color yarns woven into the material.

Electrene Fire Extinguisher

The Electrene Company, Whitehall Building, New York City, is the manufacturer of the latest development in the line of fire-extinguishing guns. The Electrene gun is filled with a chemical positively extinguishing fires of any origin and feeding upon any kind of fuel, the pumping medium being compressed air which is stored in one part of the extinguisher, while in the other half, which is equipped with the nozzle spout, the extinguishing fluid is contained. A Schrader valve is used for ad-

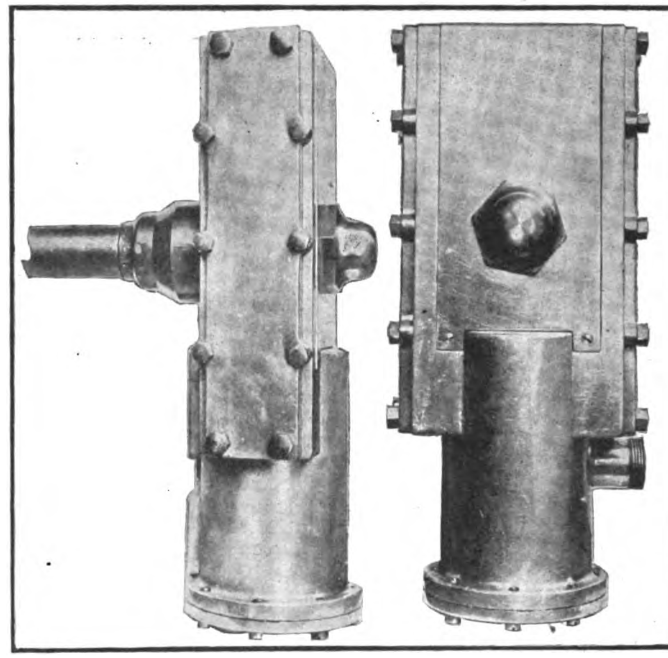

Fig. 4—Front and rear view of Compton air starter

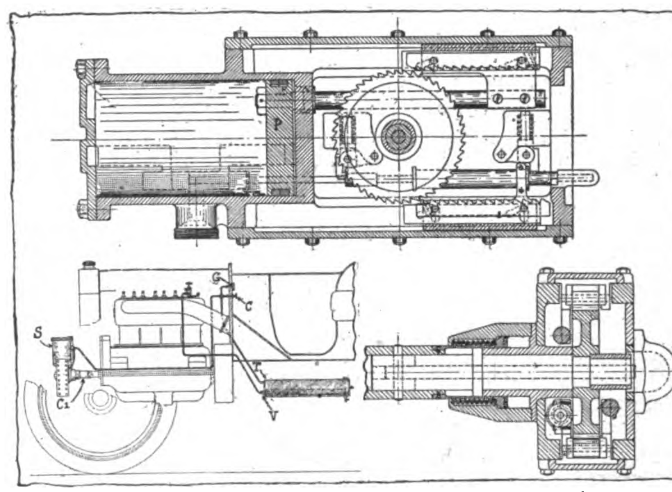

Fig. 5—Arrangement of starter units and part views

mitting the compressed air into the space where the chemical is carried, and to actuate the valve a rotatable handle is used, the latter being fitted to the top of the extinguisher, while the nozzle is provided in its lower end. The Electrene fire gun is furnished in any one of three sizes, the latter being 2 quarts, 1 quart and .5 quart respectively.

Laurent-Cherry Capstan Block

Capstan blocks designed for emergencies in which automobiles require to be hauled out of ditches, mudholes and so forth, are made by the Monitor Engineering Company, 1001 Chestnut street, Philadelphia, Pa. Every set consists of 50 feet of rope and of two blocks, one of which is constructed with a pawl-and-ratchet mechanism permitting of working it as a capstan. If a car is to be hauled out of a place which it cannot leave under its own power, the ordinary block is secured to a tree or other stationary object, while the block which contains the ratchet mechanism is hooked over the front axle of the car, the mechanism then being worked and the rope pulled in, whereby the car is brought out of its awkward position. The set takes very little space and may be carried in the toolbox, being a handy accessory which in time must prove of value to everyone who appreciates complete touring equipment.

Rubberset Tire Preserver

The Rubberset Company, Newark, N. J., manufactures a solution for coating outer casings with white paint, thereby improving their appearance. The paint particles are suspended in a solution containing some rubber-like substance which fills up small wounds in the tread and protects them from decay.

INTERNAL-Combustion Motor—In which the cylinder forms a pump and an explosion chamber.

This invention is illustrated in Fig. 1. Each working cylinder of the engine is shaped to form an explosion chamber, E, and a pump cylinder, P, within the same. A pump piston, Q, works in the cylinder, P; the latter is in communication with the inlet manifold, so that mixture may be taken into it and compressed into it, being transferred through a valve-controlled port in the piston Q into the explosion space E. There the mixture is burned and actuates a working piston, Q1, which bears on the crankshaft, and to which the end of the connecting rod of piston Q is secured. Piston Q1 has a pair of cylindrical walls spaced from one another so as to provide an oil passageway; the inner wall is formed with ducts, D, for conveying the oil to the exterior of the pump cylinder, oil being delivered to the ducts by way of an inclined flange, F.

No. 1,046,704—to Samuel Ybarra, St. Louis, Mo. Granted December 10, 1912; filed January 26, 1912.

Automobile Chassis Design—Including a flexible suspension.

This patent refers to a chassis, Fig. 2, in which the rear axle R is surrounded by a casing rigidly connected to one end of a reach, R1, the other end of which is yieldingly connected to the frame of the chassis. A power plant is adjustably supported by the front end of R1 and a transmission is in position between axle and power plant.

No. 1,046,681—to Morris S. Towson, Cleveland, O. Granted December 10, 1912; filed April 1, 1909.

Hydrocarbon-Fuel Carbureter—Being of the capillary vaporization type.

Fig. 3 shows the capillary carbureter referred to in this patent, in which vaporization of the gasoline is effected by the surface action of a wicklike substance through which the fuel passes. The carbureter casing is divided into an upper and lower compartment, U and L, respectively. The upper compartment is designed with a carbureting air inlet A and the lower compartment with a mixture outlet O. Fuel is supplied by way of the pipe S which leads into L, while air passes through A and U and thence through a passage into L. Fuel passes through the float-controlled valve V into the float-chamber F, whence it is fed through the material surrounding F to the surfaces of the capillary material filling L.

No. 1,046,653—to John Ruthven, Detroit, Mich. Granted December 10, 1912; filed January 25, 1912.

Tire Clincher-Ring Lock—Comprising a snap ring in combination with the rim, which holds the latter in place.

This patent refers to a clincher-carrying device, as shown in Fig. 5, which consists of a rim, R, carrying the tire and a removable clincher ring, C, slidably mounted on R and engaging one side of the tire. A snap-ring, S, is seated in the rim R and is adapted to restrain C from moving outwardly; a pin, P, movably mounted in the rim automatically locks behind the clincher ring when the latter is forced inward.

No. 1,046,855—to Peter Recconi, San Francisco, Cal. Granted December 10, 1912; filed October 21, 1911.

Force-Feed Lubricator—In which a horizontal lever actuates the pumping plunger.

The force-feed lubricator shown in Fig. 6 composes a reservoir which has a pump formed in one of its sides; a movable member, M, is adapted to reciprocate in the pump cylinder, being fixed to the end, E, of a lever, the other end E1 of which extends between guide-rods and is movable between the fixed fulcrum F and the adjusting-fulcrum screw A, so that the stroke of the plunger M may be varied. A cross-pin P on E1 coacts with guide-rods G and prevents casual displacement of the lever.

No. 1,046,563—to John F. Dake, Rochester, N. Y. Granted December 10, 1912; filed October 3, 1910.

Tire-Fastening Device—Including an expanding and a contracting ring for holding the tire tightly in place.

The tire-fastening device described in this patent works in combination with a rim, R, Fig. 4, and consists of an expansible clamping ring, E, which engages R at each side beneath the tire. A contractible ring, C, engages the outer sides of the tire between the rim and the ring E; the two pairs of rings mutually tend to draw the tire tightly upon the wheel, while a guard ring, G, holds it in place.

No. 1,046,629—to William Robert Morrison, Chicago, Ill. Granted December 10, 1912; filed April 17, 1911.

Motor Lubricating System—In which the flywheel casing serves as an oil passage between transmission and crankcase.

This patent refers to an oiling system in which both the crankcase and the transmission casing are formed in communication with the flywheel casing. This is done in such a manner that the overflow of oil from the crankcase as well as from the transmission passes into the flywheel casing and provision is made for the transfer of surplus transmission oil passing into the crankcase

No. 1,046,524—to Charles E. Wiffler, Detroit, Mich. Granted December 10, 1912; filed January 17, 1910.

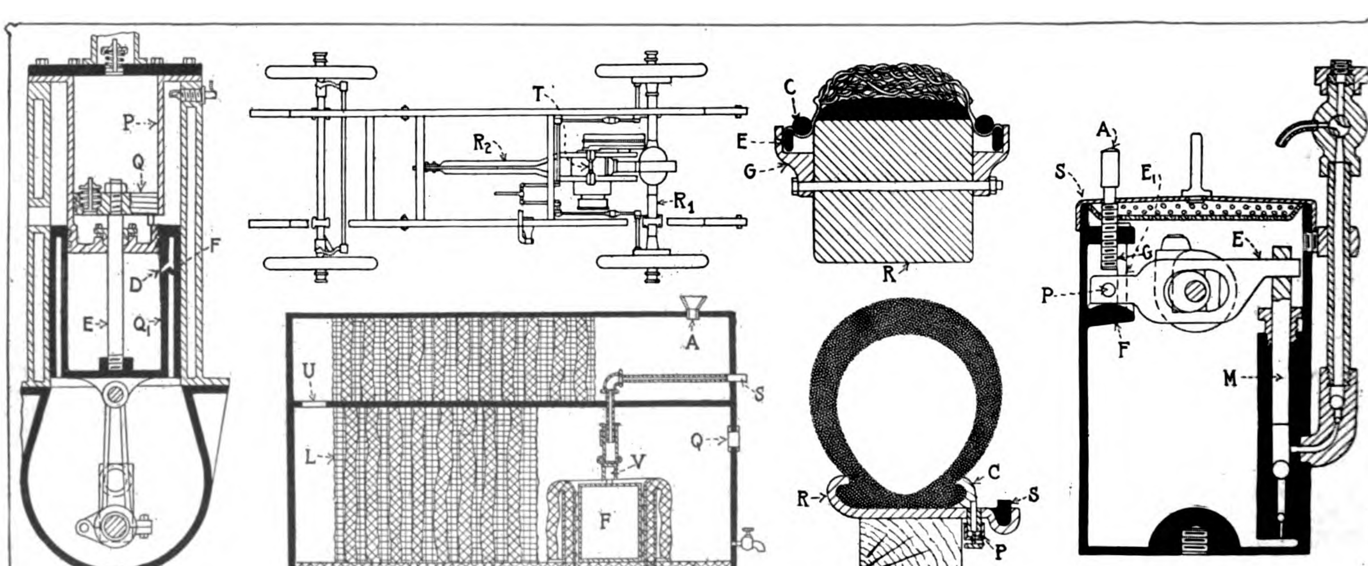

Fig. 1—Ybarra motor. Fig. 2—Towson chassis. Fig. 3—Ruthven carbureter. Fig. 4—Morrison tire-fastening device. Fig. 5—Recconi rim lock. Fig. 6—Dake lubricator

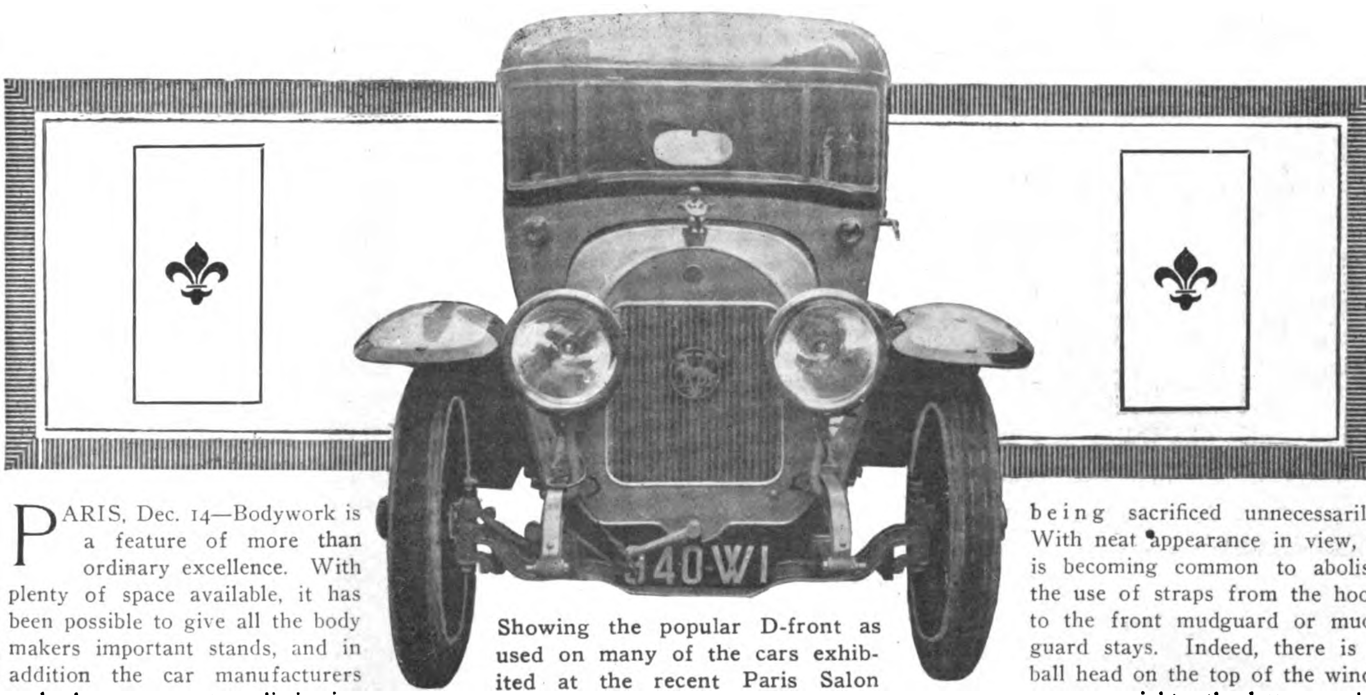
VOL. XXVII NEW YORK—THURSDAY, DECEMBER 26, 1912—CHICAGO NO. 26

The AUTOMOBILE

Bodies Big Feature at Paris Salon

Streamline Bodies Are All the Rage—Clean Outlines and Neat Appearance with Greater Comfort, Accessibility and Baggage-Carrying Capacity—Improved Disposition of Accessories

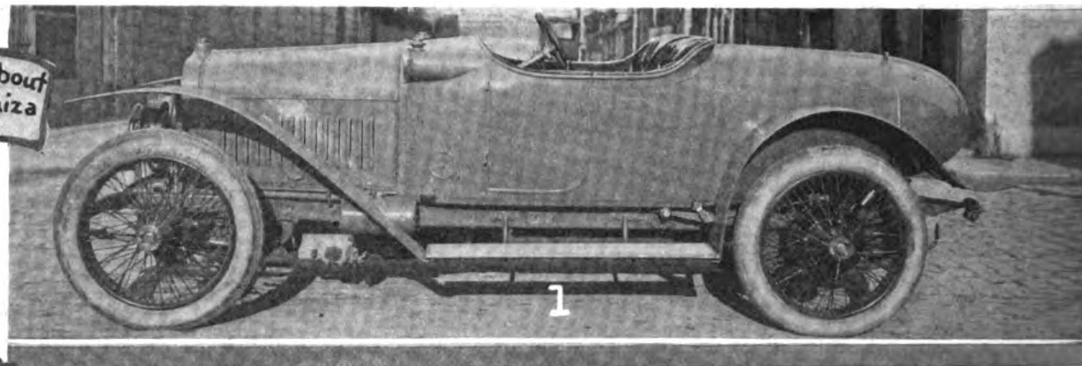


Showing the popular D-front as used on many of the cars exhibited at the recent Paris Salon

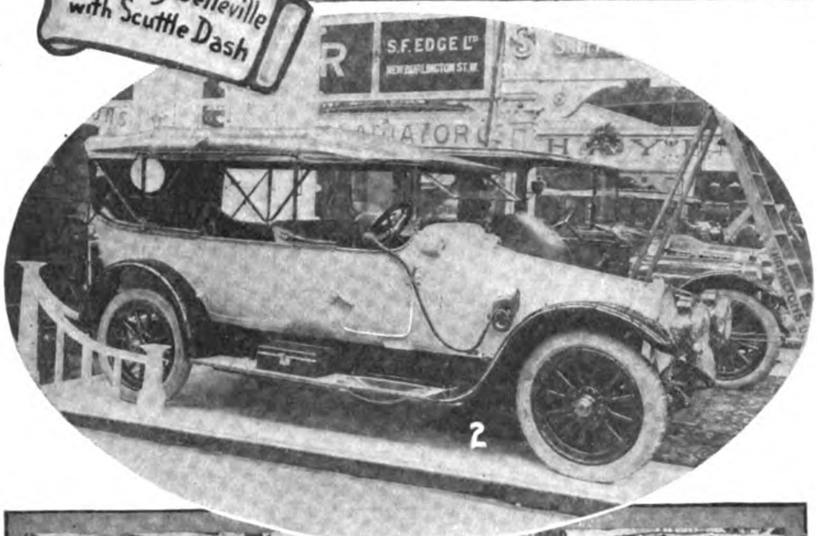
PARIS, Dec. 14—Bodywork is a feature of more than ordinary excellence. With plenty of space available, it has been possible to give all the body makers important stands, and in addition the car manufacturers each show one or two distinctive types of bodies, side by side with their chassis. This makes it possible for the Paris salon to be the finest display of body work in the world. Whatever the type, whether it be a little runabout or a heavy limousine, the main desire is to get unbroken lines so as to offer a perfectly boat-shaped streamline body. All added accessories are being eliminated as far as possible: levers are brought inside the body, lamps are inserted in the scuttle dash or merged into the front mudguards, the horn is made as inconspicuous as possible, tool boxes form a part of the running boards, and not a projection on them, and in no case is there a break at the dashboard, the line being unbroken from the radiator to the rounded-off rear panel. A couple of seasons ago the streamline designs were in the hands of speed maniacs who were willing to make great sacrifices of comfort and space in order to have clean, unbroken lines. There has been progress since then, and while every effort is being made to get unbroken lines, comfort, accessibility and luggage-carrying capacity is not being sacrificed unnecessarily. With neat appearance in view, it is becoming common to abolish the use of straps from the hood to the front mudguard or mudguard stays. Indeed, there is a ball head on the top of the windscreen uprights, the latter receiving a socket on the front bow of the hood and the two being locked together by a winged nut. It is just as effective as straps and considerably neater. On two-seaters there is the advantage that tops can be put up by this method without getting out of the car. There is a strong tendency, particularly on touring cars, to enamel all the metal work in the color scheme of the car instead of having it polished. In some cases this has been extended to the lamps, but this is not general.

In the accompanying illustrations of novel body types are included some constructions shown at Olympia which are of interest in connection with those exhibited at the salon.

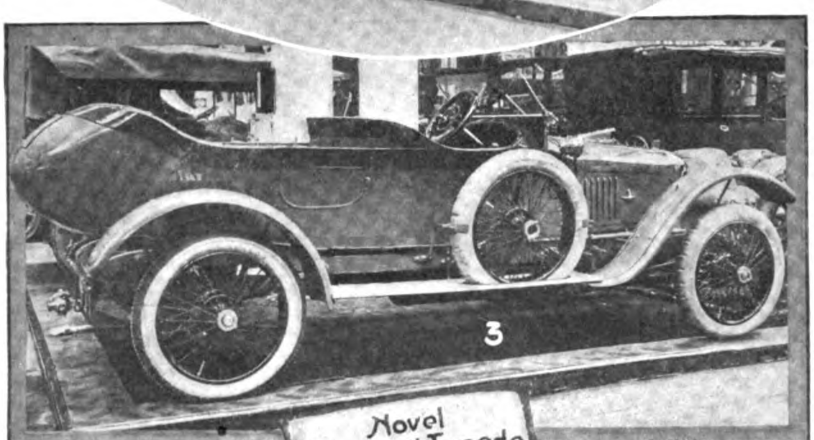
In a few cases an attempt has been made to avoid the abrupt break of the windscreen in order to harmonize with the stream lines of the body. On an open car this is really a difficult matter without making the screen a fixture. On a Martini car a very good effect was obtained by making the screen V-shaped, thus giving better protection to the occupants, offering less



Torpedo Runabout on Hispano-Suiza



Delaunay Belleville with Scuttle Dash



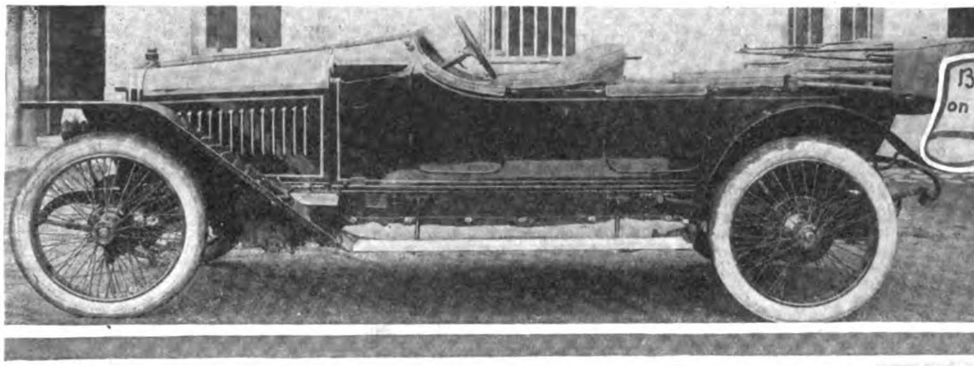
Novel Vauxhall Torpedo

resistance and making it possible to hinge the two portions of the screen in any desired position. Provision for baggage becomes a difficult problem when it is sought to retain stream lines, and there is also the problem of stowing away spare tires and wheels so as not to disturb the harmony of the car. On a D. S. P. L. there was a very neat arrangement of a circular locker at the rear of the car, the diameter of which was slightly less than that of the demountable rims. Thus two rims could be placed on the projecting locker, and as this compartment had a bulging door, the general effect was that of an egg-shaped torpedo. The circular locker in itself gave considerable space, but this was further increased by extending the storage space under the rear seats, with admission, of course, from the rear. There were several cases in which a large luggage compartment or tire compartment was built in the rear panel, this panel being hinged to give admission.

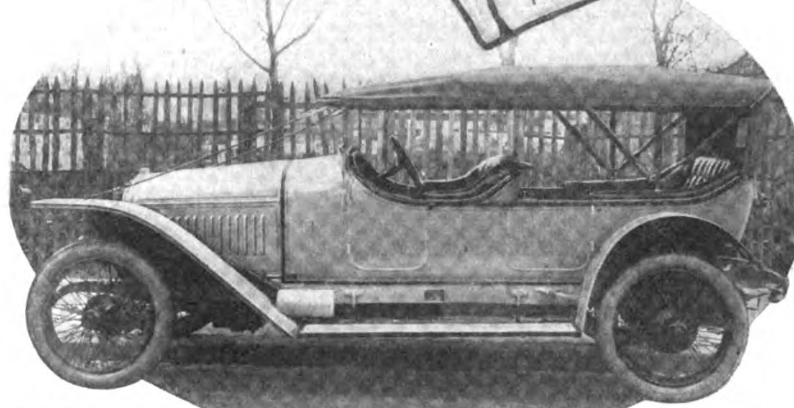
The two extremes of cars—open, full touring models or closed berlines or saloon cars—are in favor in France at the present time. All-weather types find comparatively little favor. The stream line D-fronted berline is a very strong feature. It is nearly always made with a dome roof, the sides rounded off into the back and the front, no dashboard, and generally two entrances on the left-hand side and one on the right-hand side. Alin & Liautard has made a specialty of this type of body and has some very attractive models on

Tub Lamp Under Hispano-Suiza Mud guard

Lorraine-Dietrich Torpedo Touring



Body by Keloch on Hispano-Suiza



Torpedo by Alin & Liautard on Hispano-Suiza

view. One of the most interesting is what is known as the "egg body" built on a Gregoire chassis. It is a saloon car with rounded roof, surmounted with a second roof, as on trolley cars, but with all the angles rounded off. The front of the body is D-shaped, being all glass, and the whole of the roof is of glass. The rear of the body is egg-shaped, but all the space at this portion of the car has been made use of for luggage and spares. Through a door at the rear fitted with hidden hinges a detachable wire wheel can be pushed into a special compartment under the rear seats. Below this is a locker of sufficient size for all the tools and spares necessary on a car, and above the tire cupboard is a larger compartment suitable for luggage. Although there are three doors, each with a pair of hinges and a lock, the work is so neatly done that it is only on close examination that the joints are noticed. In the two rear corners of the car, above the seats, are cabinet work cupboards for small articles. The gasoline tank is carried in the scuttle dash.

One of the novelties of the body department of the show is a new type of detachable set for which Lamplugh & Company, of Paris, have secured a patent. A shell body is built, lined with leather or other suitable material and merely left with a couple of low platforms in place of seats. The seats and the backs are made independently, the former being laid on a hinged frame so that they can be inclined as desired and are received on a central stud working on a worm gear by

New York Bar Outlines New Patent Law

Responding to Queries of Taft's Commission on Economy and Efficiency, Gotham Association Frames Suggestions That Form Basis of Report Just Made to Congress—More Revenue and Less Wasted Time and Money Main Points

REPORTING to the President's Commission on Economy and Efficiency, the New York County Lawyers' Association has submitted an outline of patent reform legislation which has just been placed before Congress.

The New York report was one of a numerous series, and upon it and similar information the final draft was based.

In preparing the document the commission submitted a series of twenty-one questions covering the main points in present practice about which question had been raised. These questions and the answers of the New York lawyers are as follows:

1—Do you consider that abolishing one appeal in the Patent Office would be beneficial? Answer: Yes.

At present two appeals may be taken in the Patent Office before recourse is had to the courts.

2—If so, do you favor having one appeal from the primary examiner to the board of appeals, consisting of the highest officials in the office, such board to consist of five or six members, three to be a quorum? Answer: No.

3—If you think it advisable to continue the present system of two appeals within the office, and do not favor the board of five or six to hear appeals from the primary examiner, what procedure do you think best" Answer: It is recommended that the board shall consist of six properly qualified members to be appointed by the President, of whom three shall constitute a quorum.

Would Eliminate One Appeal in Patent Office

4—What changes, if any, do you think should be made in the procedure in interference cases?

Answer: That the present procedure in applications to dissolve for non-patentability, non-interference in fact, or imperativeness be altered so as to permit such questions to be brought up on due notice, at final hearing, with or without prior motion.

That Section 4906 of the U. S. Revised Statutes be amended to definitely authorize the assurance of subpoenas daces tecum in contested cases pending in the United States Patent Office.

That the Commissioner of Patents be given power for good cause shown to refer the issue of priority to a referee for report.

That there be but one hearing on the merits on the Patent Office and that by the proposed board.

5—Should interference cases be eliminated from the Patent Office by a change in the law, and the question settled in the courts after the patent issues?

Answer: No; for the reason, among others, that it would not be fair to the two patentees to have the terms of their patents running while they are held in interference. Nor is your committee prepared to recommend favorably the suggestion that the interferences be prepared in the Patent Office and transfrred to the courts for trials before patent issues—at least until the untried new equity rules have been fully tested and found wholly satisfactory.

6—Should the decision of the Patent Office on the question of priority of invention be made by law subject to review only on the appeal to the Court of Appeals of the District of Columbia? Answer: No.

7—Do you favor the bill pending in Congress which requires that an application for patent shall be prosecuted within six months after any action by the Patent Office, instead of within one year, as at present?

Answer: Yes; with discretionary power in the Commissioner of Patents to extend the time for a further period not exceeding six months on good cause shown.

8—Do you favor making the life of a patent 19 years from date of filing application? Answer: Yes; subject to the provisions of the Oldfield bill. These provisions add the time spent in interferences to the statutory term.

9—Do you favor a change in procedure so that the decision of the primary examiner to allow a patent to issue may be reviewed by the board of examiners in chief, or other board of appeals that may be created in the office, when such a review may be ordered by the Commissioner of Patents? Do you favor any plan for review? Answer: No.

10—What change, if any, in Patent Office procedure is needed to reduce the scope of patentability? Answer: None.

11—Do you favor the enactment of the bill now pending in Congress for the amendment of Section 4889 of the Revised Statutes, to require that there be filed with the application for patent, in addition to the drawing, two photographic copies of such drawing?

Answer: Yes; if two photo copies filed within 30 days after the filing of the application will be compliance with the requirements.

12—Do you favor the passage of the bill now pending in Congress to legalize the assurance of certificates of correction in patents? Answer: Yes.

13—State what change, if any, is advisable in reference to the appeal now allowed from the Patent Office to the Court of Appeals of the District of Columbia.

Answer: Eliminate the appeal in *ex parte* cases, retaining the same in interference proceedings. The construction which has been put on the Statutes by the Courts, requiring an applicant to appeal to the Court of Appeals, D. C., before he can file a bill in equity works a hardship. Moreover, the Court of Appeals, D. C., is not well qualified to decide a question of patentability on the Patent Office record of an *ex parte* case. By bill in equity that question could be speedily and intelligently tried under the new equity rules in a Federal court, upon evidence submitted. We therefore recommend an addition to the Act of March 3, 1897, to the effect, "Nothing herein is to be construed as limiting the right of an applicant to whom a patent has been refused by the Commissioner of Patents, to file bill in equity under Section 4915, without first taking an appeal to the Court of Appeals, D. C.

Strongly Urges Better Pay and Points Way

14—To what extent should the decision on such appeal operate as a final adjudication of patentability? Answer: To no extent.

15—Do you consider it necessary to the improvement of the efficiency of the Patent Office that the salaries paid to the higher officials and to the examining force be increased?

Answer: Yes; because the present salaries are inadequate to the services rendered and present-day living expenses.

16—Do you consider it necessary that the number of examiners be increased, particularly with reference to the work of reclassifying patents and digest of publications and the providing of every facility to simplify and make more accurate the search?

Answer: Yes; especially that the number of examiners be increased. Your committee has been advised by Assistant Commissioner Billings that the number of patent applications this year is now about 5000 more than last year. The number of examiners must be increased to keep pace with the increase of business.

17—What changes, if any, should be made in the official gazette and other publications; and wherein are the methods of handling publications, including copies of patents, subject to criticism?

Answer: That all claims of patents, instead of only the first five, be printed in the official gazette, and that there be a return to the former style of indexing both in the annual indexes and in the weekly numbers of the official gazette, except that such indexes shall omit citations to the volume and page of official gazettes and the volume and page of monthly bound numbers. Also, that the former practice be returned to charging 3 cents per copy where a sub-class is ordered.

18—Should the bills affecting the patent law on which hearings are held before the patent committees of Congress be published in the official gazette? Answer: Yes.

19—What changes, if any, do you think should be made in the application fee and the final fee?

Answer: Fix $20 as the filing fee and $15 as the final fee on applications other than design applications; provided the increased annual revenue thus provided, together with the annual surplus (in all about $225,000) be appropriated to the increase of salaries of the higher officials of the Patent Office. In 1911 there were over 32,000 more regular applications filed than issued. The increase of $5 in the filing fees on those cases would thus give a year's revenue increase of $160,000. In 1911 the surplus of income over expenses was $65,000. The total would thus be $225,000. The yearly excess of applications over patents for the past three years has been about 30,000. Your committee believes that the sum of $225,000 will suffice to provide increases of $1,000 each in the salaries of 60 of the leading officials in the Patent Office, and increases of $250 to $500 in the salaries of assistant examiners, and still leave $60,000 for five new examining divisions.

To the suggestion that the accumulated surplus of $7,000,000 be used for increase of salaries, your committee thinks a satisfactory answer is that given by Commissioner Moore in his annual report for 1911, namely, that such accumulated surplus should be applied to the purchase of a site for a new Patent Office Building and for its erection. A copy of that report of the Commissioner accompanies this report.

Further answering question 19, your committee is of opinion that the present system of design fees is often inequitable to the party who pays the large fee for a long term patent and later finds his application refused. We therefore recommend that in all design applications there be a fee of $10, payable on filing the application, with the option to the applicant of paying on the allowance of the application an additional fee of $5 for a seven-year term patent, or $20 for a fourteen-year term patent.

20—Where an assignment covers more than one patent, should there be an additional fee for each patent in addition to one? Answer: Yes.

Transposing Fees Will Produce $160,000 More

21—If the expenses of the patent office are not to exceed the revenues from fees and a larger annual appropriation than is now made is necessary to provide a sufficient number of examiners, to pay the examining force adequate salaries, and to make the office more efficient, would an increase of the application fee from $15 to $25, and reduction of the final fee from $20 to $15 be justified?

Answer: See answer to question 19.

22—What criticisms, if any, have you of fees of the office, other than the fee for filing an application for patent and the final fee?

Answer: See answers to questions 17 and 19.

23—What changes, if any, should be made in the laws or procedure of the Patent Office, with reference to trade marks, prints and labels?

Answer: No recommendation at this time.

24—While the subject is not covered by the resolution of Congress, the commission will receive such comment as you may wish to make upon the bill pending in Congress for the creation of a Court of Patent Appeals, to have the jurisdiction in patent cases now exercised by the Circuit Court of Appeals.

Answer: This committee has already passed a resolution urging the enactment of the bill referred to.

The recommendations contained in the above answer to the Commission's queries represents the opinion of 3000 lawyers practicing at the New York County bar, and are in line with those submitted from the bar associations of the whole country generally.

In effect the enactment of a law based upon such recommendations would save time in the Patent Office and money to applicants for patents, besides lending an additional element of certainty and security due to greater efficiency in the office itself.

One of the chief troubles experienced in the Patent Office in recent years has been the difficulty in retaining competent men as examiners. The salary of the office was so small that as soon as one gained skill he was taken away by larger salary and prospects.

The committee which framed the answers consists of the following prominent members of the patent bar: Samuel R. Betts, J. Edgar Bull, Park Benjamin, George E. Cruse, Samuel Owen Edmonds, Philip Farnsworth, Charles C. Gill, Livingston Gifford, Hubert Howson, Harry G. Kimball, Harry E. Knight, William H. Kenyon, Alfred W. Kiddle, William G. McKnight, Charles Neave, John C. Pennie, William A. Redding, John Jerome Rooney, James L. Steuart, A. Parker Smith, Alfred Wilkinson.

Short Receivership, Matheson Hope

W. C. Sheppard has been appointed receiver for the Matheson Automobile Company of Wilkes-Barre, Pa., in the United States District Court. Mr. Sheppard has been president of the corporation since the reorganization about a year ago. The nominal assets of the company are estimated at $1,000,000 and the liabilities are placed at $600,000.

It has been announced that the receivership is to be very brief, extending over a period of only about 3 weeks. It was friendly in its inception and was intended, according to the announcement, to stave off insistent creditors until the plans for refinancing the company are perfected.

The company made sharp retrenchments at the time of the reorganization, and has done a good business since. According to statements from the company, its basic condition is good and the legal steps resulted from a temporary lack of capital coming at the height of the non-productive season.

Nantucket's Motor Troubles

BOSTON, MASS., Dec. 21—Not until it has a town meeting at which all the islanders may vote will the troubles over motor vehicles on Nantucket, an island off the Massachusetts coast, be settled. The islanders succeeded in getting a law through the legislature a couple of years ago excluding motor cars, but recently the selectmen bought a motor fire wagon and it has been delivered. But the law does not make any exception in favor of fire wagons and some of the islanders who are in favor of automobiles say that if the selectmen allow the machine to be run they will have the firemen summoned into court for breaking the law. So the vehicle is somewhat of a white elephant at present. A special town meeting will be called to settle the matter, and it is expected that the legislature will be appealed to next January to straighten out the troubles some way or other.

Stewart-Warner Merger

Speedometer Manufacturers Sell Out To Virginia Corporation Capitalized at $11,000,000

Litigation of Patents Now Pending Said To Be Unimportant Because of Advance in Industry

CHICAGO, Dec. 23—*Special Telegram*—The Stewart-Warner Speedometer Company, a Virginia corporation of $11,000,000 capital, has just been formed and has purchased the plant and patents of the Stewart & Clark Manufacturing Company, Chicago, manufacturers of the Stewart speedometer, and also the plant and patents of the Warner Instrument Company, Beloit, Wis.

This new company has $1,000,000 preferred stock and $10,000,000 common stock.

Official announcement has been made that J. K. Stewart is to be president of the new corporation, but the remainder of the officers have not been selected. C. B. Smith will be general manager. The suit now pending in the United States District Court, Southern District of New York, has not been dismissed. Announcement has been made, however, on the part of Stewart & Clark, that the principle involved in the patent in question is not important to modern practice and the chances favor a dismissal because of the problematic value of a decision on a point not involved in present manufacture.

The physical properties of the Stewart and Warner companies will be continued as at present, that is, the Stewart & Clark Chicago plant and the Warner Beloit plant will continue manufacturing the same class of speedometers that they have in the past and marketing them under their respective names.

There will not be any change in the management of these plants or in the selling organizations connected with them.

This purchase of the two companies brings the holding of all speedometer patents of each company under a single control, and so the long drawn out litigation on the subject of magnetic speedometers between the two companies will be brought to a close.

The patent suit has been in the courts for many months.

The purchase of these two companies in the closing days of the year comes as a climax of a series of unions of this nature in the motor industry, the biggest previous one during the year being the Goodrich-Diamond deal.

Western Electric-Pittsfield Allied

CHICAGO, ILL., Dec. 21.—The reported rumors of an alliance between the Western Electric Company and the Pittsfield Spark Coil Company have been officially confirmed by both parties concerned.

Under the arrangement between the two companies the entire line of Pittsfield products, including magnetos, spark coils, spark plugs, timers and switches, are now to be marketed exclusively by the Western Electric Company, under the name of Western Electric-Pittsfield. For a while the Pittsfield Company will continue to sell some magnetos direct.

Multiwheel Drive Company Formed

WASHINGTON, D. C., Dec. 21.—The American Motor Traffic Company, incorporated under the laws of South Dakota, was formally organized in Washington, D. C., December 18. The directors of the company are E. S. Alvord, president Littlefield & Alvord Express Company, president; S. J. MacFarren, manager Engineering Searching Company, first vice-president and acting manager; W. J. Moore, president The Moore Company, second vice-president; A. L. Kley, of New York City, secretary; J. C. Muncaster, of Washington, and J. C. Menoher, of Pittsburgh.

The company will specialize in heavy duty commercial motor vehicles of the pivoted spindle, multiwheel drive and steer type, with flexible load suspension and balance, and also in liquid fuel combustion engines and vehicle accessories. Many other items of improvement in vehicle construction are controlled by the company under various patents granted to MacFarren, Thomas and others and further protected by special trade marks.

The company is empowered to operate, as well as manufacture, motor vehicles for all uses, and proposes to establish freight, express and passenger services in response to demand, through its exclusive state agencies or auxiliary companies which will be located with reference to convenient transportation and distribution of product.

Crude Oil Situation Is Acute

MILWAUKEE, WIS., Dec. 21—The crude oil situation in Milwaukee, where an aggregate of more than 15,000,000 gallons are used annually, has become critical, following the announcement of the Standard Oil Company that after January 1 no more crude product would be sold on account of the necessity of utilizing all of its crude supply to the production of the higher distillates, such as gasoline, benzine, naphtha and kerosene.

A second blow was struck late last week, when the independent oil companies, which agreed to continue to supply crude to Milwaukee users, issued a new price list, which increases the price from $2.50 to $3.50 per 100 gallons to $5.70 to $6.25 per 100 gallons. The advance is practically prohibitive, and with a supply greatly reduced it has become necessary for manufacturers to cast about for a substitute. As coke is about the only available substitute, it will be necessary for manufacturers to almost

Automobile Securities Quotations

The stock list made some good recoveries from the depression of the earlier part of December, during the past week. The tire stocks were all strong and higher, and nearly all of the automobile manufacturing issues showed some degree of strength. International was the exception, yielding moderately to the announcement of the new financing which involved the retirement of 55 per cent. of the common to form the basis of a bonus to the lenders of $1,500,000 to the company.

wholly rebuild their furnaces at vast expense, and the cost of manufacturing crucible steel will advance in a corresponding proportion.

The A. O. Smith Company, of Milwaukee, produces more than 60 per cent. of all the pressed steel motor car frames used in America The Smith concern uses nearly 1,000,000 gallons of crude oil per year The largest user of crude is The Falk Company, which is one of the largest manufacturers of kerosene gas engines in the world, and takes 2,000,000 gallons per year. The Allis-Chalmers Company and National Brake & Electric Company use 1,250,000 gallons and the Sivyer Steel Casting Company, a large producer of crucible steel, uses 750,000 gallons. The A. O. Smith Company has a contract for crude supply until April 1, 1913, but has already installed a gas producer plant and contemplates the use of electricity as the primary source of heating after April 1. The crucible steel industry is watching developments closely, but the rise in price seems unavoidable.

Grabowsky Creditors May Get Half

DETROIT, MICH., Dec. 23.—*Special Telegram*—Referee in Bankruptcy Lee Joslin has postponed the sale of the property of the Grabowsky Power Wagon Company, adjudicated bankrupt about a month ago, until Thursday. When sealed bids were opened at the office of the referee to-day only two offers were received. One bid was from the Joy Realty Company of Detroit, which bid $137,300 for real estate, machinery and equipment, which were appraised at about $188,600; the other offer was from Winternitz & Co., of Chicago, which offered to take the property with the exception of the real estate and sell at 121.2 per cent., guaranteeing to net $55,000. The total under the two bids would be less than $175,000 it is believed, and Referee Joslyn is confident at least $200,000 can be realized, which would give the creditors 50 cents on the dollar. This would be a fairly satisfactory showing.

Market Changes for the Week

FEW developments of interest occurred in this week's market of materials, so far as prices were concerned, despite the fact that the general tone of trading was firm, so that a few substances experienced appreciable advances in price. The most important feature in this respect was tin, which fluctuated over a range of 35 cents per 100 pounds during the week, but rose sharply the last two days and closed 15 cents higher than it had opened. Copper prices remained practically what they were last week, and no change in the price of steel has been recorded, whereas lead fell off slightly.

Petroleum and gasoline remained at their former quotations and there are no indications that future changes of price will be of a downward nature. The rest of the lubricants and oils have likewise remained at their old prices, except cottonseed oil, which rose from $6.15 to $6.37 a barrel during the week.

Stromberg Starts Suits

Begins Action to Adjudicate Ahara and Richard Carbureter Patents With Zenith as Defendant

Henderson Company is Moving Into Larger Factory and Announces Engagement of Production Manager

CHICAGO, Dec. 21—Suit was brought on December 12 by the Stromberg Motor Devices Company *vs.* Zenith Carburetor Company under two patents, one the Ahara patent granted in 1901, and the other a Richard patent granted in 1905.

The Ahara patent is one which has not attracted general public attention, although it appeared comparatively early in the carbureter art and has extremely broad claims upon a carbureter without any moving part. The inventor and patentee, Ahara, is an engineer of wide practical experience, and his invention was made in connection with actual development work, and has been commercially employed.

The Richard patent is directed toward a specific feature of construction, which, however, is employed by and is said to be necessary to any plain tube carbureter. It covers a U-shaped tube in certain relation to the gasoline supply, one end of the U-shaped tube extending into the mixing chamber, the other end being exposed to atmosphere, combined with other features which are found in all modern carbureters.

DETROIT, MICH., Dec. 23—*Special Telegram*—Notice of the filing of a suit has been given by the Stromberg Motor Devices Company, Chicago, against the Zenith Carburetor Company, Detroit, alleging infringement of the Ahara patent covering a carbureter without moving parts and Richards patent for U-shaped spray nozzle construction, the former dated 1901 and the latter 1905.

While not yet in the court, the case will be brought in the Federal Court here and will probably not come up for 6 months, as the courts are very lenient in patent cases of this nature.

V. R. Heftler, of the Zenith company, states that the suit will be fought and that there is no ground for action. The local attorneys for the Zenith company will be Wm. M. Swan, of the firm of Kenna, Lightner, Oxtoby & Oxtoby. Bigwell & Burnes, of Pittsburgh, who have handled patent litigation for the United States Steel Corporation, have also been secured by the Zenith company, which has not yet made any plans for its line of defence, as it is very difficult to determine the exact status of the matter until the taking of the first testimony, the bill of complaint having the usual vagueness.

Henderson Moving to Larger Factory

INDIANAPOLIS, Dec. 21.—The moving of the factory into the new addition has caused the Henderson Motor Car Company to add to its factory staff J. M. Smith in the capacity of factory production manager. Mr. Smith for several years was assistant superintendent in charge of production in a big Detroit factory. He comes to the Henderson from the Cole Motor Car Company, of Indianapolis, where he has been employed in the capacity of factory manager.

The Henderson factory will be closed down until January 1 while the different departments are acquiring additional space in the new factory building which will give the Indianapolis plant a floor space of 55,000 square feet. Before production is resumed an inventory will be taken and the first of the year an additional force will be added and the production will be doubled for January and February and trebled in the ensuing months of the 1913 season, according to announcement.

Connersville Seeks To Hold Lexington

Securities Company Offers 25 Per Cent. for Claims Against Embarrassed Concern Before Trying Reorganization

Imperial in Its New Factory Announces a Six-Cylinder Model—Gasoline Up at Milwaukee—Other News

CONNERSVILLE, IND., Dec. 21—In an attempt to continue the Lexington Motor Car Company as a going concern here, the Connersville Securities, a corporation composed of local capitalists, have made a proposal to the creditors of the manufacturing company to purchase the claims against the company and to refinance the project to a sound basis.

The proposition is for 25 per cent. in cash within 30 days after proper delivery. The new organization is still in shadowy form but will be developed as soon as the settlement of the claims is consummated.

The troubles of the company arose from the failure to secure new capital after entering into a contract to produce cars worth $1,500,000 a year. A meeting of the creditors was called and a committee appointed. The proposal of the securities company was the best received. Nominal assets are placed at $134,000 and liabilities at $140,000. Actual assets under forced sale would bring very much less according to the figures of the creditors' committee.

Imperial in New Plant to Build Six

JACKSON, MICH., Dec. 21—The Imperial Automobile Company now is located in its new plant, formerly the Buick factory, in the western part of the city. The building is the largest factory edifice in Jackson. A new model will be manufactured by the company in the new plant. This model will be a six-cylinder car, the only one to be made in any of the four automobile companies in Jackson. Motors and other parts of the car will be made in the new factory. The new plant and increased force will insure the prompt delivery of cars, no matter how great the demand.

The company began operations in Jackson September 1, 1908, with 25 workmen and an output of only 25 cars in the first season. Last season 300 men were employed. It is expected the force will be increased to 500 after the first of the year. Last season the company was compelled to forfeit the sale of 200 cars because of a lack of facilities.

Gray & Davis Not a G. E. Branch

Owing to the misinformation of a correspondent, THE AUTOMOBILE for December 19 contained a reference to "the Gray & Davis Company of Boston, a branch of the General Electric Company." William Gray, president of the company, states that his company is no branch of any concern.

Britons Seek Home Motor Fuel

LONDON, Dec. 10—An announcement has just been made that the Society of Motor Manufacturers and Traders has voted the sum of 2000 guineas towards research in connection with the production of a British produced fuel for motor engines, and very shortly will issue the terms and conditions under which it is proposed the prize shall be offered.

Generally speaking, the conditions will specify that the fuel must be home produced at a commercial price, be suitable for the existing motor engines, and manufactured or produced from materials available in this country.

It is considered by many people that benzol can be produced in sufficiently large quantities to compete with imported petrol. At present the production of benzol is comparatively small, and can at the present time be sold at about 1 shilling per gallon retail. The difficulty, of course, is that with benzol there is a ready market for certain manufacturing purposes, and if there were any great demand in connection with motor cars the price would immediately be raised.

Certain new processes for the production of benzol have lately been perfected, which will materially increase the production. However, the matter is to be most thoroughly investigated and both the Society of Motor Manufacturers and Traders and the Royal Automobile Club are combining with a view to obtaining the desired end, namely, the production of a home made fuel.

Free Course in Road Building

ST. LOUIS, MO., Dec. 21.—A 2 weeks course in road building will be given by the School of Engineering of the Missouri State University in February. A description of the work was a part of the report of State Highway Engineer Curtis Hill to the Missouri Association of County Judges which met in Columbia on December 10.

The course will be free to any one who desires to take it. Other than the lectures by university professors and practical road builders there will be demonstrations, tests and experiments in the engineering laboratories. If the course is well attended it may be lengthened and be made a part of the regular university work next year.

Gasoline Up Again in Milwaukee

MILWAUKEE, WIS., Dec. 21.—An advance of 1 cent in the prices of all grades of gasoline was made on December 20 to all Milwaukee garages by the oil supply companies. Garages are now paying 15 cents per gallon for 60 to 63 test; 17 cents for 65 to 68 test; 18½ cents for 70, and 19½ cents for 72 to 74 test, to which the garages add about 4 cents. A year ago gasoline was on the decline, ranging from 10½ for 58 to 60 test to 15 cents for the highest test, but with the approach of winter this year prices kept on advancing as during the summer.

In Wisconsin all gasoline, as well as other petroleum products, are inspected by the state department of illuminating oils.

Texas Census Shows 35,187 Cars

AUSTIN, TEX., Dec. 21.—In a statement just issued by the Texas Commercial Secretaries and Business Men's Association the results of the census taken by that organization of the automobiles in Texas are given. These are the first statistics that have ever been gathered on this subject in this state. The report follows:

"There are 35,187 automobiles in Texas and their total value in approximately $43,983,750. Compared with 1911, this is an increase of 5204, or 17.3 per cent., in number and a decrease of $1,016,250 in value. Ninety-five and one-half per cent., or 33,623, of the cars in the state are used for pleasure purposes, while 1564, or 4.5 per cent., are in commercial use. There are 105 different models in use in Texas and the price ranges from $400 to $10,000 each. The average price per car is $1250, compared with $1500 in 1911 and $2137 ten years ago."

Truck Club Elects and Plans for Show

At the annual meeting and election of officers of the Motor Truck Club of New York, D. C. Fenner was re-elected president; Emerson Brooks, vice-president; C. E. Stone, treasurer, and E. L. Howland,, secretary. A new board of managers also was chosen, consisting of E. W. Curtis, Jr., George H. Duck, Karl L. Frederick, J. W. Perry, A. W. Robinson, W. Oscar Shadbolt and Arthur J. Slade. The selections were unanimous, no opposition ticket being presented.

It was provided that in the future no member be chosen for the offices of president or vice-president for two succeeding terms and that the terms be limited to 1 year.

Extensive preparations are under way for an entertainment in the novel form of a breakfast, to be tendered a number of leading men in the industry, January 21, during the week of the motor truck show. The committee in charge plans to arrange for addresses by prominent officials of motor truck companies, and an attendance of more than 200 is declared to be assured for the occasion.

A report from the membership committee showed an increase of more than 100 per cent. within a year. Permanent quarters have been taken at 1845 Broadway, and a clerical force is maintained to handle the details of the work of the club.

The new Motor Truck Club Bulletin, the monthly publication of the organization, made its initial appearance among the members.

Lion Sale Brings Out Only Low Bid

DETROIT, MICH., Dec. 23.—(*Special Telegram.*)—As the highest bid for the property of the Lion Motor Car Company, of Adrian, Mich., was too low, Referee in Bankruptcy Lee Joslyn has postponed the sale to December 24. The property was appraised at $33,401.73 and the highest amount offered at the sale at Adrian was $7,000. Referee Joslyn thereupon postponed the sale. After the sale the creditors will elect a trustee.

Buffalo Electric Expands Service

BUFFALO, N. Y., Dec. 21.—The Buffalo Electric Vehicle Company has made an important addition to its facilities in Buffalo, having acquired the Buffalo Motor Vehicle Service Company. The latter company has a complete garage and service station and is closely affiliated with the Buffalo General Electric Company and the Rochester Railway & Light Company. The property acquired includes the garage and service station located on lands immediately adjoining the factory and service station of the Buffalo Electric Vehicle Company.

As a part of the same transaction in purchasing this company, the Empire State General Vehicle Company, of Rochester, closely affiliated with the Rochester Railway & Light Company, has taken the agency for both Buffalo Electric pleasure vehicles and commercial trucks for Rochester and vicinity.

Minnesota Plans Horsepower Tax

MINNEAPOLIS, MINN., Dec. 23—Plans are on foot to revise the Minnesota law governing the taxation of automobiles, substituting a horsepower tax for the present 3-year registration license fee and the personal property tax. It is estimated in this way a large sum can be raised for State road maintenance. The new law went into effect in 1911.

The automobile registration began in 1909 with 7000 licenses. The next year the registration was 12,000, and the third year 19,000. This year the total is 28,700, at $1.50 each. From 3300 chauffeurs $3 each has been realized, from 4700 motorcycles $1.50 each, from 250 dealers and manufacturers $10 each, a total of $70,000, of which $50,000 is net.

Delaware Motorists to Banquet

WILMINGTON, DEL., Dec. 20—The Delaware Automobile Association is planning for a monster State automobile demonstration in Wilmington on January 13, on which date the association will hold a banquet in the Hotel duPont, which is now being completed at a cost of $1,000,000.

Ford Surplus Now At High Record Figures

Balance Sheet Shows That Company Has $14,745,000 Over All Charges, of Which $6,400,000 Is Cash

Philadelphia Parts Company Reports Excellent Business and Fine Prospects for the Coming Year

DETROIT, MICH., Dec. 21—According to the balance sheet for the fiscal year to September 30, just issued by James Couzens, secretary and treasurer of the Ford Motor Company, the assets of the company at the end of the year amounted to $20,815,785.63, of which $6,400,100.66 represented cash on hand and in banks.

Other items included in the assets were: Michigan municipal tax exempt bonds at cost, $1,075,051.48; accounts receivable, $230,912.17; merchandise inventories at cost, $6,629,533.83; other investments, $7,772.04; prepaid expenses, $44,591.07; real estate, $820,636.97; buildings and building fixtures, $2,596,115.61; factory equipment, $371,110.90; office furniture and fixtures, $58,059.39; power plant, $301,166.13; machinery, $1,542,800.89; tools, $566,510,17; patterns, $66,884.06; machinery, tools and equipment at branches, $52,746.30; patents, $51,793.96.

Included in the liabilities were: Accounts payable, $2,261,026.63; accrued pay rolls, $149,166.45; accrued salaries, $12,327.45; accrued expenses, $178,766.10; contract rebates, $58,350; reserve for refunds to take care of reduction in price, $75,000; reserve for employees' bonus, $242,033.80; reserve for bad debts, $3,655.04; reserve for depreciation of fixed assets, $752,626.89; reserve for depreciation of patents, $51,793.96; reserve for fire insurance premiums, $11,900.40; reserve for unearned profits (branches), $284,043.34; capital stock, $2,000,000; surplus, $14,745,095.57; total, $20,815,785.63.

Evans Reports Good Year and Prospects

Merchant & Evans Company, with headquarters at Philadelphia and factories at Philadelphia, Chicago and Warwood has issued a review of its business for 1912 in which it is shown that its various automobile accessory departments have had a prosperous and busy year. The company makes clutches and other parts for automobiles in connection with a large business in outside lines. Powell Evans, president, states that the activity of the company has kept abreast of the rapid development of the industry. Prices and profits have been larger than in 1911. Collections have been excellent. All factory facilities of the company have been taxed to fullest capacity and night shifts were employed for a portion of the year. President Evans takes an optimistic view of the prospects for 1913. The factories are well booked into the second quarter of the year.

Will Sell Stock for Assessments

DETROIT, Dec. 21—The Advance Machine Company, formerly the Hale Motor & Machine Company, has given notice through its president, Peter M. Detzler, and its secretary, R. J. Brennan, that January 22, at the office of the secretary, 654 Franklin street, Detroit, at 10 a.m., enough stock of Carl I. Overton, John K. Teetzil, William W. Johnson, J. L. Allen and J. G. Bayerline will be sold at public auction to pay assessments levied upon the stocks held by these men, together with interest and cost of the sale. The amounts alleged to be due are: Overton, $375; Teetzil, $150; Johnson, $225; Allen, $300; Bayerline, $300.

Practical Method for Testing and Improving the Water-Cooling System of Any Car in All Its Features and Without the Use of Special Apparatus—Another French Window Slide Design—Praise for Cheapest Road Tar

ESTABLISHING a Cooling System by Experiment Combined with Calculation.—After determining the principal factors in the cooling system of a vehicle by calculation the manufacturer is sometimes disagreeably surprised to discover that the result differs from that which it had been the intention to realize. It is therefore of the highest importance, when a new model is being tested out, to devise practical means for controlling and correcting those features in the design of the motor and the vehicle which have to do with this matter. In order to make sure that the entire cooling system will always operate satisfactorily and yet not cool the motor so much as to reduce its efficiency more than necessary or be so large as to constitute an encumbrance, experiments must be conducted with the vehicle under the most unfavorable conditions which are likely to be encountered. Such conditions are realized when the vehicle climbs a long grade on the low gear with the motor developing its maximum power while the vehicle speed is the lowest possible. The grade must be long enough to establish a constant condition and the external temperature should be that of the hottest days of summer. In practice it is nearly impossible to realize this combination of circumstances just when it is wanted. Hills of the right length and grade are not usually available, and one which might be suitable for one model would probably not suit for another model of the same manufacture. The subject, on the other hand, is gaining in practical interest from the fact that harder work is now demanded of the motors than formerly and that truck motors especially are held down to minimum sizes with a view to fuel economy and lower first cost.

A method which has been used to great advantage by one firm and which permits the thorough testing of the cooling system of any vehicle on roads of any variety of grades and at any time of the year should therefore be of interest.

Let A, Fig. 1, be the vehicle to be tested. By means of a rope 15 to 20 meters long there is hitched to it a trailing vehicle B which is to act as a brake of a power varying according to the grade of the road, so as to serve to produce conditions equivalent to those met on a long hill of a certain and constant grade. Vehicle A is occupied by two men, the driver and an assistant; vehicle B by one man only. Vehicle A is equipped with a speed indicator, and its driver must know what speed in kilometers per hour corresponds to the maximum power output of the motor on low gear. It is the function of the two drivers to maintain their vehicles going at this speed while the motor runs at its highest power with the throttle open.

To this end the driver of vehicle B places his speed lever at low or second gear and, watching the signals given him from the driver of vehicle A, opens or closes the channels in his carbureter more or less, so as to create at all moments the brake resistance against the progress of vehicle A which is required for maintaining the uniform vehicle speed. In practice this method of braking by the motor [presumably with the gas and spark shut off] has been proved efficacious without it being necessary to resort to the mechanical brakes, provided only a road is chosen which has no strong downhill slopes.

Vehicle A is equipped with four thermometers. Thermometer No. 1 is placed on the body panel and gives the temperature of the atmosphere. No. 2 is placed under the hood in the current of heated air which is driven away from the motor and it measures the temperature of air which has passed through the radiator. Thermometer No. 3 is of the laboratory type and is placed in the current of water which is piped from the cylinders to the radiator, the arrangement being indicated in Fig. 3. Thermometer No. 4, also of the laboratory type, is placed in the water piped from the radiator to the cylinders.

During the road test the assistant on vehicle A takes the temperatures of all four thermometers every 15 minutes and tabulates them. If the vehicle is not equipped with a speed indicator the assistant may time the vehicle by means of a watch and a cyclometer or the kilometer stones at the roadside, but a speed indicator is preferable, as it enables the driver personally to gauge the speed of the vehicle more directly and accurately.

On returning to the factory, the discharge of the pump at maximum power output of the motor and with all resistances included is measured. For this purpose the rubber tube joint M at the entrance to the radiator is undone, and the water from the pipe is received in a graduated trough for a measured length of time while the required additional water is poured into the system through the reservoir of the radiator.

All the factors are now ascertained which are needed for determining how the cooling system will behave under circumstances which tax it most heavily.

[An exception may be noted for the case when the vehicle is travelling under otherwise most severe conditions and also with the wind coming from behind, or from the side, causing a certain amount of suction in front of the radiator and also perhaps interfering directly with the discharge of heated air at the rear of the motor. But these factors may be taken care of, perhaps, through the margin of safety which should be allowed in the system, anyway, to provide against the diminished convection and radiation of heat occurring in case of calcareous or other settlement in the radiator conduits. It will be noticed, by the way, that the computations in the following, by means of which shortcomings in the cooling system may be located in one feature or another of the whole motor or vehicle design, are applicable even if the preparatory testing is done with the vehicle at a standstill working against an adjustable hydraulic dynamometer, for example, rather than on the road and with the resistance regulated by means of a trailing vehicle.—Ed.]

THE FACTORS ENTERING IN THE EXPERIMENTS

The known factors are now:

Q, the discharge of the pump in liters per second;

1 (one), the specific heat of water;

D, the temperature centigrade shown by thermometer No. 3;

d, the temperature centigrade shown by thermometer No. 4;

T, the temperature centigrade shown by thermometer No. 2;

0.237, the specific heat of air at constant pressure;

t, the temperature centigrade shown by thermometer No. 1;

V, the speed in meters per second of vehicle A;

S, the total area of the air channels in the radiator of vehicle A;

L, the coefficient of contraction in the stream of air, which depends upon the conformation of the air channels in the radiator and has been determined as varying from 0.64 to 0.80. [This probably refers to cellular radiators. It is also commonly understood that the contraction of the stream depends not only upon the shape of the channels but also somewhat upon the velocity of the air current.—ED.]

g, the density of air under the pressure H and at the temperature t, which equals $1.293 \frac{H}{760} \times \frac{1}{1 + 0.00367 \times t}$ [see text books, under specific heat of gases];

x_1, the weight in kilograms of the air actually passing through the radiator; and

x_2, the weight of air which ought to pass through the radiator.

THE TWO PRINCIPAL EQUATIONS

The number of calories taken from the cooling water during one second is evidently absorbed completely in the air which passes; which fact can be written:

$$(1) \qquad Q \times 1 \times (D - d) = x_1 \times 0.237\ (T - t)$$

But the weight of air which ought to pass through the radiator is:

$$(2) \qquad x_2 = V \times S \times L \times g$$

$$= VS \times 0.64 \times 1.293 \frac{H}{760} \times \frac{1}{1 + 0.00367 \times t}$$

The first test is made without ventilating fan and is desginated as test O.

The second test is made with ventilating fan and is designated test P.

DEDUCTIONS MADE FROM THE DATA

Test O.—The radicle x_1 is determined from equation (1), and gives the weight of air which really passes through the radiator. Similarly, the value of x_2 is determined from equation (2) and gives the weight of air which ought to pass through the radiator.

If x_2 is found to be larger than x_1, the reason must be that the discharge-openings for the air current under the hood are insufficient; and they are consequently to be modified. It may be noted that this is a frequently occurring cause of inefficiency in the cooling system. The radiator is well calculated. The circulation functions normally. The ventilating fan works properly. And yet the motor steams. It is because the heated air has no sufficient exit and blocks the ventilation of the radiator. This point will bear watching.

Test P.—It is operated in the same manner as test O, and the same conclusion may be drawn from the data obtained, but the value for x_1 obtained from equation (1) under test P, compared to that found under test O, discloses the real effect of the fan at the vehicle speed V, which is the lowest at which full power can be developed and therefore the crucial one.

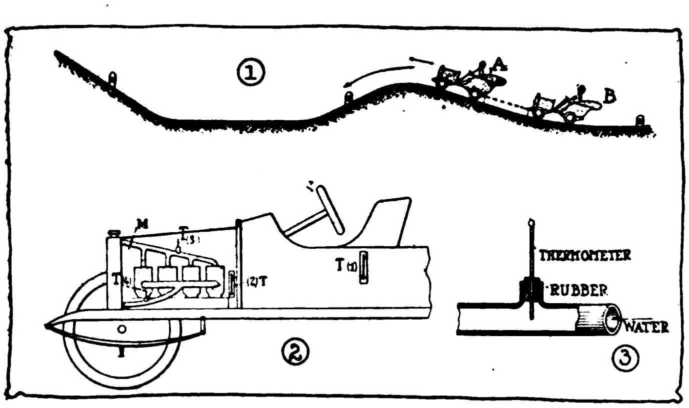

Fig. 1—General outline of method for improving the water-cooling system of a car. Fig. 2—Disposal of thermometers on car A. Fig. 3—Thermometers in the water circuit

The delivery of the pump has been measured; it should be from 65 to 80 liters per minute. [The author seems here to have in mind an individual instance which has not otherwise been specified in his article as it is printed. It can scarcely be supposed to be his contention that Q should not have a wider range of variation in motors of different types and sizes than from 1 1/12 to 1⅓ liter per second. Probably his specific reference to the tests which have come under his observation has been eliminated in the publication of his article.—ED.]

The difference between D and t makes it known whether the cooling will be sufficient for the hot days of summer. Suppose that the atmospheric temperature is 2 deg. C. and that of the water coming out of the motor is 84 deg. C.; then D minus t equals 82 deg. C. Now if the summer brings a temperature of 35 deg. C., it may be inferred that the water, when it comes out of the motor, will tend toward a temperature of 82 plus 35 degrees, which is 117 degrees; in other words, the water will be boiling away, and the cooling system which showed a temperature as high as 84 degrees for the water issuing from the cylinders during the colder weather should have been modified.

D minus t must not exceed 53 to 60 degrees if the efficiency of the cooling system shall be assured for all circumstances.

The value for $D - d$ is known and gives the more or less efficient utilization of the radiator. This value should, however, be as small as possible, since a low value for this factor means a hot radiator and the amount of heat absorbed by the air is proportionate to the difference in temperature of the radiator and of the air. To get good cooling with this factor small, circulation must be rapid. It is therefore reduced by suppressing resistances in the water circulation and by increasing the pump capacity.

The number of calories yielded up by the motor to the cooling water is expressed in the first member of equation (1). Designating this number as K, the number of calories disposed of per unit of radiator surface is obtained by dividing K by S.

After ascertaining that the air circulates satisfactorily and that its discharge at the rear of the hood is unimpeded, if it is still found that the radiator is inadequate—as may be recognized by finding that D minus t is larger than 53 to 60 deg. C.—a value for D which makes $(D - t)$ smaller than 53 to 60 deg. C. is substituted in equation (1); the corresponding new value for x_1 is now determined and is inserted for x_2 in equation (2). From this a new value for S is found. And from this new value for S it may be decided how the dimensions of the radiator should be changed. It must be observed, however, that the increased amount of air corresponding to the new value for x_1 will pass efficiently through the radiator and the rear exits, and also that the fan is established in unison with the new condition.

APPLYING THE METHOD TO A THERMO-SIPHON SYSTEM

In the case of a cooling system operating without a pump it is not possible to measure the amount of water Q which flows to the radiator per second. The proceeding must be different. The pan is removed as well as everything else which might impede the flow of air behind the radiator; if necessary even the dashboard. Under these conditions the amount of air which passes through the radiator is evidently identical with that which should pass through it, considering its design, and this amount x_1 may be determined from equation (2). And by inserting this value for x_1 in equation (1), Q may be determined from the latter. In this manner the method followed offers a means for ascertaining the water flow in a thermo-siphon system; something which it has not been found possible to do by pure experimentation. And the rest of the calculations needed for the examination and correcting of the system in each case presents no special difficulties.

DETAILS OF THE ROAD WORK

Some difficulty in applying the method might be feared to exist with regard to maintaining a constant speed by varying the braking effect of the trailer B. But in reality there is no such difficulty. The two drivers of A and B must evidently have a little practice in operating under the required conditions and must agree between them on a code of suitable signals. A speed indicator may also be placed on vehicle B, and its driver can then maintain a constant speed on his own hook. Speed variations of short duration have, for that matter, no appreciable influence on the final results.

The four thermometers should all be placed so that they may be read without stopping the vehicle, as it is quite necessary to have the test carried on without interruption, and while this calls for rather lively action on the part of the assistant upon whom it devolves to take the readings, there is no real difficulty since the vehicle is driven at relatively low speed.

Applied by one of the large French manufacturers this method has rendered it possible to find all weak spots in the cooling systems of different models and to improve them systematically. It calls for no complicated apparatus of any kind and gives very accurate data.—From *La Technique Automobile et Aérienne*. August 15.

—

WINDOW-SLIDE Construction.—Special provisions for facilitating the raising and lowering of windows in the doors or body panels of automobiles continue to engage the attention of designers, showing that some difficulties are encountered at this point, probably by reason of the torsion which is communicated to the vehicle body from the chassis at high speeds. In THE AUTOMOBILE of last week the Hera window-lift was described and reference was also made to the Rawlence window-lift, both of which designs are intended principally for use with the new style of frameless window panes and also are meant to reduce physical effort by means of special mechanical movements and the use of compensating springs, the latter serving to regenerate a little power from the lowering of a window to help in the raising of it. Another and less ambitious design is shown in Fig. 4 and is patented to G. Kutzner of Paris. It is not intended by this construction to oust the ordinary lift-strap from service but merely to provide an arrangement which will operate reliably and uniformly under automobile conditions with the ordinary old style of framed windows, without sticking or rattling. Those interested will find the drawing almost self-explanatory. The sub-figures A, B, C and D represent the positions of the parts at successive stages of raising the window, while E represents a cross-section on the line AA. The door frame or body panel 1 is provided with a recess 2 at each side in which the whole mechanism is lodged when the window is down. Arms 3 slide on each side of the frame in a guide groove 4 in the upper portion of which a metallic piece 5 is secured. The two arms are formed with tenons 6 at their upper ends which slide in grooves 7 formed in the frame 8 of the window pane 9. Another pair of tenons formed as eccentric disks are secured to each arm, at about their middle, and, when reaching the sill, permit a lateral displacement of the window, so that its lower edge comes to rest at 11. The arms 3 also carry tenons 12 at their lower ends and these slide into guide 13 on the metallic pieces 5. The latter are equipped with rollers 14.

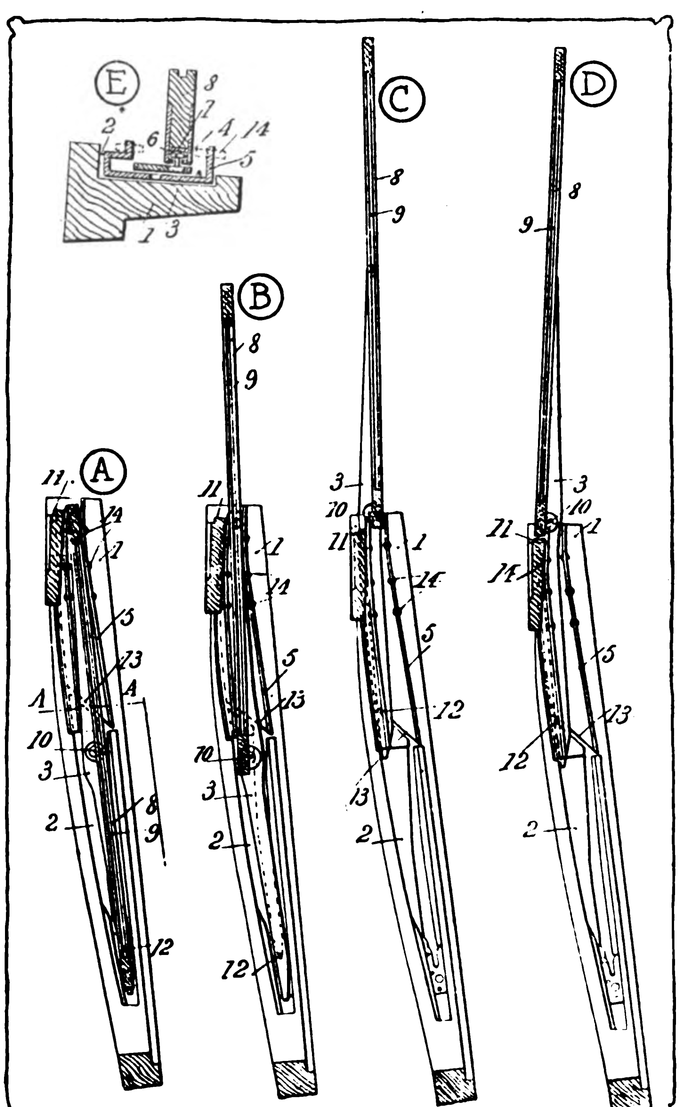

Fig. 4, A, B, C, D and E—Slide design for framed window panes

In the position B the eccentric tenons 10 reach the beginning of groove 7 and carry the arms 3 with them when following this groove until position C is reached. The lower half of frame 8 can then be moved laterally and can be pushed over the eccentric into its rest position. The eccentrics and the tenons 12 in engagement with the welge-guides 13 secure its firmness.—From *La Carosserie Française*, Nov. 15.

PLAIN Coal Tar for Roads.—The use of plain undistilled coal tar from the gas works for the tarring of roads has suffered a considerable setback, mostly by reason of the contentions made by certain investigators to the effect that all vegetation in the vicinity of roads treated with this material suffers heavily. It has also been claimed that fishes cannot live in the waters receiving the drain from such roads. As it is of importance for the improvements of roads to be able to use the cheapest product available, rather than the expensive tar preparations which have been adopted for the purpose in many French towns but which usually scare the taxpayer, H. F. Fischer of Stuttgart, Germany, has gathered data on the subject which it is the intention to lay before the Third International Road Congress to be held in 1913, so as to offset the unfavorable impressions with regard to the coal tar process which were received at the congress at Brussels.

From among the information collected, which has now been published in the Journal of Austrian Gas and Water Engineers, it is noted that the first charges relating to the alleged effects of coal tar, which were made by the French botanist, Dr. Marcel Mirande, with special reference to the sickening of the trees and shrubs in the Bois de Boulogne in Paris, have been refuted through the careful investigations of a Parisian engineer named Griffon. In Bordeaux a prominent street has for several years been treated with ordinary coal tar without a single tree suffering, and among them are silver poplars, maples, oaks, walnut trees and even the sensitive lindens. The macadamized roads at Montpelier have for a number of years been similarly treated, and it has been observed that the magnificent planetrees of this region are now thriving much better than before, owing to the comparative absence of dust under the present conditions. Prof. Saumier of Rouen has ascertained from replies to circulars sent to all departments of France that the ordinary coal tar nowhere is accused of damaging vegetation, except in Fontenay de Comte, where the trees surrounding a public plaza were destroyed. But

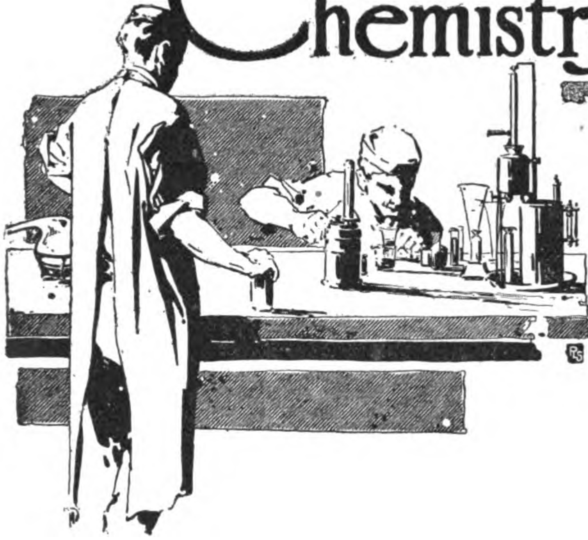
The Chemistry of Cylinder Oils



Professor Jones Answers Professor Gallup's Criticisms of His Articles On the Analysis of Cylinder Oils

NEW YORK CITY—Editor THE AUTOMOBILE—I have read with much interest the letter from David L. Gallup, assistant professor of gas engineering, Worcester Polytechnic Institute, published in THE AUTOMOBILE for December 12. In replying to his communication I will try to confine myself to the three items he mentions.

First—The effect of the flash point on the lubricating value of the oil. **Mr. Gallup states: "The chief argument in the article referred to seems to be that in order to be effective an oil should be of low flash and fire test, and for the specific reason that it burns up clean."** I have made no such statement, and if I had intended this to be what I meant I should have plainly said so. Neither do I think that what I have said will warrant any such deduction.

As for the questions he asks, following this statement, he says they are "ridiculous," with which I fully agree, and they therefore require no answer.

Professor Gallup states that "the best oil for lubrication is one which serves that purpose exclusively," etc.; and when he says that **"At present there is no oil known which will satisfy the last condition perfectly, and the only alternative is to use that which approaches its accomplishment most nearly."** I think he is quite right, **but he does not tell us anything about how to find that oil.**

The next statement he makes is not quite so good. Of course, it is needless to say that the output of these oils is controlled so that the distribution of a new oil requires a ready argument for its adoption, and that the easiest one seems to be that it burns up quickly. This is an absolute misrepresentation. The idea which he seems to put forward is that I am interested in bringing out a new oil. **I am not interested in any oil, I have no oil to introduce, nor am I interested in any way with any one who is selling oil.**

He then says that "another feature of a low-flash oil is that its price is usually lower," etc., and then still argues upon his one idea about burning the oil. Now no one is advising the use of an oil to be burned. We all know that if you burn your oil you will have to replace it. There is no argument in this. In the first part of my article I gave the analysis of an oil which might be considered as a fairly good oil for a cylinder oil. I do not say that it is the only oil to be used; I have shown others equally good, and for some conditions might even be better. But the analysis I gave was a very light oil with a low flash point, and this is what I understand Mr. Gallup condemns. Now as a matter of fact, this very oil is one to which automobile men have given high praise, and the only objection they had was the price, which is about 75 cents per gallon. If this is the cheap oil he is referring to, I would be glad to know what the high-priced ones are. There are higher priced oils. I have one now in my laboratory which sells at $1.00 per gallon. This oil has a flash point of 610 degrees Fahrenheit, and of course the viscosity of this oil is very high. Perhaps this is the oil Mr. Gallup would recommend.

On the fire point Mr. Gallup simply makes a statement which does not seem to have any bearing on anything I have said: Under 3: **"Speaking of the viscosity, he says, many oils show a marked decrease in this quality between 70 degrees Fahrenheit and 212 degrees Fahrenheit, and that this is more pronounced in the case of low-flash test oils than high."** I think that if he will stop to think he will see that this is quite wrong. **This may be his opinion, but it is not borne out by figures obtained.** Let us turn to table B, which appeared in THE AUTOMOBILE for November 21, and look at the first group under brand A. Here we have six oils, of different gravity, viscosity and flash points.

	Flash	Vis. 80	Vis. 212	Drop	Drop%
In No. 1 we have.......	384	3.2353	1.3214	1.9139	59
In No. 3 we have.......	422	6.1764	1.4285	4.7479	76
In No. 6 we have.......	532	58.2142	4.0357	54.1785	93
In M we have..........	325	1.7647	1.1428	0.6291	35

These figures seem to hold fairly well throughout the list. **These are facts, and not opinions, which I think show that Mr. Gallup's statement is not correct.**

He suggests further that if the test for viscosity be made at 212 or 250 degrees, an oil of high viscosity at this temperature should be given the selection. Now if one will look at the table B, of forty oils, it will be seen that there are only three oils with anything that might be called a high viscosity, and these are not considered as automobile cylinder oils, and as far as I know are not in general use for that purpose.

Again Mr. Gallup says, "an oil of low-flash test **must** possess a low viscosity at this temperature." Here again he is wrong. That it is generally the case I admit, but not always. We will take ———, an oil with which he ought to be acquainted. He will find the tests for this oil under brand B. This oil shows a flash of 428, and a viscosity of 1.2500. Now glance down the table to brand J No. 1, and you will find an oil with a flash of only 396, and a viscosity of 1.4285. Thus his statement is not correct.

There is no accident or error in these figures. These oils have been tested more than once, and from more than one source. It is characteristic of the oil in brand J.

Reverting to the flash point again, I notice that Mr. Gallup asks, "How long would the engine of a racing car stand up under the use of a low-flash oil?" He says the temperature of the cylinder under these conditions is so high that such an oil would be disintegrated before it had the chance to perform its function. Mr. Gallup has, so far as I understand, been claiming that this light oil would be burned up. Now **there is quite a difference between "burning" and "disintegrated,"** and in either case, to answer his question intelligently, it would be well to know about what the temperature of the cylinder is. Will he kindly let me know?—PROFESSOR W. JONES, Analytical and Consulting Chemist.

Criticisms of Non-Poppet Valves To-Date

European Engineers Lead in New Constructions of Rotary and Slide Valves—Keeping the Valves at Low Temperature and Preserving Their True Shape Are Points Well Appreciated Abroad

Internal Cooling Is Not Absolutely Necessary and Properly Designed Valves Often Operate Well Without It—No Conclusion To Be Taken Yet As to Straight Cylindrical or Tapered Rotary Types

By Eugene P. Batzell Installment II

A COMPARISON between the new valve designs offered here and abroad indicates that Europe is closer to some ultimate successful arrangement of rotary or piston valve. Many of their new constructions prove that they have been originated by persons with experience in this field. At least it is evident that the concerns there have been carrying on much experimenting because their new constructions mostly are designed to avoid certain defects, which could not have been detected otherwise than by practical experiments.

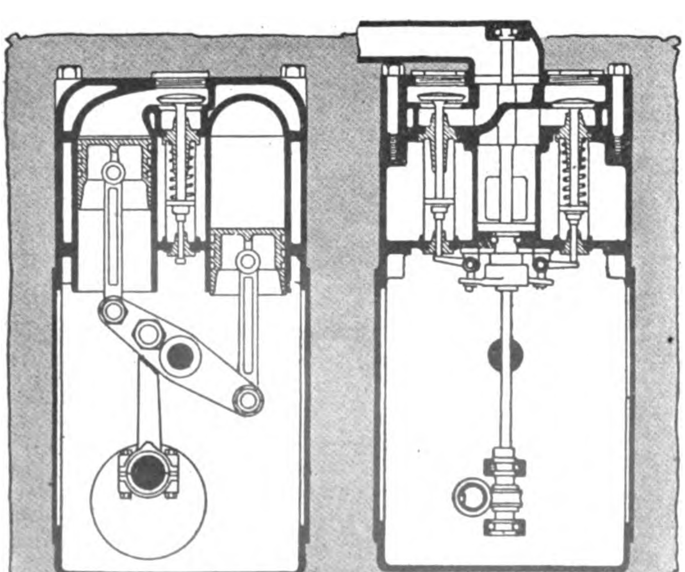

Fig. 10—Banner four-cylinder motor with central rotary valve

Keeping the valve at low temperature, without striving particularly after low bearing pressures or low circumferential speed; preserving the true shape of the valve by avoiding as much as possible the causes for its distortion, etc., are points well grasped and appreciated abroad. Accordingly the present state of matters is such that none of the American constructions offered has taken a firm enough hold in the trade to induce a single automobile manufacturer to adopt it for his product. On the other hand, constructions of European origin are not only in the hands of users abroad, but they even show a tendency to come on this market.

A question of interest is whether or not it should be feasible and practical to expect a rotary-valve system employing a barrel-type of valve to operate properly without some internal cooling. Internal cooling is not absolutely necessary, and constructions without it function well when properly designed. The leading representatives of motors with long cylindrical valves apparently neglected to work out their designs with due attention to the nature of the exterior valve cooling and the permanency of the shape of the bore wherein the valve operates; that and the sidewise spread of gases leave no other reasons which can be possibly given for the failures in this field. A close inspection of the conventional designs belonging into this group discloses certain interesting parts.

We have the liberty to indicate here merely one example with reference to the Mead construction, Fig. 8. In this motor the total explosion force acting against the cylinder top, extending practically from points A to B, is resisted by its flat cast-iron surface as wide as the valve ports, which are almost equal in length to the cylinder bore. The whole forms an arrangement subject to some deflection, as means for rigidity are omitted. This deflection would be greatest near the plane of the cylinder axis and passing through the middle of the ports. It will tend to lift the upper part of the valve housing from the valve surface, warping the rest of the bearing at the same time. This objection could be overcome by making a rigid top; it would be necessary, however, to consider the unequal expansion of a ribbed construction, which would be apt to show again some warping of the valve seat, though due to another reason. Shorter ports would help the matter considerably and the consequent decrease of their area could be compensated by making the valve of larger diameter, the latter alteration being quite practicable as there are comparatively well-functioning valves of diameters about equal to the cylinder bore. There is no reason to expect trouble in lubrication with the higher circumferential speed as long as the main harmful influences, heat and distortion, are eliminated. For this reason the particular construction, Fig. 8, and other similar ones should not be considered hopelessly impractical, but only insufficiently developed. It is difficult to see a reason for this lack of development since much promising work has been done with them.

No definite conclusion is to be taken as yet in regard to the advisability of straight cylindrical or tapered rotary valves. It was explained once that the cylindrical valve would be easier to fit to its seat with the specified amount of clearance by common manufacturing methods. Its running qualities could be impaired only when losing the original shape of its contact surface with the housing, which, by the way, has little chance to be caused through wear, the latter being negligible with proper care of the motor.

The tapered valve, on the other hand, was originated with the idea of regulating the bearing clearance and the wear, but it requires also more thorough means for its original good fitting to the shape of the seat; besides the wear which eventually might appear will be mostly concentrated in the surface of the valve seat opposite to the opening into the cylinder. Any wear on the valve proper is distributed over a larger surface passing opposite to the cylinder opening during the time of greatest pressure therein, thus both the valve and the seat when worn will assume an oblong irregular shape of section through their contact surfaces which no regulation by axial motion of the tapered valve could eliminate. **The aim of the tapered valve fails not only because the wear is negligible, but also because it cannot be taken care of properly by axial adjustment of the valve;** nevertheless some tapered valves are worth mentioning on account of special features, though nothing can be said at the present as to their practical value.

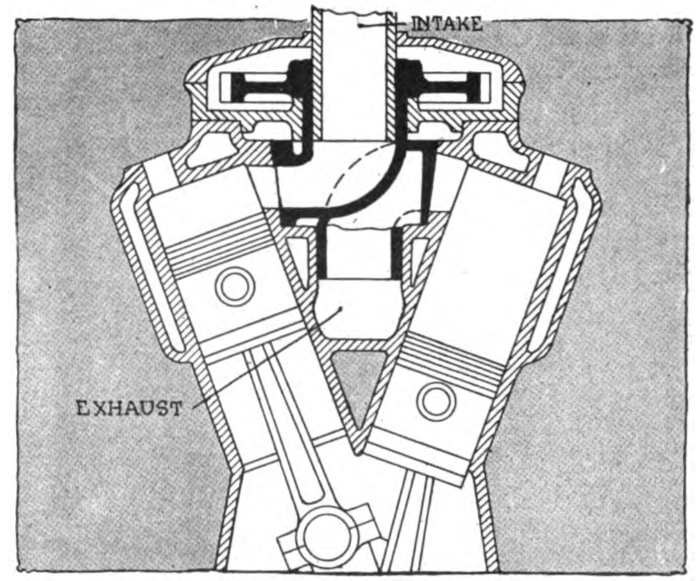

Fig. 11—Batzell tapered valve design for V motor

Fig. 9 shows the Silent-valve system, possessing an original driving method, which tends to free the valve from its seat as soon as any reason for tight running or sticking becomes noticeable. In theory the drive is simple and positive, but it is not free from practical defects, though the makers state that a relative motion of a fraction of a degree between the valve and its driving shaft is sufficient to lift the valve from its seat. This might be true only when the driving pin and cam surface are fitted close to each other. Some play between them would start in time and would be followed by change of timing in the individual cylinders. Should the amount of wear in the drive be great with a corresponding change of the timing, irregular motor running would result. The same can be expected due to untimely leaks from the cylinder, as could occur when the valve is somewhat listed from its seat during compression or explosion, when the chance of tight running is at its maximum. However, this valve looks operative notwithstanding that it has an irregular shape and expression, and that it is heated on a large surface by the exhaust gases.

The problem of satisfactorily driving the rotary valves, and the aim to eliminate all unnecessary complication in this

(*Continued on page 1327.*)

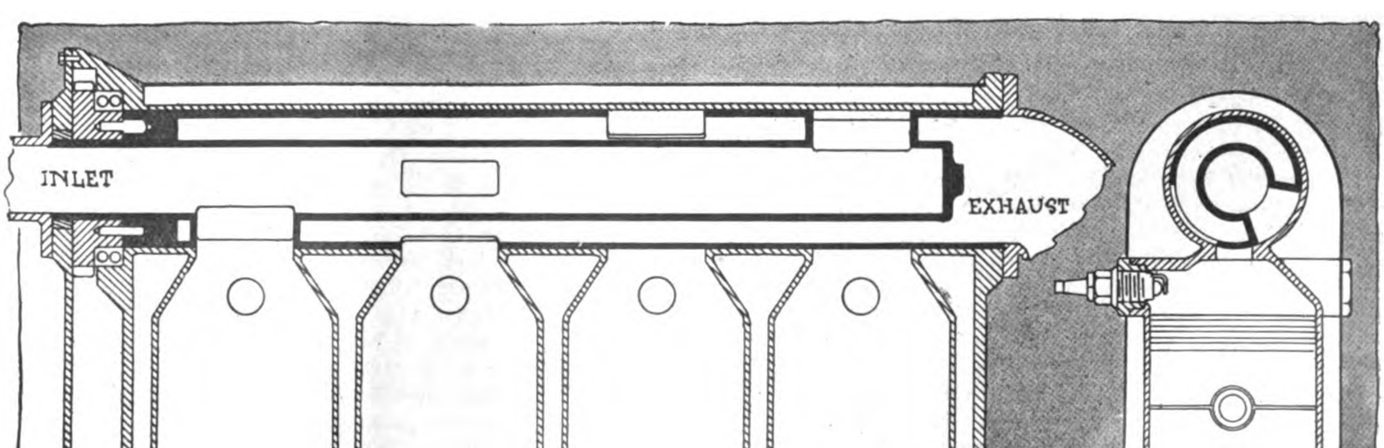

Fig. 12—Type of rotary valve which is subject to overheating with consequent tightening within the valve seat

Part IV Carburetion

by Robert W. A. Brewer

Subject Digest

Dugald Clerk discovered in 1907 that it was necessary to find out what was going on inside the cylinder in order to judge the performance of a carbureter, and in that year he read a paper calling attention to the value of exhaust gas analysis.

Exhaust gas analysis alone cannot truly determine how the carbureter is functioning at all motor speeds. It is extremely difficult in the first place to secure fairly average samples of gas on account of misfiring possibilities. This causes unburnt gas to mingle with the sample.

It was noticed in tests that when the CO_2 was allowed to increase to 11.6 that the load on the brake rapidly fell off and that the thermal efficiency was dropping rapidly.

Within considerably wide limits the richer mixture maintains the maximum horsepower at a constant value while the thermal efficiency drops off.

The most economical point to run is when the CO_2 is 13.5 per cent. by volume the O .2 per cent. and the CO is .7 per cent. to O. At this time the thermal efficiency was 26 per cent.

IN 1907 Dr. Dugald Clerk, who is probably the greatest authority on the internal combustion engine, read an important paper before the British Institution of Automobile Engineers on the principles of carburetion as determined by exhaust gas analyses.

He was thus the first to draw public attention to the importance of this method of determining what was taking place in the cylinders of an internal combustion engine. Previous to that time the Royal Automobile Club had been conducting some tests on motor cars, but did not previously make it clearly understood that exhaust gas analyses were going to be made. It was at that time generally thought that the emission of smoke only was to be judged upon. As a result of the findings of the committee it was a great surprise to the majority of automobile manufacturers to find how imperfect was their carburetion and there was a considerable outcry at the time. The modern conditions of high-speed motors make it extremely difficult to design a carbureter which will function throughout the prevailing ranges of load and speed, and by means of exhaust gas analysis are we able to determine what is taking place under various working conditions.

It must not be considered that by exhaust gas analysis alone can the true determination be made, and it is extremely difficult to obtain, in the first place, fair average samples of exhaust gases on account of the possibilities of misfiring, when charges are liable to escape and thus mingle with the sample of gases to be analyzed. This mingling gives a false impression, of course, as to what is actually taking place with regard to the products of combustion and any analyses must be considered only with considerable caution unless very great care is taken in sampling.

Dr. Dugald Clerk, himself, subsequent to the Royal Automobile Club experiments, made some experiments on an 18-horsepower car fitted with a four-cylinder engine. The gases were analyzed by Horatio Ballantyne, to whom reference will be made later on.

In this case exhaust samples were taken as follows:

1—The car standing on the level with the engine running as slowly as possible.

2—The car still standing on the level and the engine running at about 600 revolutions per minute.

3—The car running on the level at about 18 miles per hour, the throttle being one-half open.

4—The car climbing a hill, the engine running at 1,000 revolutions per minute and throttle from three-quarters to fully open.

A brief summary of the results obtained showed how erratic may be the products of combustion with ordinary working conditions. It will be noticed that these results are bound to differ from the laboratory tests where special care is taken to prevent anything occurring which might prejudice the results obtained.

As a result of these tests and subsequent experiments, Dr. Dugald Clerk is of opinion that **the erratic behavior is due to the lack of homogeneity in the mixture and this opinion is borne out by the writer, who has conducted a large number of experiments on exhaust gas with four-cycle and two-cycle motors,** and in his investigations has found the erratic behavior such as has been evident with Dr. Dugald Clerk's car.

Professor B. Hopkinson, Cambridge University, about the same time made a number of experiments upon this subject, and his results were embodied in a paper read before the British Association in 1907. These experiments were made on a four-cylinder Daimler engine, with cylinders 3.56-inch bore by 5.11-inch stroke, and the engine was run under full load at a constant speed at 750 revolutions per minute; but the Hopkinson tests are particularly interesting in this respect: They show that the percentage of CO_2 mounts from 10.9 to 13.5 per cent by volume as the horsepower of the engine increases to its maximum, and at the same time the thermal efficiency of the engine increases up to that point.

Above that point and onward as the percentage of CO_2 falls from 13.5 to 9.6, the brake load curve is practically flat, and is at its peak. During this period it is interesting to note that the percentage of CO_2 varies from 0.2 to 0, and the percentage of CO which was previously 0 quantity increased from 0.7 to 6.25.

As the percentage of CO_2 was allowed to increase up to 11.6 the brake load rapidly fell off, the whole of this time the thermal efficiency of the engine was dropping rapidly.

It will be seen that within considerably wide limits a rich mixture of fuel maintains the maximum horsepower at a practically constant value, whilst the thermal efficiency drops off, and that the most economical point to run is when CO_2 is 13.5 per cent. by volume, the O_2 is 0.2 per cent, the CO is 0.7 per cent. to O. At this time the thermal efficiency of the engine was 0.26 or 26 per cent.

Now when we come to compare these figures with those obtained by Dr. Watson in his paper on Thermal and Combustion Efficiency, we find that the most efficient all-round mixture **was obtained when the ratio of air to fuel by weight was from 15 or 16 to 1. At this time the thermal efficiency showed 0.249 or practically 25 per cent., and the**

mean effective pressure in the cylinder varied from 81 pounds per square inch to 84 pounds per square inch.

As the mixture's strength was weakened and the ratio of air to fuel by weight mounted to 18.7 to 1, the thermal efficiency dropped to 0.230 and the mean effective pressure to 65.4 pounds per square inch.

On a further weakening of the mixture until the ratio was 19.4 to 1, the mean effective pressure dropped further to 55.4 pounds per square inch and the thermal efficiency to 0.196.

Now, when we look to the other end of the scale and strengthen up the mixture we find that in Dr. Watson's tests as the ratio of air to fuel increased to 12.3 to 1 the mean effective pressure increased slightly up to 85.7 pounds per square inch, with a dropping thermal efficiency to 0.208, and as the mixture strength further increased to 11.7 to 1 the mean effective pressure dropped slightly to 85.6 pounds per square inch and the thermal efficiency dropped to 0.173.

Coming nearer home it is interesting to compare these figures with those obtained by Herbert Chase at the laboratory of the Automobile Club of America, and these figures are embodied in his paper read before the Society of Automobile Engineers at the summer meeting, 1912, and were at the time criticized by the writer. Mr. Chase's figures clearly show that he never reached the maximum thermal efficiency obtainable in an engine of this type, as the weakest mixture which it appears he used was 14.2 to 1, of air to fuel by weight, and at this proportion he obtained some of his best results, in which the CO_2 stood at 11.0 per cent., the CO at 2.4 per cent., and the O_2 at 0. These figures show that there was insufficient oxygen present to totally consume the CO to CO_2, and throughout the whole range of tests there appears to be the presence of CO in the exhaust gas analysis, which, of course, can be eliminated by a more satisfactory carburetion.

Mr. Chase's figures, being almost entirely of a mechanical nature, apart from a physical one, give the thermal efficiency rated on the boiler horsepower and the thermal efficiency at this mixture is 17.8 per cent. An elementary calculation will convert this to bring it into line with the thermal efficiencies previously given which are, of course, worked out on the indicated horsepower.

Throughout the whole of Mr. Chase's figures we find that the same somewhat erratic behavior is evident, to which reference has already been made. For instance, comparing his tests 25 to 27; in the former we find the ratio of air to fuel by weight 10.6 to 1 and the percentage of CO was 7.8, then in No. 26, where an increase of air supply is shown to 12.5 to 1, the CO dropped to 5.5 per cent., but with a further reduction of air supply to 11.9 to 1 there is also a reduction of CO which is contrary to what one would expect, and, furthermore, with this reduced air supply we find a trace of O_2 in the exhaust gas analysis.

These results can only be accounted for by a lack of homogeneity in the mixture, and are contrary to all expectations. It is evident, therefore, that too much reliance cannot be placed upon exhaust gas analysis alone, but this system of testing is very useful in conjunction with other observations.

The writer has found the exhaust gas analysis very useful in connection with the development of two-cycle motors, as when a carbureter is known to give certain results with a four-cycle engine, and is placed upon a two-cycle engine, the exhaust gas analysis gives some indication as to the amount of unburnt charge passing down the exhaust pipe and the excess of air necessary to give the best results.

Detecting Water in Petroleum Products

From Technical Paper 25, issued by Bureau of Mines, Department of the Interior, by Irving C. Allen and Walter A. Jacobs

WATER in a lubricating oil sometimes forms emulsions which tend to lower the durability of the oil and render it less efficient as a lubricant. In fuel oils the unfavorable effect of water is even greater. When burned in an internal-combustion engine it will be even more unsatisfactory. A drop of water may prevent ignition of the fuel.

Methods employed for the determination of water in petroleum and its product may be classified as follows:

1. Ascertaining the loss of weight by heating.
2. Diluting with a solvent and separating by gravity.
3. Diluting with a solvent and separating with a centrifuge.
4. Treating with calcium carbide.
5. Treating with sodium.
6. Use of a color-comparator tube.
7. Treating with normal acids.
8. Electrical treatment.
9. Distilling with a non-miscible liquid.
10. Directly distilling off the water

Method 1 is approximate and applicable to heavy oils and greases only.

Method 2 is approximate and applicable to thin oils. A diluent is to be avoided.

Method 3 is like 2 but more rapid, and somewhat more accurate.

Method 4 is convenient, and with petroleums, accurate to approximately 3 per cent. of the water percentage.

Method 5 is convenient and accurate.

Methods 6 and 7 are approximate only.

Method 8 is successful in breaking up an emulsion on a commercial scale or in reducing the water content of an oil to such a condition that it can be successfully treated in some other manner.

Method 9 is accurate to approximately 0.033 gram of water per 100 c. c. of benzene and oil in the distillate.

Method 10 is convenient, and can be used simultaneously with a distillation. It is accurate to about 0.003 gram of water in the distillate if the water is cooled to about 2 degrees C. Methods 5 and 10 may be described:

Treating with Sodium

Graefe estimates the water content of an oil by agitating with finely cut metallic sodium. This process may be carried out as follows: For each gram of water in the sample of oil, about 2 grams of finely cut sodium is used in the same apparatus and in exactly the same manner as described in method 4. The reaction will be as follows:

$$Na_2 + 2H_2O = 2NaOH + H_2$$

or 1 gram of water will generate 2-36 gram of hydrogen.

One thousand cubic centimeters of hydrogen weigh 0.09004 gram at 0 degrees Centigrade and 760 millimeters pressure, or 1 gram of hydrogen has a volume of 11,106.17 cubic centimeters. One gram of water generates 2-36 × 11,106.17 cubic centimeters, or 617.0095 cubic centimeters of hydrogen; or 1 cubic centimeter of hydrogen represents 0.00162 gram of water in the sample used.

Distilling Off the Water Directly

Bell, Senger, and Allen distill the sample directly, and measure or weigh the quantity of water that settles in the distillate. The water content may be accurately and conveniently determined during the course of an ordinary distillation in the following manner: Two hundred grams of the sample is weighed into a .25-liter-distilling flask and the distillation carried out in the ordinary manner at the rate of one drop of distillate per second. The distillation can be performed most accurately in an electric still. At temperatures between 90 degrees and 150 degrees Centigrade, the water distills over, and can be removed from the receivers by means of a micropipette and weighed. Usually a few drops of water adhere to the condenser, and fail to run into the receivers; in this event a small pellet of absorbent cotton, moistened with water, squeezed as dry as possible, and weighed, is fastened to a wire and run up into the condenser to remove these last traces of water. The amount of the increased weight of the cotton pellet, reckoned as water, is added to the weight of the water in the receivers.

Definition of Mechanical Fits—Caring for Storage Batteries in Winter—Use of Tire Preservers—Poor Compression Causes Power Loss—Where Carbon Forms—Easing a Cone Clutch—Trouble With Wheel Bearing

Mechanical Fits of Many Kinds

EDITOR THE AUTOMOBILE:—How many fits are there used in mechanics? I have heard of driving fits, sucking fits and loose fits, and also other kinds of fits. I would like to know if there is any definite meaning attached to these terms.

New York City. CHARLES P. RUPPERTS.

—According to accepted practice there are four general classifications of fits, namely, force fits, driving fits, push fits and running fits. Running fits are divided into three sections known as easy fits, close fits and fine fits. Force fits are used in places where the parts are never intended to be taken apart again, such as where rear axle housings are formed of tubes pressed together under hydraulic pressure. Driving fits are used in parts where close adherence is a necessity, and where the parts are to be disassembled by the use of an ordinary hammer. Examples of this type of fit are found at flywheels, gearwheels, ball bearing inner races and generally devices which are fastened by tapered keys. Push fits are used in such places where the parts do not have relative motions in actual work, but which have sufficient freedom to be assembled by hand. This is true of bolts, slip joints, ball-bearing outer races, etc. Running fits are used in places where parts have relative motion. They are subdivided as stated above, and are used as follows: Easy fits: where great freedom of running is required and where lubrication is not copious. This is true of valve guides, control connections, clutch shafts, etc. Close fits: used in all high-speed work, and found in ordinary bearings. Fine fits; used in all parts where the stresses are of an alternating or vibratory nature, and where great accuracy is required. Lubrication should be copious to these parts.

Winter Care of Storage Battery

Editor THE AUTOMOBILE:—We do not put our cars out of commission here in South Carolina during the winter as the bad weather does not last many weeks at a time. It has only been necessary for the car owner to drain the radiator when he comes in, in expectation of a cold night, but now we have the storage battery to protect. Will you give us information through THE AUTOMOBILE how to do this?

2. Does it take more horsepower to pull a car when the chains are on?

Inman, S. C. G. C. F.

—When the car is standing in the garage there is no danger of the solution freezing when the battery is fully charged unless the temperature gets as low as 20 degrees below zero. When not fully charged, however, the danger is great, as it may freeze a few degrees below freezing point if nearly discharged. If the car is not to be used in winter, keep the battery fully charged at all times. In running the car, the battery should be protected so that the wind cannot blow against it.

2. It requires a slightly increased horsepower, although the increase is so slight as not to be noticeable. It may be made apparent by trying to push the car with the chains on.

Use of Tire Preservers

Editor THE AUTOMOBILE:—Will you please tell me if the various compounds for preserving tires really rejuvenates the rubber, as some of these makers claim, or merely act in the same way as paint?

New York City. J. E. S.

—So-called tire rejuvenators are no doubt of great value as far as appearance goes and also are of some use in forming a protecting film over the rubber at such points where it is not rubbed off by contact with the ground or other points, but are useless as far as actually rejuvenating the rubber is concerned. When rubber is once rotten, worn out or otherwise decayed it is impossible to bring it back to its former stage. It may, however, be mixed to a certain percentage of pure rubber and fair results obtained, although this practice does not give nearly the results as compared with pure rubber.

Motor Losing Power Rapidly

Editor THE AUTOMOBILE:—Lately my motor has failed to deliver the power which it formerly possessed. I cannot climb hills or make the same speed on slight inclines as I formerly could. What do you think would be the cause of this? The ignition is good, and the motor never misfires.

Beloit, Wis. T. A. C.

—One of the chief causes of the loss of power is poor compression. Another great cause is that the mixture is either too lean or too rich or very often bearings are so tight that the increased friction will cause a considerable loss of power. Outside the motor a slipping clutch or dragging brake will cause a falling off in the pulling capacity of the motor. Low compression means absence of an explosive mixture in the cylinder. It may be determined by turning over the motor by hand and noting if the resistance to turning is light or heavy or if it is the same in all cylinders. Sometimes a motor will lose compression after it has been started, and in this case it will begin to misfire and finally stop altogether, or else run very slowly. Low compression may be due to a leak in the combustion chamber through the various joints which lead to it, such as the threads around the spark-plug or valve cap through the bushings surrounding the valve stems owing to a sticking valve, pitted valve, weak spring on the exhaust valve, loose or open compression cup, leaky piston, defective gasket in the cylinder head or other cylinder connections, a broken valve or valve stem, a scored cylinder wall, or a bady adjusted valve which is held off the seat when the motor is at rest or cold. Leaks through the different joints may be detected by the application of a little soapy water or oil to the suspected points. If there is any leakage it will be indicated by the formation of bubbles. A leaky piston can be detected by a sharp hiss within the cylinder, while a broken ring will give the same indication. Occasionally the openings of the circumferences of the piston rings get into line and allow the gases to escape. This can be found out only by removing the piston and is easily remedied by turning the rings so that the openings in their circumferences are staggered. Sometimes a valve will not be able to close because a piece of carbon has become lodged on the seat or when the valve is broken or cracked a leak will be caused. Carbon also very often works its way into the piston rings and causes them to stick so tightly that they are bent out of shape and spoil the cylinders. Scored cylinders are caused by a variety of things, the principal one being insufficient lubrication. The cure is in having the cylinders rebored. A slipping clutch is a great absorber of power and is often very deceptive, causing the owner to believe that it is the motor which is at fault instead of the clutch. A slipping clutch may be cured, if it is a cone by the application of gasoline to the leather, a treatment of neat's-foot oil, or an increase of tension on the clutch spring. If it is a multiple-disk clutch a thorough cleaning with kerosene will generally restore it to its former condition. Dragging brakes absorb power and cause the motor to overcome a large amount of resistance which is unnecessary. Dragging brakes may be detected by jacking up the rear wheel and revolving it, noting the resistance. It may be cured by changing the adjustment on the brakes so as to remove friction.

Trouble with Front Wheel Bearing

Editor THE AUTOMOBILE:—I am using a Hupmobile 20-horsepower runabout and while running slowly the other day heard a clicking and grinding noise from the front wheel on the right side. On examination I found that the hub cap on that wheel was all splintered to pieces, and when removed fell apart. I also found that the part upon which the hub cap screwed was also cracked and this was what caused the breaking of the hub cap. On trying the front wheel I found that there was a great amount of play. As I was in a hurry at the time I simply screwed the cone up tightly against the balls taking up the play, but I had not gone but a short distance when I heard a sound and looking down found that all the balls had dropped out and that the ball race was ground to pieces. I was forced to go home on the damaged wheel, and had to travel a distance of about 50 miles and found that the spindle had been sawed through by one edge of the ball race, and it cost me $14 to repair the damage. Would you tell me what could have been the cause of the trouble and whether it was something I could have guarded against by taking due precautions?

New Rochelle, N. Y. M. M.

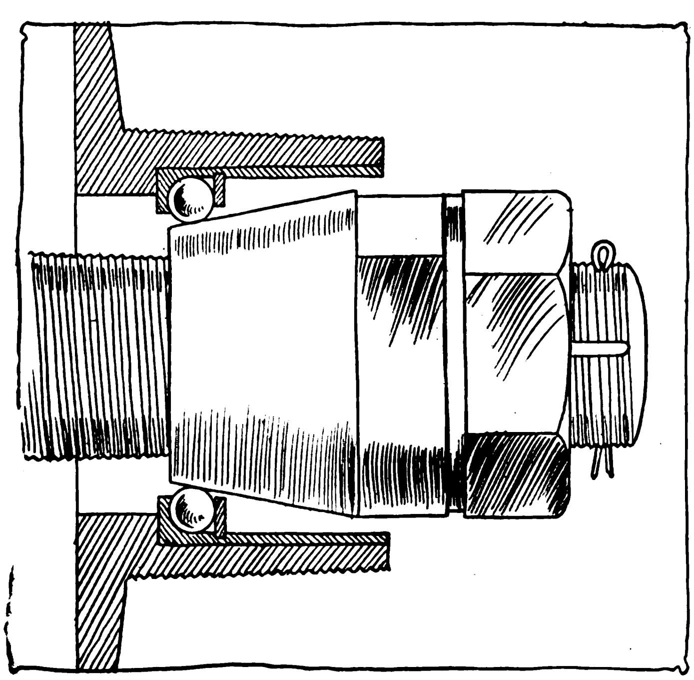

Fig. 1—Relative arrangement of parts in an ordinary cup and cone bearing such as used in small runabouts for the front wheel outer bearing. Bearings of this type require occasional adjustment

—The trouble was that you did not keep an eye on the front wheels in order to take up the play when it became excessive. As shown in Fig. 1, the cone enters the circle formed by the ring and ball bearing and the balls run between the race and the cone. After a time it becomes necessary to take up the play in this type of bearing. If this is not done the wheel is allowed to slope upwards, and carrying the raceway with it furnishes an irregular surface for the balls to run upon. The result is that the raceway is worn and also the cones, thereby giving a rough surface which will wear the balls as well as the bearing surfaces. The relationship of the parts under these circumstances is shown in Fig. 2, and this condition becomes worse and worse until finally the raceway bears on the spindle and begins to cut through it. The way to guard against this is by taking up on tht cone whenever the play becomes excessive.

Points Where Carbon Deposits

Editor THE AUTOMOBILE:—Is it necessary in going over a car that is giving satisfaction to remove carbon from the cylinders when there has been no indication up to the time that the car is to be put away that there is any carbon trouble? Time is no object, but I do not wish to enter upon a task which will be of no use after I have finished it. What are the usual points of carbon deposit, what is it due to, and what damage can its presence cause?

Elizabeth, N. J. CARBON.

—Carbon trouble is one of the recurring annoyances of automobile motors which has never been entirely removed. The heat of combustion is so high that even the best of oils leave some deposit. This may be so small that it is not noticeable after an entire season's use, but, on the other hand, it might be so great that the motor refuses to function as it should. When going over the car during the winter, it would be best to thoroughly clean the cylinders of all traces of carbon. Referring to Fig. 5, the usual point of carbon deposits will be noted. On the piston head a formation will also occur which takes the shape of a cone. This cone is gradually built up higher and higher as the deposits go on until finally it accumulates to such an extent that the apex of the cone has removed for some little distance from the metal of the piston. When it reaches this condition it becomes incandescent, and the point starts to glow. The result is that the highly compressed gases are exploded before the piston reaches its upper dead center, and the effect is the same as if the

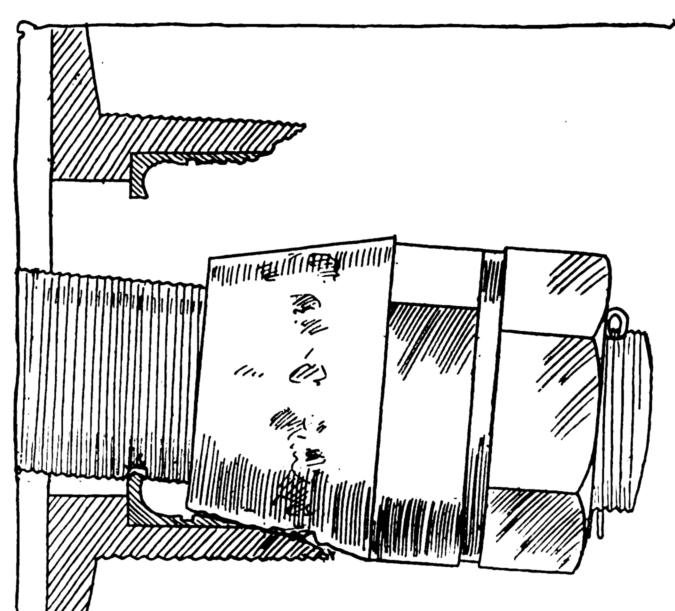

Fig. 2—Condition bearing may reach if not adjusted. Balls have dropped out and wheel is rusting on hub ball race cutting into wheel spindle. This condition actually occurred on a car brought to the attention of The Automobile recently

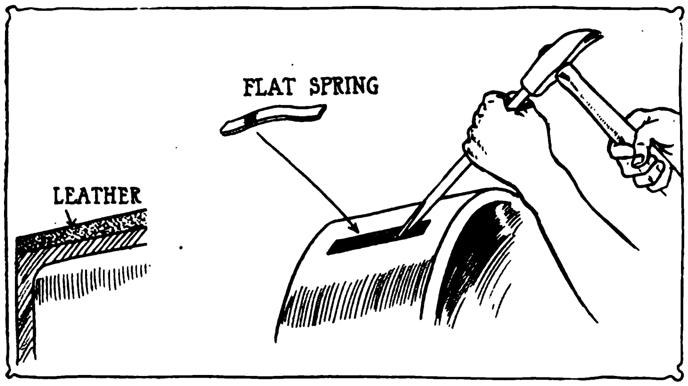

Fig. 3—Showing how clutch may be repaired for flat springs beneath leather

spark had been advanced too far. A knock of considerable force is heard and the mystified driver is often inclined to believe that there is a loose bearing somewhere in the motor. The same applies to the carbon deposits which form on other exposed points in the combustion space. Another point where carbon deposits are apt to gather and cause considerable trouble is on the electrodes of the spark-plug. This cuts off the spark and results in the cylinder being a load instead of a function of the propulsive effort of the motor. When the carbon deposit gathers on the valve seat it prevents the valve from closing, and hence cuts down the compression in the cylinder to which the valve belongs and deprives it of nearly all its power.

Use of Carbon Remover

Editor THE AUTOMOBILE:—I have recently purchased a can of carbon remover upon which there were no directions as to how to use it. The can has been lying around the garage for several days, and now when I want to use it I find that even the label giving the directions and the name has been destroyed. It is a liquid substance about the consistency in color of maple syrup with a very strong pungent odor. Would you tell me how these carbon removers are generally used, and if they are safe?

Denvel, Col. L. P. MOORE.

—In general it may be stated that the patent removers on the market are very good. They are strong solvents, and do not hurt the metal of the cylinder in any way. On the other hand, however, there are some which are not as good as they should be, and it would be well before using something which you know nothing about to secure another can of carbon remover of some well-known make. The 75 cents extra or thereabouts is not worth the risk which you would be under when using a fluid with the nature of which you are unacquainted. In general, these carbon removers are used as follows: The spark-plugs are removed and the remover poured into the cylinders so that about a half pint will be distributed between four cylinders. It is left standing a few hours and then blown out by turning over the motor with the relief cocks open. After this the motor is started and run until it stops smoking at which time the carbon is supposed to be out of the cylinder.

Adjusting the Marathon Clutch

Editor THE AUTOMOBILE:—I have a 1912 model M-40 Marathon and wish to adjust the clutch, which is dragging. Will THE AUTOMOBILE kindly explain how this should be done, showing the working parts of the clutch? Might add that I have given it a thorough cleaning with coal oil and gasoline, but it still drags.

Neche, N. D. A SUBSCRIBER.

—The Marathon clutch is of a multiple-disk type and is housed within the same casing as the gearset. It consists of twelve saw-steel plates running in oil and is supported by two bearings. Three strings are provided on the clutch and adjustment may be made through the handhole on the gearset housing. The clutch was depicted on page 1278 of THE AUTOMOBILE for December 19. The nuts at the head of each spring controlling the tension may be reached through the large cover plate over the gearset housing. By backing these nuts the tension on the springs will be decreased sufficiently to prevent the clutch from dragging if this is the cause. Should the plates not be clean a treatment of kerosene should remedy the trouble.

Pennsylvania Parts Wanted

Editor THE AUTOMOBILE:—Do you know of any available parts for a model B 27 Pennsylvania car, manufactured by the Pennsylvania Auto Motors Company, Bryn Mawr, Pa., now bankrupt and out of business? Also advise me if possible by whom the rear system and universal joint in this car were manufactured.

Mansfield, O. H. W. LUDWIG.

—Parts of this car can probably be secured from the Auto Parts Company, Detroit, Mich.

Easing Leather Cone Clutch

Editor THE AUTOMOBILE:—I am using a car which is fitted with a leather cone clutch. Unlike most clutches of this kind the one I have is very harsh. It is impossible to start the car off without a jerk, and no matter how I try I have great difficulty in getting under way without discomfort to the passengers. I have soaked the leather with castor and neat's-foot oils, but this does not afford any great relief. I am thinking of putting in cork inserts or some type of spring, and would like to know which you would recommend.

Birmingham, Ala. J. G. H.

—The methods which you suggest are both good, but that in which springs are used is a little simpler to apply than the other. Fig. 3 shows how this may be done. The metal beneath the leather is grooved for a distance a little greater and the thickness of the metal of which the spring is composed. The spring is shaped as shown in the illustration, and is placed in a groove which is of such length that the spring may be flattened within

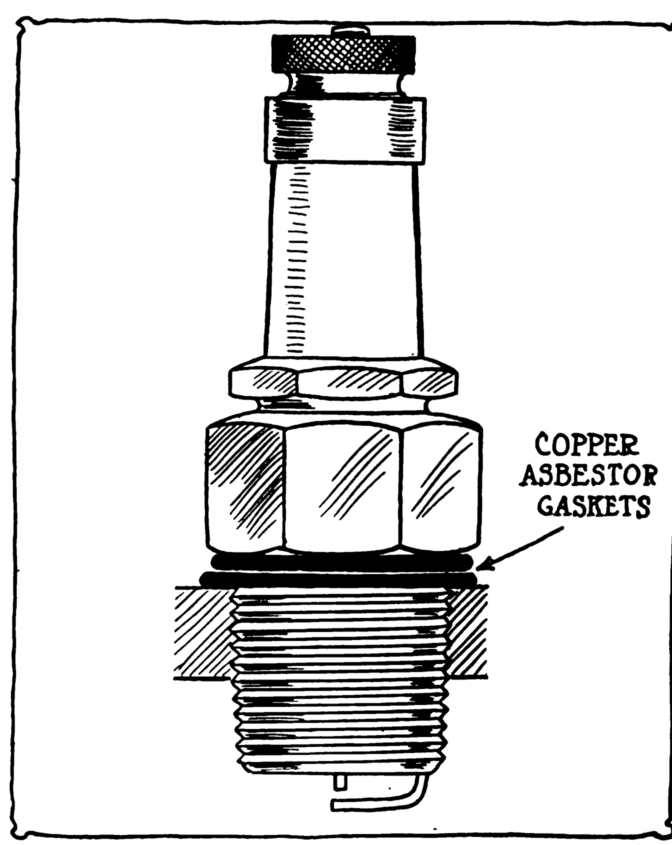

Fig. 4—Use of two copper asbestos gaskets will prevent leaks at plug

it without making a groove or a lump in the leather when the latter is placed over it, and the clutch is engaged. This cure should help your troubles and do away with the harsh engagement of the clutch. There is a possibility that the tension on the spring is too strong or that the motor misfires at low speeds, making it necessary to speed up to such an extent that the car starts off with a jerk.

Two Magnetos as Stock Equipment

Editor THE AUTOMOBILE:—Kindly advise me if any company ever made stock cars with two magnetos as regular equipment, and, if so, what company?

Lincoln, Neb. LLOYD JORDAN.

—Although two magnetos have often been put on racing cars they have never been given as standard equipment. It would be a waste of money and space to so equip a car as it would be perfectly possible to secure two-point ignition from a single magneto which had been designed for that purpose. A magneto so seldom goes wrong that the batteries which are used for starting purposes are sufficient protection against an emergency.

Advantages of Fixed Spark

Editor THE AUTOMOBILE:—I see that on some of the cheaper cars fixed spark is used. I am driving a small runabout which has a variable spark and would like to know why the fixed spark is adopted on some of these cars. I do not see how it can be economical at all speeds. Would you please tell me through THE AUTOMOBILE what are the advantages.

Huntington, L. I. G. C. TYLER.

—The fixed spark is only an advantage in so far as its cheapness and simplicity are concerned. For economy it is greatly surpassed by either the automatic advance or the variable spark. There is one point at every engine speed at which the spark should occur to secure the greatest economy. This is at the greatest possible advance. Every fraction of the stroke that the spark is delayed after this means so much falling off in efficiency, and a greater increase of unburned products in the exhaust. The spark should always be advanced as far as it can be without closing a notch due to too early ignition. It is, of course, impossible to secure this condition at any but one speed with a fixed spark. For the variable spark this can be secured at any speed when under the control of an experienced driver. The only reason the fixed-spark magneto is used is that, although the utmost economy cannot be secured with it, the results are uniformly good and it is cheap without introducing any added complications. Automatic advance is equally simple so far as the driver is concerned and gives a much greater economy than the average driver obtains with a variable spark.

Use Correct Size Carbureter

Editor THE AUTOMOBILE:—Please let me know what size model L Schebler carbureter will give the most power, that is, the correct size for a single-cylinder automobile engine, bore 5 inches, 6-inch stroke, four-cycle; average speed about 400 revolutions per minute to 600 revolutions per minute. After getting the correct size Schebler carbureter, would any other make of carbureter be correct in using same size for the same engine?

Dawson, Minn. G. O. HELVIG.

—A 1.5-inch carbureter would be the best to use on your motor. Carbureters run about the same size, so that any other 1.-5-inch size carbureter would suit your motor. A good formula for determining the correct size carbureter to use on any motor is:

$$\text{Size in inches} = \sqrt{\frac{D^2 \times S \times R}{C}}$$

In this formula D is the diameter of the cylinder in inches, S the stroke, R the revolutions per minute, and C a constant which is equal to 50,000 for automobile motors of the four-cycle type. This formula is approximate and may be used irrespective of

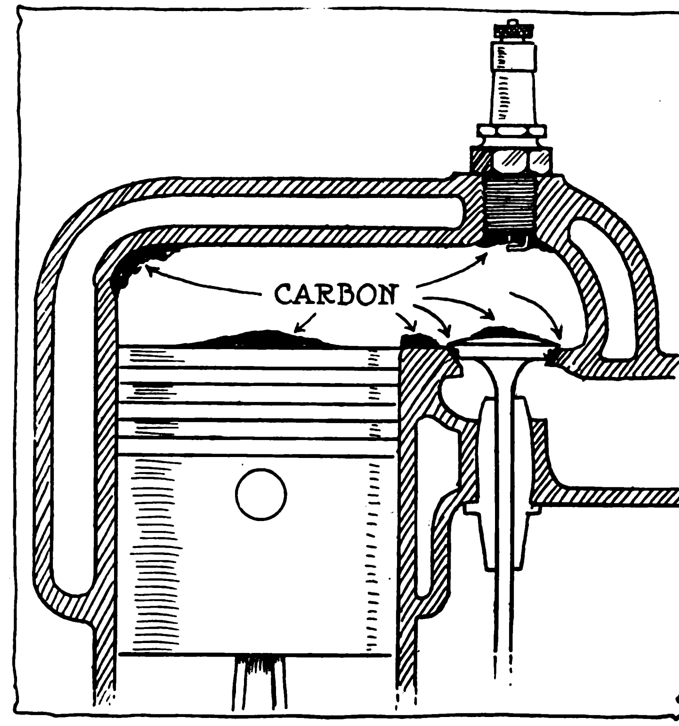

Fig. 5—Showing points in cylinder where carbon deposits are apt to gather

the number of cylinders on the motor. This is true for the reason that even in motors of six cylinders the suction strokes do not noticeably overlap each other.

Suggests Garageman's Commandments

Editor THE AUTOMOBILE:—I am sending a set of commandments for the garageman for publication in THE AUTOMOBILE. I have been in the automobile business for a number of years and believe there is more truth than poetry in these commandments:

1.—Thou shalt not talk of any other garageman before me.

2.—Thou shalt not expect the garageman to keep his place open till the cock crows in the rosy morn, so that thy machine will be safe from storm and thieves without giving him a piece of money.

3.—Thou shalt not expect the garageman to perform miracles with thy machine when thou didst fail to put oil in the engine since last summer.

4—Thou shalt not tinker with the carbureter or magneto of thine automobile lest thy days of pleasure on earth be few.

5.—Thou shalt not take thy machine to the blacksmith for repairs for verily I say unto you the blacksmith straightway sends for the garageman to make the needed repairs, and thy bill is increased two-fold.

6.—Thou shalt not, when thou wouldst buy an automobile, go like a thief in the night to cities afar off in order that thou mayest save a few small pieces of silver, for surely the publican of the city will see thee coming.

7.—Thou shalt not if thou be a banker who loans other people's money at high rates of interest, take an agency, in order that thyself and thy wife's brother may get a machine at cost, lest likewise thy depositors take a notion to loan their own money, and thou wilt have more job than a rabbit.

8.—Thou shalt not after the garageman has risen from his bed at 2 a. m to repair thy broken-down machine which thou didst buy because it was cheap, deny and refuse to pay thy bill because there is a place where the worm dieth not and the fire is not quenched.

9.—Thou shalt not get wroth and curse the tire maker in thy wrath because thy tire blew up when thou kept only 40 pounds of air in thy tires when thou shouldst have had 80 pounds.

10—Thou shalt not tell the garageman that thou did not change the adjustments of the machine which thou didst buy of him, in order that thou mayest get him to work for thee for nothing, lest he smite thee in his just wrath.

11.—Thou shalt not covet the garageman's job, nor his bookkeeper, nor his stenographer, for verily his days are long and full of trouble, nor shalt thou covet his gasoline, nor his oil, nor his transmission grease, nor the labor of his mechanics, unless thou dost intend to pay for it.

Kewanee, Ill. GARAGEMAN.

Uses Two Copper Gaskets

Editor THE AUTOMOBILE:—I find that in order to stop a leak from around the sides of the spark-plug I am compelled to use two copper asbestos gaskets. These are placed as shown in the accompanying sketch, Fig. 4. This tip may be of use to some who hear a hissing sound from their cylinders.

Cornwall, N. Y. EDWARD BRONSVELD.

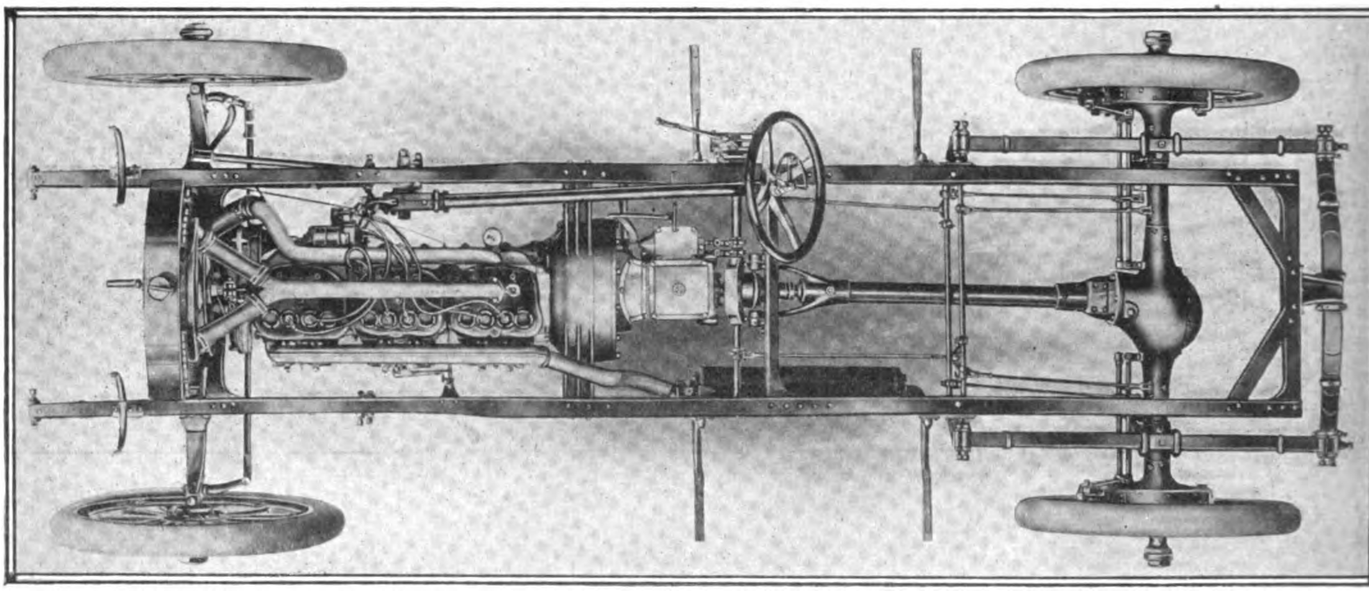

Fig. 1—Plan view of Havers 6-44 chassis, showing Y-shaped water outlet manifold and unit power plant

Havers Adds a Big Six

Continues 6-44 with Minor Changes—New 6-55 Has Larger Motor, Longer Wheelbase and Larger Body

North East Electric Lighting, Starting and Ignition System and Full Equipment Features of New Model

THE Havers Motor Car Company, Port Huron, Mich., will manufacture two chassis types and four body designs for the 1913 season. Previously only a single six-cylinder chassis has been marketed, on which a touring car and a roadster body were fitted. This is the model 6-44, which has been continued; the new model—also a six-cylinder machine—has a larger motor and is known as model 6-55. It is made with either a five-passenger touring car body or with a special speedster body.

A few refinements of detail have been made in the chassis of the 6-44. The new model is similar in general specifications to this earlier type, but, in addition to having increased horsepower, its wheelbase is longer, the touring car body is larger than that of the 44, and the equipment is complete. The latter item includes the North East combination electric lighting, starting and ignition system.

The unit power plant idea is embodied in the Havers designs. The smaller motor has a bore of 3.75 inches and a stroke of 5 inches, giving a rated horsepower of 33.75 S. A. E., while with dimensions of 4 by 5 inches, bore and stroke, respectively, the larger motor has a rating of 38.4 horsepower, S. A. E. formula. With this long stroke the motors are plainly underrated by the latter, and the factory ratings are set at 44 and 55 horsepower, respectively, as indicated by the model designations. The stroke-bore ratios are 1.33 and 1.25.

The cylinders are cast in pairs and are of L-head design, the valve stems and springs being completely inclosed by aluminum cover plates, as shown in Fig. 1. Valves are on the left side and have a diameter of 1 13-16 inches. The intake ports of each pair of cylinders have a common opening into the manifold, while there is an individual passage from each exhaust port to the exhaust manifold connection. This will be evident from an inspection of the motor illustrations.

The pistons are exceedingly long and are provided with oil grooves below the piston pins and bosses, which, together with

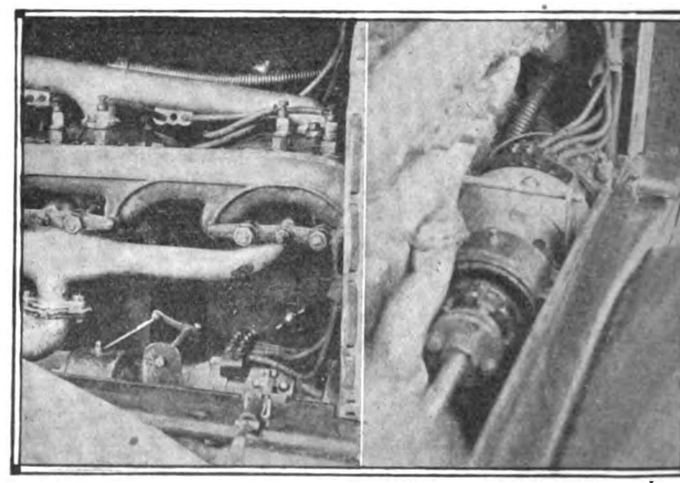

Fig. 2—Two views of the installation of the North East electric lighting, starting and igniting dynamo on the Havers 6-55

the relief holes, distribute the oil to the cylinder walls and aid in the escape of surplus lubricant. Each piston has three compression rings of eccentric design and with butt joints. The connecting-rods are drop forgings of liberal dimensions. They are provided with adjustable, die-cast, nickel-bronze split bushings at their lower ends, which are shimmed in place.

The crankshaft has four bearings, which are fastened to the upper half of the crankcase as in average practice. For the larger motor the bearing lengths are 4 inches for the rear, 3 inches for the two center and 3.5 inches for the front bearing. The lower connecting-rod bearings have a length of 2 5-8 inches. The flywheel bolts to a flange which is integral with the crankshaft. Like the crankshaft, the camshaft has four bearings, which are of ample size. The cams are forged integrally with the shaft. Timing gears are of the helically cut type and of steel.

The lubrication of these motors is accomplished through the use of a combined force-feed and splash system. The oil is forced by a gear pump from the reservoir, which is cast integral with the lower half of the crankcase, through a distributing channel in the upper half of the crankcase to the main bearings and to the gears. Grooves carry the excess oil from these points to the oil troughs, where it is dipped up and splashed to all parts of the motor by the connecting-rod ends. There is an individual trough under each connecting-rod. The oil eventually finds its way back to the reservoir, from which, after being strained, it is again conveyed to the main bearings and gears.

The cooling is by the thermo-syphon system, no circulating water pump being employed. There are two connections from the water outlet manifold at the top of the cylinders to the radiator, forming a Y, as may be seen in the plan view of the chassis, Fig. 1. The radiator is of the cellular type. The water jacket space around the cylinders is .75 inch thick. Cooling is aided by the ordinary type of fan between motor and radiator, driven from the magneto shaft by a belt. There is an adjustment for tightening the fan belt. Water enters the cylinder jackets at the right side of the power plant.

The two models differ in the type of ignition used, model 6-55 making use of a combined starting, lighting and ignition system which is the product of the North East Electric Company, Rochester, N. Y., while the 6-44 utilizes the Bosch dual system, an acetylene starter being fitted as part of the regular equipment. The magneto, which is carried on a bracket integral with the upper half of the crankcase, is gear-driven from the crankshaft through a magneto shaft in the usual way.

The generator-motor of the 6-55 is carried on the opposite side from that of the magneto on the smaller engine, as will be evident from Fig. 2, which shows the generator-motor on the intake side and at the rear so as to be close to the flywheel, to which it is geared. In connection with the system a storage battery is used, as well as starting and lock switches. The storage battery performs the usual function of furnishing starting current, driving the motor-generator as a motor and revolving the crankshaft. The battery, which is the recipient of all energy generated in excess of that needed for lighting and ignition, also furnishes current for lighting the lamps when the engine is running at a speed too low to cause sufficient energy to be generated by the motor-generator and when the car is not running. The generator has no governor or other device to regulate its speed, an automatic gear arrangement providing the proper gear ratio between motor and generator at all engine speeds.

The carbureter is of Stromberg make and is located at the center of the left side of the power plant. The fuel is carried in a 20-gallon tank under the seats, feeding by gravity.

The power from the motor is transferred to the transmission gearset through a multiple steel-disk clutch, alternate plates of which are lined with Raybestos. The gearbox bolts directly to the flywheel housing, as in accepted unit power plant design. Cover plates permit of free access to all the gearset mechanism. The transmission has three speeds forward and reverse and is of the selective type. The main driveshaft and the countershaft are carried on annular ball bearings. Gears are of chrome-vanadium steel, heat-treated and case hardened. They have wide faces and are of ample diameter.

Power is conveyed to the rear axle by a nickel steel driveshaft having a diameter of 1.5 inches. It is inclosed in a torque tube, which has two arms at its front end fastening to a cross-member of the frame, as shown in Fig. 1. The rear end of the tube bolts to the rear axle housing. One universal joint is found just back of the gearbox, where is also located a slip joint on the transmission shaft. The driving strain is carried through radius rods, while torsional strain is taken by the frame through the agency of a large yoke on the third member.

The rear axle is of the floating type, by which construction the weight of the car is borne by the axle housing, the driveshafts having only the function of turning the rear wheels. The differential gears are made accessible through a plate at the back of the housing. Brakes are of large size, the surface brakes contracting externally, while the emergency brakes expand within the drums. Both sets are equipped with equalizers, as shown in Fig. 1.

The front axle is of the drop-forged I-beam type, the yokes being similarly manufactured. The frame is of the so-called double-drop design, constructed of pressed steel of heavy channel section. Fig. 6 shows the first drop to be about opposite the flywheel, while the second is at the rear axle, as may be seen in Fig. 3. The front width of the frame is 30 inches, while it is 31.5 inches in the rear.

Springs are semi-elliptic in front and have a length of 40 inches. They are 2 inches in width. The rear spring suspension is of the platform type, that is, there are two half-elliptic side springs and a cross-spring in the rear, as will be seen from the

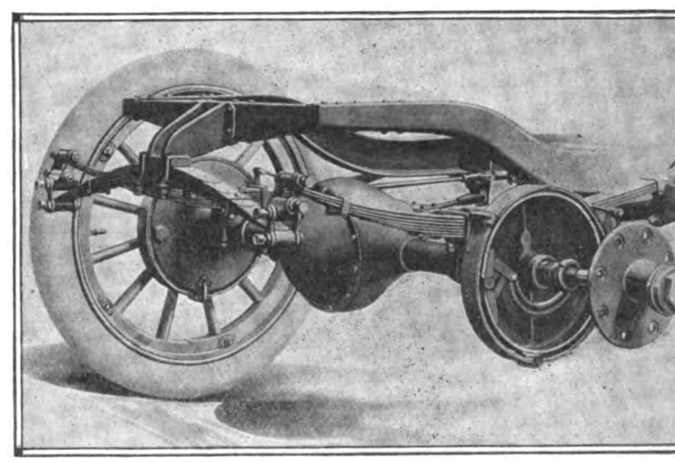

Fig. 3—View of the rear construction of the Havers, showing platform spring suspension and rear axle design

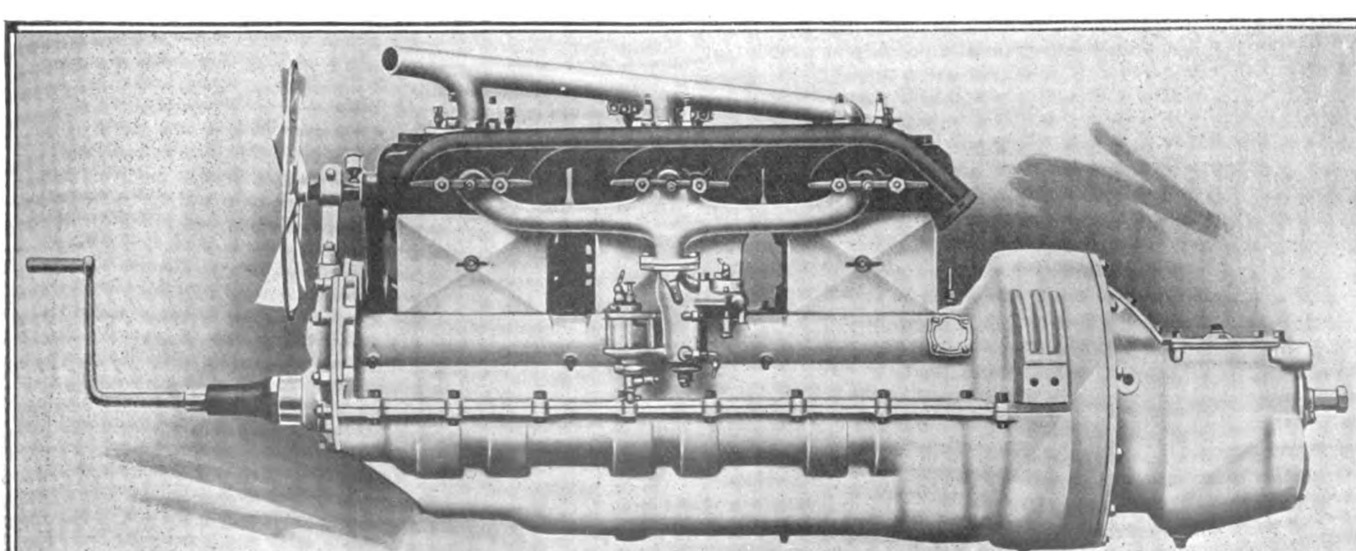

Fig. 4—Side elevation of unit power plant of the Havers 6-44, intake side. Note cover plates inclosing valves

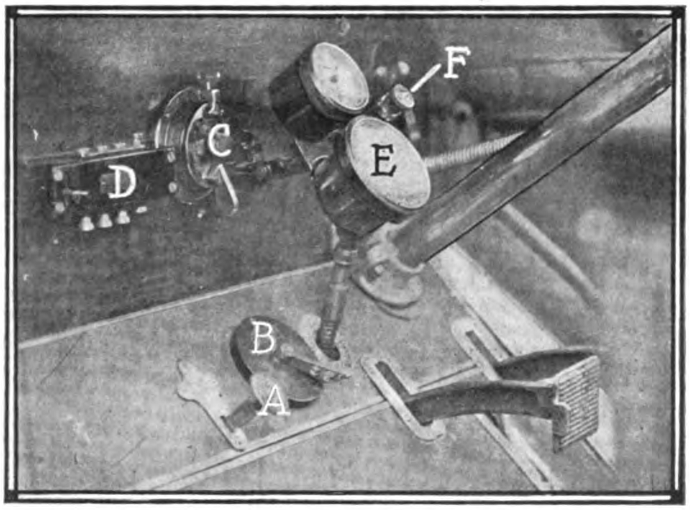

Fig. 5—Havers dash for 1913, showing control features

plan view of the chassis, Fig. 1. With this construction the rear of the frame is really suspended at three points, which is claimed to be as much of an advantage as the three-point suspension of the power plant, in that inequalities of the road surface are taken care of without straining the springs or frame in any way. The rear side springs are outside the frame, but shackle to it only at the front ends, their rear ends fastening to the ends of the inverted rear cross-spring, which is rigidly secured at its center to the rear cross-member of the frame. These rear springs have dimensions of 36 by 2 inches.

The wheels are of the wood artillery type, with large hubs and heavy spokes, of which there are twelve both front and rear. These wheels take either Baker or Firestone demountable and detachable rims, the make being optional with the purchaser. Tires are 36 by 4 inches all around. The wheelbase of the 6-55 models is 128 inches, while that of the earlier type is 122 inches. The tread is standard.

The control is on the right, the gear-shift and emergency brake levers being at the driver's right, but inside the car body. The steering gear construction is of the worm and gear type, making possible the simple adjustment for wear. The steering gear is irreversible. The steering column is of nickel and has a diameter of 1.75 inch. The control is standard in all its features, consisting of brake and clutch pedals, accelerator and H-gate gear-shift.

There are four body designs, as already brought out. These consist of the two touring car types, one for each chassis, and two roadsters. The bodies are designed along the lines of present-day automobile fashion. All door hinges are concealed, as well as the handles. On the 6-55 model provision is made for the carrying of the spare tires in the rear. The metal dash of cow type is also typical of the latest in body design.

The arrangement of the various control devices on the dash is shown in Fig. 5. The muffler cut out is seen at A, while the accelerator, which is of peculiar form, appears at B. Instead of being pressed down to admit more gas to the cylinders, this eccelerator lever is moved in a horizontal plane around its center as an axis in much the same manner as the throttle lever on the steering wheel is moved, the only difference being that when the accelerator arm is released it returns to its original position just as any other type does. The lock ignition switch is shown at C, the sight-feed of the oiling system at D, the speedometer at E, and its pilot lamp at F. The aim has been to make all the dash apparatus as accessible as possible to the driver.

The Knickerbocker speedster, so-called, is worthy of more than passing mention, in that it is a new effort for the Havers company, which believes that there is a demand for a machine of this type, built along attractive and racy lines. The car is shown in Fig. 6. The gasoline and oil tank is carried back of the seat, which has a comfortable angle. Back of the tank is the trunk for supplies of clothing, and the spare tires are mounted in the rear.

The equipment of the 6-55 models consists of Gray & Davis black and nickel lamps, mohair top with patent inside curtains, ventilating windshield, horn (placed under the hood), foot rail, coat rail, extra rim, tire irons, speedometer and gradometer, together with a full complement of tools. On the earlier 6-44 the equipment is standard, although ignition is not in combination with lighting and starting, as already mentioned. This combined electric starting, lighting and ignition feature is optional with the purchaser, however, at an additional cost.

Harking Back a Decade

FROM *The Automobile and Motor Review*, December 27, 1902: The fifth annual automobile salon, which opened December 10 at the Grand Palais in Paris, is by far the most complete exhibition of the motor vehicle ever seen. President Loubet opened the show. There are sixteen sections included in the exhibition, nine of which have some connection with the automobile. As this account was mailed the next day, your correspondent declares that it will be impossible in this issue to give the American reader any comprehensive idea of the show.

W. K. Vanderbilt, Jr., has entered for the Paris-Madrid race. David W. Bishop is also expected to enter.

In the official report of the late A. C. A. run to Boston and return, it is shown that the contesting cars suffered penalizations for 100 stops. Of these twenty-six were caused by faulty ignition; eleven due to mishaps to the cooling systems and ten each the result of tire and valve troubles. Accidents caused five penalized stops. Among the steam cars 75 per cent. of the stops that brought penalties were due to troubles in the water and gasoline systems.

A good formula for determining the horsepower of a gasoline engine is as follows: Square the diameter of the cylinder in inches; multiply by the length of the stroke in inches; multiply by the number of cylinders; multiply by the number of revolutions of the crankshaft per minute and divide by the constant 18,000.

The Panhard cars of the future will be equipped with Krebs carbureters. This carbureter consists of three parts: First, the air inlet, communicating with the mixing chamber; spray nipple connecting with the float chamber; second, a cylinder and piston, the latter actuated by the centrifugal governor and third, an extra air inlet equipped with cylinder and piston. The advantages claimed for this type of mechanically actuated carbureter is that it consumes less gasoline and is far more certain of producing satisfactory explosions.

High Turbine Supplants Flywheel and Muffler

THE High exhaust motor is designed for the purpose of eliminating the muffler, and of utilizing the exhaust gas in mechanical devices which replace the flywheel, but still perform its functions. By so doing more torque and increased power is claimed besides absolutely preventing all exhaust detonation, without increased back pressure in the cylinder. The device, it is said, can be manufactured as cheaply as the flywheel and muffler which it replaces and it can be designed to be applied to any constant rotation heat motor.

The claims of power and torque are based on the impulse reaction turbine principle, and the claim of silence is based on the ability of the device to break up the fluctuations in the exhausting gas besides expanding it, so that the issuing gas will have a constant and low pressure. The action of the motor is as follows:

The exhaust from the cylinders is led through a gracefully-diverging manifold, Fig. 1, to a position in the motor casing where it will impinge in a pocket, Fig. 2, in the periphery of the rotor rim. The initial velocity of the exhausting gas of approximately a mile a minute is greatly increased by divergence of the manifold so that the gas has considerable momentum when it strikes the rotor pocket. This impulse on the rotor is delivered at a time when the torque curve of the exhausting cylinder is negative. The gas is held by the pocket only during a few degrees of the rotor's revolution when a by-pass in the wall of the case is uncovered into which the gas reacts and expands. This by-pass shoots the gas to the preceding pocket—this pocket uncovers a second duct which shoots the gas against fan blade spokes, which after the impulse shot is past, continue to such gas until the next exhaust shot gives them impulse.

The gas, after passing over the fan blade spokes, is further expanded in a chamber under the cover plate and from here the gas discharges through receding diverging nozzles cast in the front face of the rotor rim into an annular exhaust receiver from whence Exit. The starting-crank is fitted in the cover plate—the disengaging spring making it gas-tight when not in use. The flywheel bearing, which is the only point of friction, is protected from hot gas by having the case overhang the hub and the blade spokes keep the hot gas from that point.

Criticisms of Non-Poppet Valves To-Date

(*Continued from page* 1317)

drive as well as in the whole of the motor construction, have induced many designers to use one valve as a gas distributor for a number of cylinders, that is, a valve with a single set of passages alternately serving the different cylinders. Among the representatives of this class are the Itala, Figs. 2 and 3, and the Silent valve, Fig. 9. In both of these cases a single valve is provided for each pair of adjoining cylinders.

It may be proper to mention in this connection the Banner engine, Fig. 10, with all cylinder axes parallel; and also my arrangement, roughly represented in Fig. 11, and intended for V-shaped engines. Many other similar schemes could be evolved. Their merit would be simplification.

There is one group of rotary valves for which very little success can be expected and which deserve much scepticism based even on the scarce experimental data of today. These are the valves openly exposed to much heat either by serving as exhaust gas carriers for a large part of their length, or, still worse, forming a part of the explosion chamber. The valves could be used partly for exhaust gas passages only when they have cooled outside shell, which comes in touch with the bearing surfaces of the valve-inclosing space. If the valve has no cooled shell but the hot gases come in direct contact with the exterior valve walls these will attain high temperatures differing widely from the mean temperature of the water-cooled valve seat. The expansions of the valve and its seat cannot be uniform and proportional with respect to each other, thus resulting in a variation of the valve clearance with the state of the motor action. This criticism is applicable to valves of the type shown in Fig. 12. There may possibly be some justification for this arrangement of outer exhaust passages and inner inlet space if the motor was intended for fuels needing forced evaporation before entering the cylinder, but scarcely otherwise. In any case the design does not look satisfactory from the point of valve functioning, the valve either leaking when cold or sticking when the motor is hot. The valve, Fig. 12, could be quite practical, at least it has more chance to be so if the method of carrying of the gases were reversed, that is, having the inlet gases outside and the exhaust gases passing through the internal passage.

New Stanweld Rims

Made in Seven Types, Four Being Quick Detachable and Demountable—Others Are Detachable Only

Stock Used Is Hot-Rolled Steel Electrically Welded—Rims Made to Stand Side Load of 2 Tons

THE latest type of rim to enter the field comes from Cleveland, O., from the rim plant of the Standard Welding Company, pioneer in rim making. This concern has been engaged in the making of automobile and bicycle rims for some 14 years, hence its product has necessarily reached a high degree of perfection.

During the first few years of its existence the Standard Welding Company occupied a space of about 30,000 square feet and employed in the neighborhood of 100 men. Since that time it has gradually expanded until at the present time the factory has a floor area of about 8 acres and furnishes employment for about 2,000. The plant operates the year round for 24 hours a day, welding, shaping and other rim-making operations being carried on as in the daytime.

The new products have supplanted all other types in the plant and they are known under the trade name of Stanweld. They come in seven types, four of which are quick detachable and demountable, while the other three are detachable only, the demountable feature being omitted.

The demountable types are the most interesting. Figs. 7 and 8 serve to show their construction. Both of these, which are identified as Nos. 40 and 41, are the same with the exception that the former is a universal type, while No. 41 is intended for straight-side tires. Both rings A and B are removable in the case of No. 40, as Fig. 7 indicates. The dotted lines show how a straight-side tire ring may be placed on the base C instead of the clincher rings, if desired, making this type universal. In addition to the two types of demountable shown there is the rim which is designed for use with clincher tires only, in which case the tire supporting ring is a part of the base. It is the same as the straight-side rim, Fig. 8, except that the rings are concave instead of convex, as at RB.

In all three the demounting features are the same, so that we will confine ourselves to an explanation of that shown in Fig. 7. Referring to this figure, it will be noted that the rim consists of four principal parts, the rim base C, the adjusting ring D, the felloe band F and the locking device or clamp L. The adjusting ring D is the most noteworthy feature of the whole design, for its construction removes all excessive strains from the clamp bolts because such pressure can reach them only indirectly. The beveled portions of the adjusting ring D, which are in contact with the mating bevels of the rim base C, tend to force the latter toward the inner side of the wheel. This movement is resisted by the flange F_1 which is an integral part of the inner side of the felloe band F. The bevel construction also has a tendency to force ring D out, but any such movement is checked by the clamp L and also in large part by the friction between the flat surfaces of F and D. Thus it is evident that there is very little pressure exerted upon the clamp.

The design of ring D and the mating bevels of the rim base C prevent any lateral or side motion of the latter because it is held fast by the very wedge nature of the construction. The absence of such side motion is a big factor in tire economy. Another feature of the construction which is evident to the reader is that radial vibration which the rim may undergo in travel can in no way be transmitted to the clamp L, as it can receive only lateral force.

There are six of these clamps L for each wheel. These are of rotary type and operate on bolts N extending through the wheel felloe S, as shown in Figs. 1 and 2. The bolt heads M have the peculiar form shown and they support the felloe band F on the inside of the wheel. These bolt heads M are drilled for the screws T, which prevent the bolts from turning when the clamp nuts are being operated.

The clamp has a universal movement on the driving nut V so that, in loosening the latter by turning to the left with the special socket wrench furnished, the clamp is also turned in this direction and its lip L_1 then clears the ring D, allowing the latter to release its wedging action and permitting the rim to be removed. Tightening on the nut, or turning to the right, swings the clamp into vertical position, engaging the adjusting ring. Thus the clamp is automatically put in locking position or removed from engagement with the rim, depending on which way

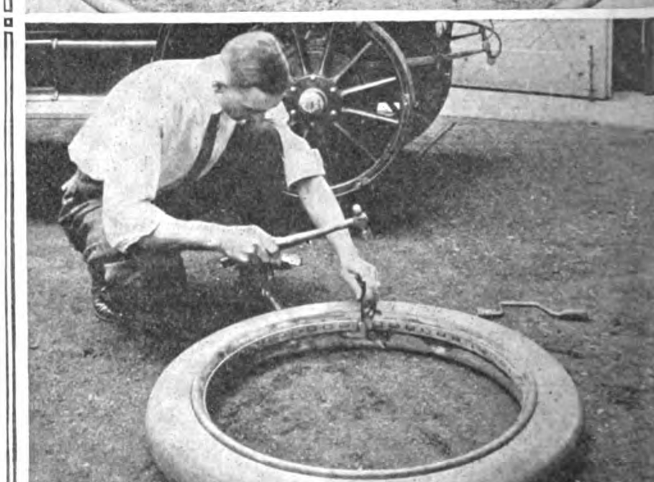

Fig. 1—Wedges removed and rim being lifted from wheel
Fig. 2—Showing construction. Both sections are locked
Fig. 3—Unlocking swinging latch holding locking ring ends

the nut is turned. The clamp and nut are held together by means of the friction spring FS, Fig. 7, which passes around a collar integral with the clamp nut V, and the ends of which fit in a groove in the lower part of the clamp. Unless undue resistance is brought to bear this spring is tight enough to cause the clamp to turn with the nut, but when the former has turned to the side until it meets a projection of the clamp washer W, Fig. 7, the frictional hold of the spring is overcome and the nut turns free of the clamp, tightening or loosening as the case may be. The construction of the clamp may be understood from A, Fig. 7, which shows clearly the spring S_1 and the manner in which it passes around the nut collar or projection C_1. The clamp A_1 is also clearly seen.

Another distinctive feature of these new rims is the method of removing of the side ring for the replacement of a tube or casing. Fig. 9 shows the construction when locked and when

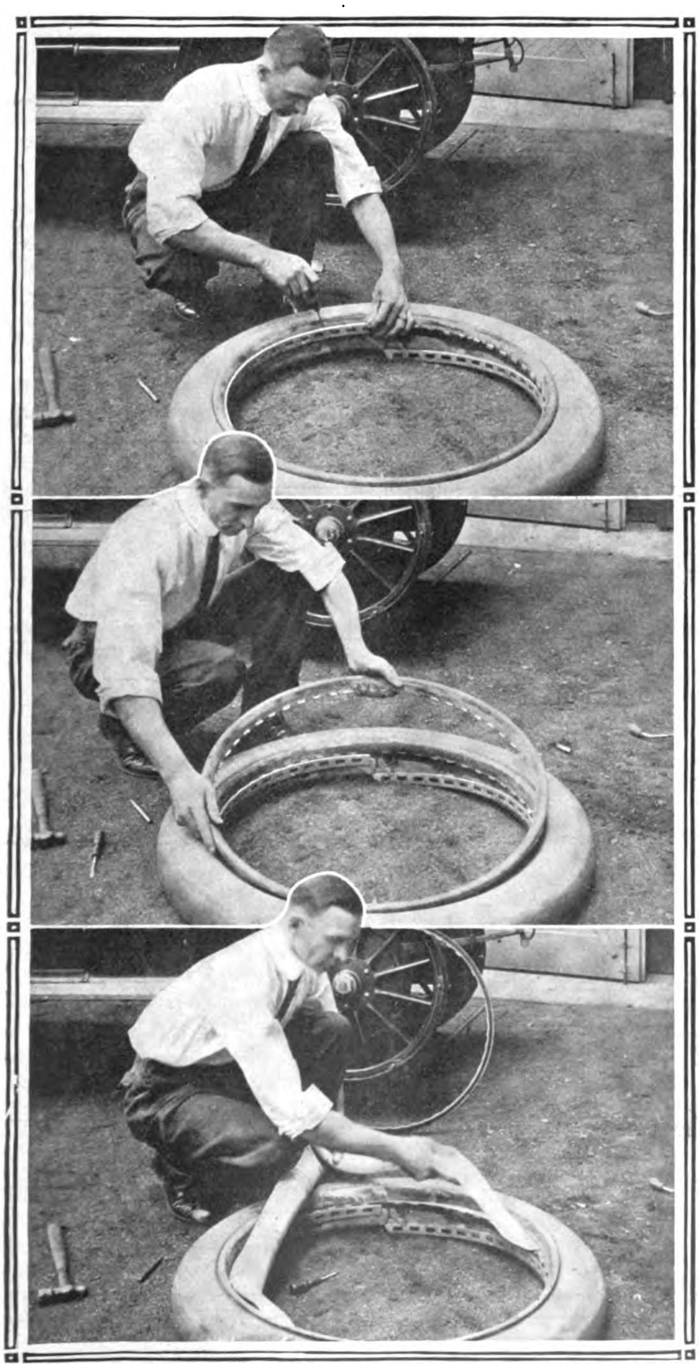

Fig. 4—One locking ring removed. Other being loosened
Fig. 5—Narrow section of the rim base being removed
Fig. 6—Showing the process of removing the inner tube

unlocked. On either end of the split ring B there is a lug Y, which is slotted, and which passes through a hole in the rim base C. These lugs lock by means of a cam O, which is turned by the integral lever X. When in the locked position the cam sides fit into the slots in the lugs, preventing them from being removed. The lever is held locked by means of a latch, consisting of a small button or projection on the end of the lever which fits into a recess or groove in the under side of the rim.

To remove the ring a screw-driver is all that is needed. This is inserted between the rim and the lever, and the ball catch on the end of the latter is pried from its seat in the rim socket. The lever is then turned outward, causing the cam to clear the slots in the lugs, and allowing these to be pried upward through the slots or holes in the rim base. In doing this the screw-driver is placed in the notch P, which is formed in the base of the ring for that purpose.

Figs. 12, 13 and 14 show the sections of the detachable types which are not demountable. These are designated as Nos. 50, 51 and 52, respectively. No. 50 is a universal type, that is, it may be used for either clincher or straight-side tires depending on which type of side rings are used. The other two are designed for either type, but are not interchangeable, the inside ring being a part of the rim base, as shown. With all three the outer ring is split and locks the same way as do the demountable types, by the use of the cam-locking device just described.

Another type of rim is made by this company, which is known as No. 30, and it differs considerably from the other designs already mentioned. This is a circumferentially-split ring, and intended for cars which require a rim of very light weight. The series of photographs of this rim serve to show how this No. 30 is constructed, and at the same time bring out its manner of operation, which is seen to be very simple. The demounting device consists of six clamps or wedges which operate on bolts extending through the felloe and holding the inner ring on the inner side of the wheel.

The detaching of the tire with this type of rim is accomplished through the taking apart of the two halves of the rim, of which the tire bead holding rings are integral parts. The rim is seen to be really two circumferentially-split half rings, each half being provided with lugs which extend inward and which correspond with similar lugs on the other half. Slots in the spring rings, which are of semi-circular form and which are riveted to the wider half of the rim, fit around these pairs of lugs when the two halves of the rim are locked together, thus tightly binding them into a complete rim. The free ends of the slotted spring rings which hold the lugs together are locked by means of a swinging latch which in turn is secured in place by a form of cam arrangement. These parts are pivoted to the wider half of the rim, and therefore there are no loose parts.

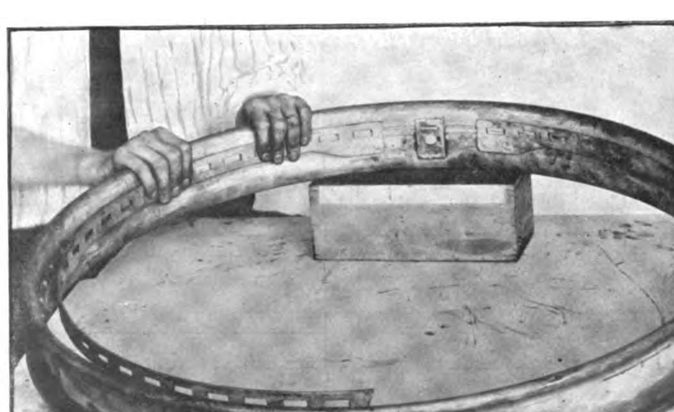

Fig. 11—Locking ring sections of Stanweld No. 30. Slots in rings being fitted over lugs

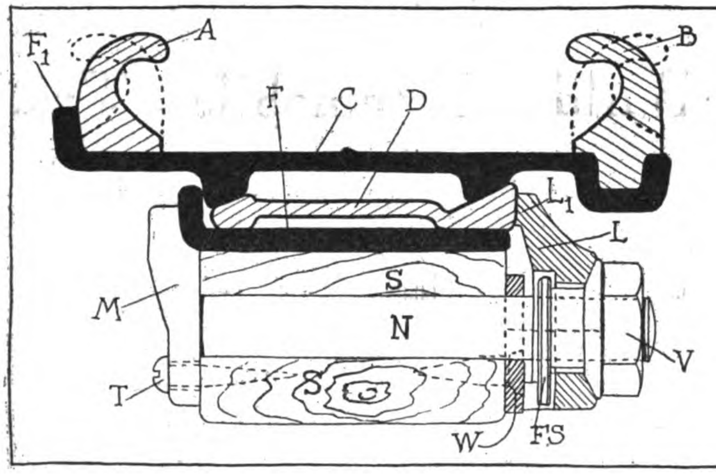

Fig. 7—Stanweld universal quick detachable demountable rim.

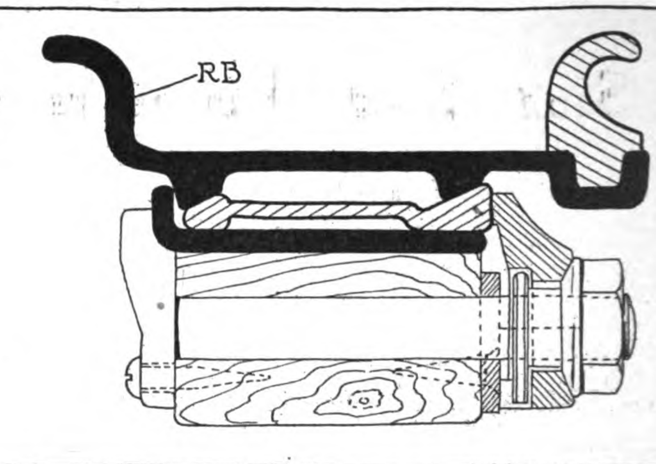

Fig. 8—Quick detachable demountable rim for straight-side tires

The cam-locking device and the means of unlocking it are shown in Figs. 1 to 6, showing steps in the operation of this rim.

As most of our readers are not familiar with rim-making, it may be well to add that all welded portions are so constructed electrically, the stock being hot-rolled, open hearth steel. The composition of this material is as follows:

Carbon	1.2 to 2.0 per cent.
Phosphorus	Not to exceed 0.5 per cent.
Sulphur	Not to exceed 0.5 per cent.
Manganese	0.65 per cent.

The material is also subjected to a number of physical tests. The tempered stock is required to bend down upon itself cold without fracture at the bend. The following physical characteristics are exacted:

Elastic limit	Not less than 50 per cent.
Elongation in 8 inches	Not below 25 per cent.
Reduction in area	Not below 50 per cent.
Tensile strength	Not under 63,000 pounds per square inch.

The majority of the smaller attachments to the rim are drop forgings, only one or two being constructed from malleable iron castings.

The representative of THE AUTOMOBILE, on a recent visit to the factory of the Standard Welding Company, had the various parts of one of the concern's latest types of rims weighed, in order to gain some idea of just how much the rims added to the total weight of the car. A No. 40 rim, size 36 by 4 inches, was used, with results as follows:

Felloe band	7 pounds
Adjusting ring	5 pounds
Rim base	16 pounds
Endless side ring	5.5 pounds
Detachable side ring	6.5 pounds
Six clamping devices	2 pounds
Total	42 pounds

Thus a set of five rims, four in use and one spare, add the small amount of 210 pounds to the car's total weight. It must be said in justice to the other rims of the Standwell make that the one weighed was the heaviest of the company's manufacture, since it involves both the demountable and the universal features, as already explained.

A test of this No. 40 rim was made by the Department of Applied Mechanics and Hydraulics of the Case School of Applied Science at Cleveland recently, with results as follows:

Load applied, pounds	Adjusting ring, lateral deflection, inches	Rim, lateral deflection, inches
000	.330	.025
500	.330	.026
1,000	.330	.025
1,500	.330	.025
2,000	.330	.025
2,500	.330	.025
3,000	.330	.025
3,500	.330	.025
4,000	.330	.025
4,500	.330	.025
5,000	.330	.025
6,000	.331	.025
7,000	.332	.025
8,000	.332	.025
9,000	.332	.025
10,000	.334	.025

This shows that the rim is not disturbed by a side load of 10,000 pounds, while the adjusting ring is bent laterally not to exceed .004 inch under loads of 10,000 pounds, which shows that a properly constructed automobile rim of today is by no means a weak part of the car.

Owing to the care given by the rim makers to their products, tire replacement is no longer the burden which it was in the past, but the new devices must be understood for their simplicity to become apparent.

Sing Sing Prisoners Build Automobile Truck

Can Be Unloaded in 1.5 Minutes—Has a Steel Body with a Capacity of 8 Cubic Yards—Is Very Simple in Construction, Employing a Worm and Gear—First Time Used on Dumping Body

STREET-Cleaning Commissioner Edwards, New York City, has solved the problem of the cartage of that city's refuse. In 1910 the commissioner and the superintendent of industries at Sing Sing prison took up the question of motorizing the department, and for over 2 years the men have been working on a machine which they built by hand and which was recently seen on the streets of New York.

The truck is constructed of steel, has a body with a mean capacity of 5 cubic yards water measure, but when fully loaded carries 8 cubic yards, and is so constructed that the top of the sides is of a reasonable height, permitting easy loading. It has a cover of a new design which is dustproof and which will confine odors during transportation. This cover is easy to operate, is in sections, having a number of doors, only one of which can be opened at one time, and which will not interfere with the loading. The doors operate easily. This cover really does prevent dust being blown about in the loading operation, which is the great nuisance attending the use of open or partly open carts.

Worm-and-Sector Dumping Device

The body of the truck is dumped by a peculiar mechanism, which permits it to be completely and speedily emptied because it raises the body to a perpendicular position. This raising mechanism is composed of a worm-and-sector gear, here used for the first time in connection with a dump cart. This device is not only effective, but it is the safest possible, because it has a safety device locking the body while being raised, so that there can be no injury by the fall of the body, and is so arranged as to stop when in exactly the right position for dumping, be held perpendicular for the dumping and then be lowered.

This makes the operation of dumping completely automatic and independent of the driver, which meets the requirements usually made for such a device of being foolproof. It is a stanch machine, simple in construction and with little danger of getting out of order, even in inexpert hands.

Not only is the motor truck a time saver, but it is expected to net the department about $2,400 per day, which is a substantial item to be considered in department work. The cost of a cart per day is $4.65, and the estimated cost of trucks would be $20, so that there is an apparent saving of approximately $8 per day for each of these vehicles, and when it is remembered that the department operates about 1,800 carts, it can be readily seen that such a conveyance is needed.

The accompanying illustrations show the truck before unloading and after. The splendid adaptability for dock purposes is apparent, and its quick service in unloading in 1.5 minutes renders it a highly important acquisition to that department.

Bodies Big Feature at Paris Salon

(*Continued from page* 1303)

means of which the stud just mentioned, together with the seat, can be moved backwards and forwards, thus giving adjustable depth. The back is also separate and is really a cushion built on a suitable frame, the frame having attached to it a couple of flat-blade springs so curved that they pass under their seat and have their extremities received in notches in the platform. By means of a roller brough up against the back of the blade springs the back can be inclined to any degree, and the seat passing underneath the back, its depth can also be varied within wide limits. By making the upholstery entirely independent of the body, shocks transmitted to this latter are not received by the passengers.

Digest of Leading Foreign Journals

(*Continued from page* 1314)

in this instance the tar had been spread in close proximity to the trees, interfering with watering and nutrition—the same blunder which accounts for any damage done in the Bois de Boulogne.

Replies to circulars sent out in Germany also acquit the coal tar. The officials in charge, such as Inspector Lipps of Rhenish Prussia and Von Steglitz of Schwenke assert that properly done the tarring is harmless. Inspector Engelhardt of Danzig has observed that at most a few plants with especially sensitive epidermes are somewhat injured. The chief engineer at Alexandria, Egypt, has found from extensive experimentation that the vegetation in his country does not suffer at all from the use of ordinary coal tar on the roads, and he gives a detailed account of the tests he has made.—From *Zeitschrift des Mitteleuropaischen Motorwagen Vereins,* Nov. 30.

Painting the Steel Body

Sheet Steel Surface Presents Poor Foothold for Both Oil and Pigment—Has Little Absorption

IN connection with painting the sheet steel automobile body it has been demonstrated that **the steel's capacity for absorption is comparatively small when compared with that of wood.** The same quantity of linseed oil used for a primer to be applied to wood would be altogether excessive for a steel surface primer. It would, in fact, if used upon the metal surface—and in this particular matter we may also include the aluminum surface—result in the formation of a paint skin, tough and leathery on the surface and soft underneath.

It is very plain, therefore, that if the same quantity of thinning medium is to be used in a given amount of metal primer as would be used for the wood primer of like amount such medium should consist of **a minor part of raw linseed oil and a major part of some other medium** and a portion of this thinning medium will naturally consist of turpentine. The remaining portion may be finishing varnish. As a matter of fact, finishing varnish has been used for the purpose; and by some very able workmen has been recommended as one of the most dependable primers for metal. The writer has used it in a clear state, unfortified by pigment, for galvanized iron surfaces—one of the most difficult surfaces to make paint adhere to, by the way—and the results have been invariably satisfactory. **The steel surface to a greater extent than any other offers an inadequate foothold for raw linseed oil** as there are no pores for the oil to penetrate. In many of the ready-to-use steel primers finishing varnish is largely used and with such primers no fault is being found.

In about every way conceivable it has been proved that the fewer coats applied to the steel surface, consistent with the measure of protection required, the greater service and durability secured. The best paint or pigment to put next the steel is one that offers the maximum inhibition of corrosion on the steel. Moisture, acids, gases and even oxygen orginate and promote corrosion. **For continuous corrosion moisture must be present.** When the steel is pickled there is a free acid set loose which not only creates corrosion but serves to promote it.

However, paints for steel surfaces should have other desirable qualities beyond those which give it power for the inhibition of corrosion. Wearing properties, capacity to stand up under the hard and varied service to which the motor car surface is daily exposed, must be in addition to this power of preventing corrosion. Moisture, more than any other agency, develops and accelerates corrosion and **to prevent moisture is therefore all important.** Raw linseed oil, soya bean oil, and similar oils now acclaimed the supreme oils, are not fully capable of excluding moisture wholly. These oils are all too porous; and it is only when varnish is added in positive quantity that the non-porous surface condition is obtained. In connection with the use of varnish for the metal surface, an overdose of the varnish will render the surface glossy, a condition not at all desirable in a coating of material to be further coated upon. Naturally, **this question of porosity depends to no small degree upon the fineness of the pigment.**

In respect to the best pigments for use upon the metal surface there are divers views. The famous Atlantic City steel panel test has recently shown for American Vermilion a rating of 10 as compared to four lead and zinc compounds with a rating of 9. All these panel exposure tests are not absolute in their findings, especially when brought into the carriage and automobile shop. They have their value, however, in determining certain merits possessed by the materials, and to this extent they may prove of real worth to the vehicle painter in his pursuit of the pigments best adapted to his especial needs.

After all has been said and done in connection with steel surface primers and paints we still have as an uppermost theme the preparation of the metal for the reception of the coating.

When possible, sand blast the metal. This, it has been demonstrated past all dispute, is the most economical and the most direct way, and leaves nothing upon the surface, or within the crystals thereof, detrimental to the paint applied. Lacking the apparatus necessary for this work, **there remains one method: hand emerying.** Also, if available, there are rotating grinders and emery wheels. Hand emerying is, to be sure, a crude method as compared to the use of the emery wheel or the rotating grinder, but it is one immediately within the reach of all. **Another method, and one considerably used by manufacturing concerns, is the so-called pickling process.** This is done with either sulphuric or hydrochloric acid, both of which, however, penetrate into the minute intercrystalar crevices of the metal. The sulphuric acid is a non-volatile medium and hydroscopic—that is, it does not dissipate into the air, but does absorb moisture to a large extent—and unless washed from the surface completely it develops corrosion in the metal under the paint, which corrosion continues until ultimately the entire surface is involved and the paint structure finally splotches and shatters beyond any remedy short of complete removal of the pigment. **The only sure way of removing sulphuric acid traces consists in washing with a stream of hot water applied under considerable pressure.**

In comparison to the sulphuric acid, the hydrochloric acid, as a pickling agent has the advantage of readily volatilizing, even at a low temperature, and it does not absorb moisture to the extent that the sulphuric acid does. That is to say, it is not hydroscopic. **Its action if left upon the steel is nevertheless similar to that of sulphuric acid,** and it is therefore necessary in using it to wash it very thoroughly from the metal. In the use of either of the two acids it is a good practice as a final process in the work to use lime water with which to neutralize the acid traces.

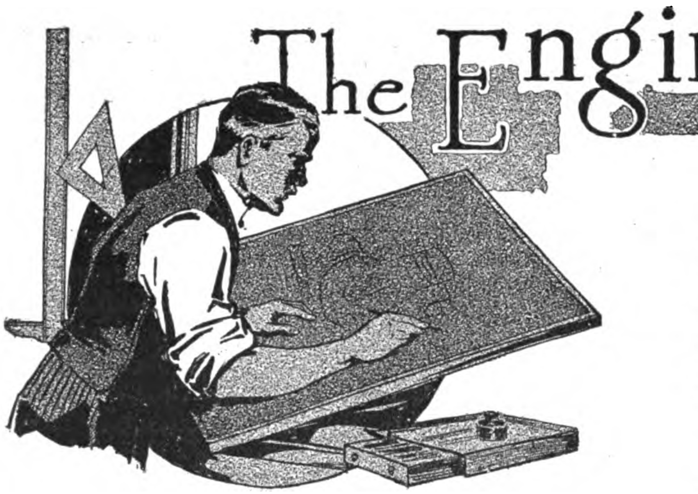
The grinding or machine emerying is a slow proceeding under which the sheets of steel, or the steel surface in whole, are easily bent or buckled.

Hand emerying is a still slower method and it is recommended to the automobile painter only as an emergency practice. The question may arise in the mind of the reader why the elimination of the sulphuric acid traces may not be accomplished by consigning the surface to a baking oven, and in reply it may be stated that **the acid does not volatilize below a temperature of 350 to 450 degrees Fahrenheit,** while the ordinary baking temperature is from 200 to 300 degrees Fahrenheit.

In the earlier days of the steel painting industry it was customary to coat the surface with a sufficient foundation of priming and surfacing pigment to develop under the rubbing process a surface both smooth and level. This rubbing was done with water and artificial pumice stone or rubbing brick. Thus, in rubbing off the high places to the level of the lower ones more or less of the metal was sometimes laid bare and under this exposure to the water moisture attacked the metal with the result that corrosion speedily became an uncontrollable surface disease.

By the present practice, however, all this trouble may be corrected. **Instead of using water in connection with the rubbing brick for leveling down and making the surface smooth, raw linseed oil is substituted as the medium in which to moisten the stone.**

The Engineers' Forum



Four-Speed Gearbox As a Saver of Fuel

H. Ward Leonard Also Says High Engine Speed Necessary with Three-Speed Gearbox Is Hard on Motor

Lighter Transmission Mechanism, Higher Economy and Greater Durability Results of Smaller Motor

THE increasing cost of gasoline is forcing automobile engineers to use gearboxes employing four forward speeds instead of three. There is no question whatever that a saving of gasoline is effected where four speeds are available instead of only three, and this fact has been repeatedly demonstrated, both theoretically and practically, by European and American engineers.

When four speeds are employed it was formerly the universal practice to have the direct drive on the fourth speed but in recent years the most advanced engineers have been gradually learning to appreciate that the employment of a direct drive on the third speed with a geared-up fourth speed gives a most useful result in the case of an average car under ordinary conditions of use.

Many engineers still think that three speeds are practically as good as four speeds, and also think that if four speeds are to be used the direct fourth is as good as, or better than, the direct third, with indirect fourth, but this is often due to a lack of appreciation of four-speed gear-box with the direct third speed.

To consider the questions involved, it is first necessary to consider the characteristics of a modern gasoline engine.

The power curve of a modern four-cylinder gasoline engine of average size rises until it reaches about 1,500 revolutions per minute when it will be producing its maximum power. Then the power curve begins to droop and soon rapidly falls to an insignificant figure.

When a gasoline engine is driven on merely friction load at its maximum possible speed the power which it is able to deliver is practically zero. But at this maximum speed the engine is being subjected to terrific internal strains and the difficulties of lubrication become a most serious matter. The difficulties of lubrication are perhaps most pronounced in the case of the cylinder walls and a great many of the best modern cars are equipped with automatic devices for greatly increasing the flow of the oil at the highest engine speeds.

Evidently the best engineering results could be obtained if the engine were never driven at speeds greater than that needed to produce the maximum power. Suppose the maximum power is produced at 1,500 revolutions per minute. At this speed lubrication is simple and there are no abnormally destructive effects due to the reciprocating parts. Suppose the gear ratio is such that the car can be driven on the direct drive at 36 miles per hour with the engine going at 1,500 revolutions per minute. The direct drive is then available for all customary touring speeds without racing the engine.

But in practically all cases the owner of the car will occasionally drive the car on a level road or slight down grade at the highest possible speed. He may succeed in forcing the engine to go up to 2,100 revolutions per minute, and drive the car at 50 miles per hour. **But in so doing he is likely to do more harm to his motor in a few minutes than would be the case in years of use at speeds not exceeding 1,500 revolutions per minute,** which is the speed we have assumed to represent the maximum power.

If the car operator has a fourth geared-up speed giving him a gear ratio which enables him to utilize his maximum power at 1,500 revolutions per minute, he can readily drive the same car at a much higher speed than 50 miles per hour while running his engine at a speed which makes extraordinary lubrication systems unnecessary, and he also avoids subjecting the engine and car to the destructive effects due to excessive engine speeds. And the engine being well balanced at 1,500 revolutions per minute, the entire car runs more smoothly and holds the road better.

Every engineer will admit that if the car is to be driven at 50 miles per hour it is better to do so by means of an engine running at 1,500 revolutions per minute rather than by the same engine at 2,100 revolutions per minute provided that the direct drive is available in both cases for ordinary grades and speeds.

With the three-speedbox and direct on third speed the tendency is to higher and higher engine power because this single third speed must be able to mount considerable grades and yet drive the car at the highest speed.

The employment of the four-speed gearbox with the third speed direct **tends to more moderate engine power which leads to a lighter weight for all the transmission mechanism, higher economy and greater durability.**

The great importance of preventing the operator from running his engine at excessive speeds is clearly indicated in the fact that the best modern motor trucks have their engines equipped with a governor which prevents the operator from racing his engine at these destructive highest possible engine speeds. In the case of trucks efficiency and durability determine the design far more than has been the case in the design of pleasure cars until recently. But the users of motor cars are rapidly being educated so that efficiency and durability will soon be given more consideration than heretofore, and the stunt hill climber which uses 50 per cent. more gasoline than necessary and lasts but a fraction of the time it should last is rapidly falling out of favor, and will eventually be replaced by the car of maximum efficiency and minimum depreciation of the same maximum speed. It is, therefore not surprising to note the gradual increase of the four-speed gearbox having the third direct, and it seems likely that the maximum speed governor which has proven of such value in the truck field will soon be applied in the pleasure car field, as a simple means of preventing these excessive engine speeds.—H. WARD LEONARD.—Ward Leonard Electric Company.

Increasing Efficiency

THE pendulum is swinging more than ever to production in the American factory. Production is largely responsible for the difference in the success of many companies of to-day. Frequently the best engineering product does not prove the best investment. In a word, it is not the greatest money maker. Production to-day means a thorough knowledge of the art of industrial management as understood and developed during the lost decade. The success of any great factory lies largely in the ability of its executives, and an executive cannot be a competent executive without a complete knowledge of the principles underlying this art. If the executive is not competent the factory fails to obtain its merited position.

One of the basic principles of industrial management consists in the transference of skill from the executive to those under him. If the executive has not this ability of transferring skill he has not a right to the position he holds. He may hold such a position for a time; his company may imagine he is a success in this capacity, but without this ability of transfering skill he will prove a failure when the real test arises. The results of an executive consist in what he is able to get his subordinates to do rather than what he is able to do with his own hand. Ability to obtain results from subordinates presupposes a very general knowledge of the work by the executive. In other words, the executive, to be competent, must be thoroughly familiar with all the methods and practices that the subordinate must use. It is this knowledge that has helped put the executive in his present position.

Not a few of our factory executives are found sadly wanting when weighed in the balance in this respect. So many of them are entirely inadequate, so far as their knowledge of detail is concerned; and many of them are equally inadequate when it comes to the transference of their skill to those under them. They are lacking in a knowledge of the science of psychology, which is a prime requisite with an executive if he is to be successful in transferring his knowledge to those under him.

In the transference of skill from an executive to those under him the threefold aspect of this work must be kept in view, namely, the executive must first make a systematic use of the experience he has previously gained in this work and impart this to his subordinates; second, he must, in a word, be a student of motion study in its various aspects so as to control effort in order that the minimum expenditure of effort will produce the maximum results; and third, he must increase the value of his subordinates by welfare work in which his personality to an extent is imparted to those under him. When he has assumed this attitude towards those beneath him, then and only then may he hope to attain the results that the trend of the times makes it necessary to obtain if his company or factory is to stand in the forefront.

During the last few months there has been pronounced activity in the automobile industry with the aim of creating, or invigorating the efficiency of the various departments in the industry. Sales managers have realized that the efficiency of the dealers throughout the country must be increased; advertising managers have realized that the efficiency of the advertising campaigns in their various sections of the country must be developed; and factory superintendents and production managers have been working overtime to get greater results from the same force of men, working the same number of hours per day and the same number of days per week.

There is to-day in many factories a deplorable lack of knowledge of industrial management. During the past year not a few concerns have been precipitated in legal entanglements and other factories have been discontinued. In nearly every case it has not been a question of poor car design, poor materials, or poor body style, but always a question of conducting the affairs of the company. One company has not been able to produce, and another company has not been able to sell the product. In either case it has been a lack of knowledge of the basic principles of industrial management. There has been much grasping at everything that might ward off the inevitable hour. But these have not been along proper lines.

For 1913 manufacturers must study and operate more than ever along the principles of industrial management. The motor industry as an industry demands it, and those concerns that are going to live and grow must build upon this art. They must use it in engineering, they must use in production, they must use it in advertising and they must use it in selling. The company which had not been operating in conformity with such a system cannot make the transition in a week, a month, or a year. It takes years to get the various subordinates into the habit stage, which is one of the prime essentials of such a system.

Teaching Value of Safety to School Children

American Museum of Safety Starts Educative Campaign in New York Schools to Prevent Accidents in Traffic Such as Those That Were Noted During The Past Year as Result of Carelessness and Recklessness on Streets

DURING the first 11 months of 1912 ninety-three children under the age of 16 years were killed in vehicular traffic accidents in New York City in which automobiles figured. Several of these fatalities were due to unavoidable mishaps; a few to careless driving, but by far the greater number are chargeable to carelessness, recklessness and negligence of the unfortunates themselves. It has been estimated that twelve of the fatal accidents were caused by roller-skating; the game of tag cost seven juvenile lives; careless riding of velocipedes, pushmobiles and bicycles on the streets by children resulted in eleven fatalities, while reckless acts of children, such as covering their heads while playing in the streets, either in games where a blindfold is used or otherwise, have resulted in serious accidents on numerous occasions.

Various solutions of this problem have been suggested in the past, but when they simmered down they took the form of restrictive legislation against the automobile driver rather than anything that would go to the foundation of the matter. Most of the accidents in New York occur when the automobile involved is traveling well within the legal limit and in conformance with the local ordinances, thus demonstrating the worthlessness of the law as a protector of life in many cases each year.

The situation presented is not how to hamper automobile operation more than at present. It is to educate the public to a true valuation of the dangers of traffic. A child learns from its mother than a hot stove will burn its hands if they come in contact with the stove. Consequently little hands are generally burned no more than once, but the child is allowed to gain its experience of traffic dangers by personal observation. As one accident may mean death, the value of experience is not very high.

In order to protect life and limb in street traffic, as well as the wider field presented by the great industries of the country, the American Museum of Safety was incorporated and maintains offices in New York. The museum is now placing its resources at the disposal of the New York public schools in an effort to check the slaughter of children by working at the foundation of the problem by educating the children to the dangers of the streets.

The method to be used is largely founded upon suggestion. Safety talks are conducted in the various schools under sanction of the Board of Education. These talks outline the terrible dangers that attend playing foolish tricks to torment and tease drivers. The favorite game of Never-Touched-Me is frequently fatal. In this game the player tries to see how close he can come to a fatality without actually suffering one. It has no rules and consequently is a nightmare to the drivers of automobiles, as they can never know what to expect from the player.

The game is played in a thousand different ways, one of the most spectacular of which is to lie down flat on the pavement and allow the automobile to pass along without touching the player. Of course, no child ever intends to take such a chance, but it has been done as many automobile drivers will attest.

Roller-skating in the streets is a fruitful source of trouble. The skaters rarely watch corners even when alone and when they are playing in groups the sudden apearance of an automobile is often unnoticed until the car is right among the children.

Pushmobiles on the streets are an unmitigated nuisance, dangerous to the operator and a source of apprehension to the automobilist.

Hitching on behind automobiles and motor trucks invites disaster. The old-fashioned game of tag, baseball in the streets, hockey, shinny and blindman's buff all are dangerous and all have taken toll of life.

The American Museum of Safety has already presented its safety talks to 10,000 New York school children and the work has only been in progress since December 10. It is planned to continue the work until the whole field is covered.

Aside from the addresses that are made the lecturers distribute leaflets and pamphlets to the children calling attention to the dangers of modern traffic in New York. The idea is to couple a real significance with the term safety. It is pointed out that death is the end of things earthly, and that death lurks in the traffic. That the loss of a limb means a handicap that can only be overcome in very unusual instances in these days of competition. That in either event, the best game of tag or hockey, or the finest kind of roller-skating is not sufficiently large as a consideration for lost life or limb. In other words, while all roller-skaters on the streets are not killed by automobiles and all tag-players are not knocked down by automobiles, the percentage is sufficiently large to make plausible the conclusion that the games themselves are not worth the risk.

Due diligence in the operation of automobiles is only a casual factor in the situation. Only a short time ago a case was reported where a boy ran into the side of the rear wheel of an automobile while playing tag, falling forward so that his arm was run over. The car was proceeding at less than 6 miles an hour at the time and in absolute control.

In the newspapers, cases are reported daily where children have darted directly in front of automobiles and horse-drawn vehicles as well, with varying results. On account of the controlling facilities of the automobile the drivers are frequently able to stop short when there is even the shortest period of warning. Of course, where the child dashes around the end of a street car and runs into an automobile accident is certain.

The conclusion is that where an unfortunate is run over by an automobile the speed of the automobile is immaterial. The main question is to avoid running over the child.

Wanted!—A Car and a Truck

The American Museum of Safety, an organization committed to the preservation of life and limb, with offices at 29 West Thirty-ninth street, New York, initiated a series of Safety Talks December 10, sanctioned by the New York Board of Education, the lectures being delivered to school children. The museum wishes to continue the work and for the purpose requires a four-passenger automobile and a 1,000-pound delivery wagon from now until the end of the school year. The organization requests the loan of such vehicles from the automobile industry as a measure of co-operation in its undertaking. The intent of the work is to educate the children to the dangers of traffic. The museum promises due credit to the lenders of the cars.

New Bodies at Salon Prime Show Feature

Several Unique Designs To Be On Display When Importers Open Astor Doors to Motoring Public

Two-Passenger Landaulet and Four-Seated Limousine in Luxurious Styles Will Attract Attention

CHANGED body styles will be the most palpable difference noted by visitors to the annual automobile Salon conducted in the Grand Ball Room of the Astor, which opens January 2.

At least two entirely new types of bodies will be introduced by the Salon. These are a four-seated limousine of the enclosed drive type, which is becoming very popular abroad, and a two-passenger landaulet, which is readily converted into a runabout by folding down the sides and top. The former is entirely enclosed and there is no division between the front and rear seats. Many of these bodies are fitted with four arm chairs for seats. Some of the new two-passenger landaulets have a third seat for the chauffeur which, however, is not enclosable. This third seat is on the same level as the front seat, so that the chauffeur does not sit above the passengers and driver, as in the old types of three-seated runabouts.

European body fashions for the coming year decree the six-seated car for limousines, landaulets and touring models. By making the rear seat no wider than the others this makes an absolutely straight line body possible, and the tendency toward straight lines has been more pronounced each year. This has another advantage in the case of limousines and landaulets, as the side windows can be dropped all the way down, because the body is entirely inside the rear wheels. With the old style body the windows could only be dropped half way. The six-passenger body of this type is another step toward popularizing the enclosed car for touring purposes by eliminating the bulging back of the three-passenger-on-the-rear-seat type of body this goes a long way toward improving the appearance of limousines and landaulets.

Another new tendency which the Salon will disclose is that of building enclosed bodies very low. This is not accomplished by mounting the bodies lower, for this would be hardly possible, but by providing considerably less head room. It is said that this has resulted in small hats for ladies which are the new fashion, although it is quite possible that the body designers have taken advantage of the new fashion in ladies hats to design a body far more graceful than the old type, with its ample head room. The flat roof for enclosed bodies has given way to the curved roof, so that its lines conform in harmony with the general design.

The interior decorations of the limousines to be exhibited at the Salon will prove a revelation to the average motorist. The upholstery, furnishings and inlaid woodwork of some of these limousines represent an expenditure of several thousand dollars.

Rival Show Announced for Quakers

PHILADELPHIA, PA., Dec. 21—With the question of where it is to be held definitely decided, the show committee of the Philadelphia Trade Association is actively at work completing arrangements for allotting space and other preliminary details incidental to the opening of the twelfth annual automobile show January 18 at the mammoth garage of the Automobile Club of Philadelphia. Space will be drawn for next Thursday.

With 90,000 square feet of floor space at the disposal of the committee this year in one building, as against 60,000 in two buildings last year, there will be no need to curtail allotments nor limit the number of exhibits, as formerly. Many companies that would otherwise have exhibited last year were forced to conduct private displays in their various buildings, owing to the fact that adequate display room could not be obtained in either of the two armory buildings where the show was held. Naturally, they will be in the fold this year, and as the Automobile Trade Association comprises an active ownership of 60 dealers, representing 90 different makes of cars, in addition to an associate membership of 20 accessories dealers, all or most of whom will exhibit, the show will be the largest and most representative of the industry ever held here.

The exhibition committee of the Philadelphia Automobile Trade Association consists of Louis C. Block, Ford Motor Company, chairman; W. P. Herbert, Lozier; H. M. Coale, Autocar; F. W. Eveland, Stevens-Duryea; A. E. Hughes, Pierce-Arrow, and H. Warren Terry, assisting secretary.

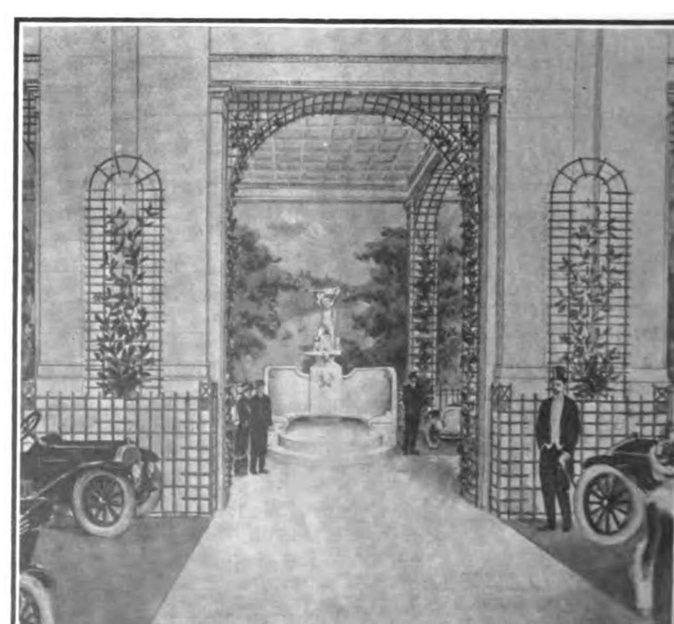
Quite a flurry has been stirred in local automobile circles by an announcement that J. H. Beck, a former secretary of the Philadelphia Automobile Trade Association, will conduct an independent show in the First Regiment Armory in opposition to the big show. This show will also open on January 18, under the auspices of the Philadelphia Automobile Board of Trade, Ltd., a recently organized body, but in no way connected with the Philadelphia Automobile Trade Association.

Hoosiers to Come East in Style

INDIANAPOLIS, Dec. 21.—Indiana automobile manufacturers are going in a body to the New York show and have arranged for a special train over the Pennsylvania Lines, which duplicates the equipment of the Pennsylvania Limited and other famous trains. Nine steel cars will carry them from the Hoosier Capitol.

The train will leave Indianapolis Thursday, January 9, 2 days before the show opens, and will reach New York City at 4:15 p. m. Friday afternoon. This schedule was arranged so that the manufacturers and their guests can make a feature of the dinner on Thursday evening and ride through the mountains and the beautiful main line suburbs of eastern Pennsylvania by daylight.

Soon after the train was announced the committee, composed of W. D. Edenburn and F. E. Wilson, of the Henderson Motor Car Company, and W. McK. White, of the Marion Motor Car Company, had received 112 reservations for space from people all over the Hoosier state.



Roman exedra to be seen at Grand Central Palace

Show Decoration Will Strike Harmonic Note

New York Automobile Display to Be Housed Amid Settings That Will Bring Out Beauties of Cars

French Grand Prix To Be Run Over 19-Mile Course North of Paris Near Amiens Having Triangular Shape

A GOOD idea of what the interior of Madison Square Garden and Grand Central Palace will look like when they have been converted to the purposes of the Thirteenth National Automobile Show, which is to be held in both buildings for 2 weeks, beginning January 11, has finally been made clear by the issuance of some colored photographs which are now being displayed in store windows in large cities throughout the country. A number of decorative features are entirely new and different from any ever before seen at an automobile show.

The general effect in both buildings is more imposing and impressive than in previous years, and there is very little theatrical or artificial treatment in the decorative schemes. The past 6 months the show committee, which consists of Col. George Pope, chairman; Alfred Reeves, and Merle L. Downs, secretary, have been putting forth strong efforts in their work of preparing an adequate setting not only for the cars, but for the accessories, and the schemes that have been hit upon are unusual. A Crystal Palace is what the show committee terms the decorative effect of the Garden, while the Grand Central Palace will be known as The Palace of Versailles. The treatment of the Grand Central Palace will be along the lines of the old palace of Louis XIV., with fountains, Corinthian pillars, vistas, etc.

The exhibition spaces on the main floor of both the Palace and Garden will be carpeted with a specially woven fabric of light green, to lend something toward the effect of the cars being on the turf. More than 12,000 square yards of carpeting will be used.

Entering the arena at the Garden exhibition the visitors will be confronted by a Roman seat and fountain. The fountain is opposite the center of the seat, which is of a low abutment of gray stone and has a trough-like basin containing gold fish and natural pond lilies, from which varied colored lights will radiate.

In the Garden a wide balustrade will extend along the outer edge of the elevated platform, while the walls at the back will be covered with an imported cartridge paper of golden hue. In the general view there will be three balconies in the rear and in the front of the Garden and but one on either side.

French Race On 19-Mile Course

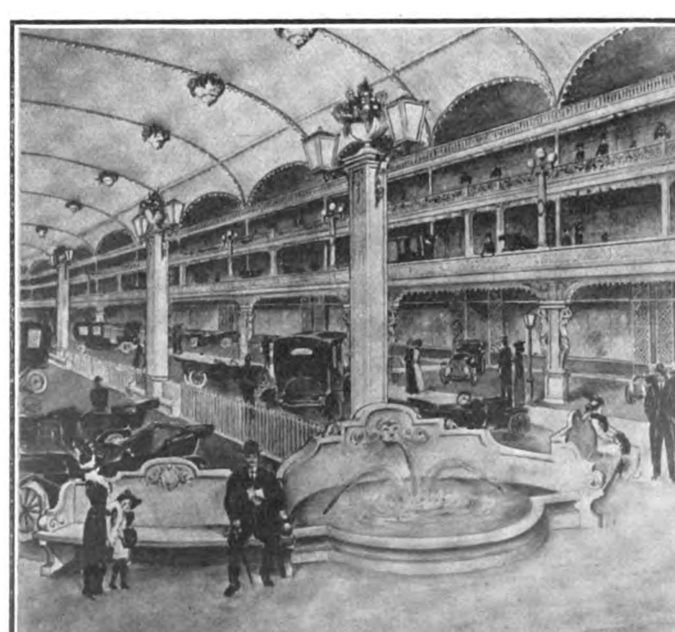
PARIS, Dec. 14—Next year's French Grand Prix race will be run on a 19-mile course, 2 miles to the east of the town of Amiens and 80 miles north of Paris. An official announcement regarding this course will be made next week, but from reliable inside information it is possible to definitely announce that the Amiens course will meet with the entire approval of the racing board of the French club.

Amiens, a flourishing town of more than 90,000 inhabitants, a large proportion of which are interested in the cloth and woolen trade, is on the main railroad line from Paris to Calais, with a railroad station on the main line within a couple of hundred yards of the point where the grandstands will be erected. It is within 80 minutes of Paris by rail, 3½ hours of London, and within easy reach of the Belgian frontier. The town can provide all the accommodation necessary for a big crowd of spectators.

Roughly, the course is triangular in shape, the first leg being a dead straight line 8 miles in length, of an undulating nature and with only one small village on it. This is an ideal speedway, being one on which the cars can be run with wide open throttle from beginning to end. A sharp turn to the right takes the cars on the second leg of the course, nearly 3 miles in length, all of it being straight and level with the exception of the last few hundred yards, which are on a slight downgrade into the village of Moreuil. The third leg measures a little more than 8 miles of a very wide and slightly winding national highway, which twice passes under the main railroad line from Paris to Calais. There are rather difficult S turns under the bridges. During the last half mile the road is parallel with the first leg of the course, the distance between them being so slight that the whole of the land between the two roads has been secured by the racing board and will be used for grandstands and pits. Spectators within this space will therefore see the cars approaching on the national highway, watch them go round the bend, and see them disappear on the fastest portion of the course. It is proposed, instead of taking the cars right down to the fork, to build a special cross-country road uniting the two parallel portions of the course. This will make it possible to provide an easier bend and one which, on being banked, can be taken at speed, thus adding to the spectacular nature of the race. Grandstands will doubtless be erected both inside and outside the bend.

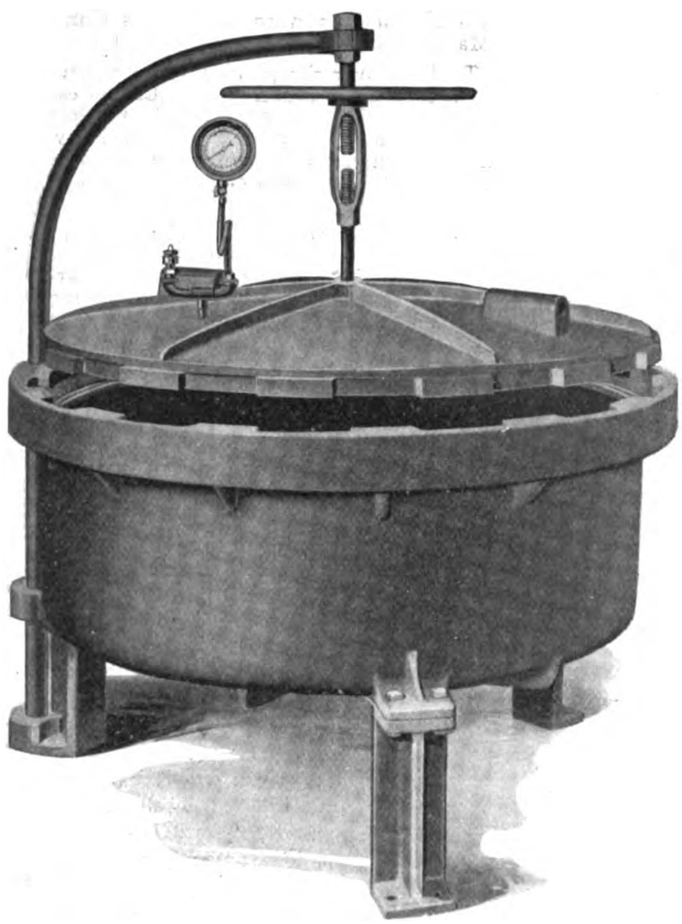
At the present time there are 16 cars for the French Grand Prix race. These are three Sunbeam, three Peugeot, two Delage, one Mathis, three Itala, one Opel and three Schneiders, the nations represented being England, France, Germany and Italy. Final entries close at the end of the year, by which time it is expected that there will be 35 to 40 cars on the list. It is understood that Mercedes will enter a full team, and it is most probable that Fiat and Benz will come in at the last moment. Other firms having the matter under consideration are Motobloc, Piccard-Pictet, Alcyon, Lorraine-Dietrich and Mors. It is quite possible that most of these firms will wait until the last possible moment before putting in their entries, for there is an intention on the part of some of them to bluff rivals out. It is practically certain that the French Grand Prix will be held during the last week of June or the first few days of July.

The 3-liter race, originally fixed for Sunday, June 29, will be postponed until the middle of September in order to give manufacturers an opportunity of taking part in both races and to avoid clashing.



Decorative scheme to be used at Madison Square Garden

Factory Miscellany



Quick opening tire kettle made by the Williams Foundry & Machine Company, Akron, O., for use in the steam curing process. It has the good feature of having no nuts or bolts to tighten when the cover is in place

AFTER the tires are wrapped they are handled in what looks like a prodigious soup kettle. This kettle is for the steam process and therefore must be capable of resisting the pressure of the steam used in the curing of the tire. The kettle shown above is not the largest size made, but is the type used in all but the largest plants. It measures 43.5 inches inside diameter and has a capacity of four tires which are all handled at the same time. The tires which can be taken care of are anything from a 42-inch size down. The curing space is 16 inches in depth above the grating in the bottom of the kettle. The shipping weight of the kettle is 2,100 pounds. It is made of open hearth steel and is tested with 200 pounds hydraulic and 75 pounds steam pressure. It can be opened and closed rapidly by turning the wheel which manipulates a differential screw and nut, lifting the cover. A boltless head is used, not one nut having to be tightened when the cover is put in place. When the tire is cured the steam inlet valve is shut off and the steam in the kettle blown out. The crane lifting the lid can be swung to one side out of the way.

SWINEHART's **New Buildings**—New buildings have doubled the capacity of the Swinehart Tire and Rubber Company, Akron, O. The mill room has been enlarged and the tire building department has had its capacity doubled. A one-story addition, 100 feet by 20 feet, has been built for a chemical laboratory. The plant occupies a three-acre plot and comprises six buildings, the main ones being of three and four stories.

Mayer Building—The Mayer Carbureter Company, Buffalo, N. Y., contemplates erection of a Detroit, Mich., factory.

Tire Plant in Oklahoma—A plant for the manufacture of leather tires for automobiles is to be established at Oklahoma City, Okla., by Don O. Nation.

Sandusky Plant Enlarges—The Sandusky Automobile Parts Company, Sandusky, O., maker of automobile trucks and accessories, is planning the enlargement of its plant.

Corcoran Brothers Build—The Corcoran Brothers Company, Cincinnati, O., manufacturers of automobile and carriage lamps, will soon begin work on a four-story factory addition.

Plans for Addition—The National Motor Vehicle Company, Indianapolis, Ind., has submitted plans for an addition to its factory. The addition will be a three-story brick structure 83 feet by 97 feet.

Parish Starts Work—Another large company has started work in Detroit, Mich., the Parish Manufacturing Company, which has already made shipments. The company will employ over 1,000 men.

Rushing Truck Factory Work—The foundation for the new motor truck factory to manufacture the Traves machine in Ravenna, O., is practically completed, and all endeavors are being directed at present toward completing the plant.

Adds Four-Story Addition—D. Israel, New York City, general metal worker, will build a four-story addition. One floor will be used for manufacturing oil tanks, copper and tin measures and funnels, and the remaining floors for show room.

Buffalo Plant Moves—The Buffalo Top & Trimming Company, Buffalo, N. Y., manufacturer of automobile bodies, tops and accessories, will remove its plant from 108 The Terrace to 121-234 West Chippewa street, where it is fitting up a new factory.

Baker to Expand Plant—Building plans and operations are under way at the Baker Motor Vehicle Company, Cleveland, O., which will increase the size of the factory by about 30 per cent. Most of the new buildings will be occupied by the truck department.

Garford Asks for Bids—The Garford Company, Elyria, O., has asked for bids on the erection of an addition to the automobile plant. One building will be 57 feet by 280 feet, structural steel, saw-tooth roof and the stock room and shop offices will be 45 feet by 45 feet, four stories.

Perfecto Radiator Moves—The Perfecto Radiator Company, Chicago, Ill., manufacturing automobile radiators and specialties, has moved to Racine, Wis., and is occupying a moderate sized plant. Twenty workmen are employed at present, and this number will be increased as more room is obtained.

Rutenber Purchases Factory—The Rutenber Motor Company, of Marion and Logansport, Ind., has purchased a factory at Chatham, Ont., in which to manufacture motors for the Canadian trade. W. Bowen, of the Bowen Manufacturing Company, of Auburn, N. Y., has been placed in charge of the Canadian plant.

Goodyear Doubles Capacity—About March 1, the Goodyear Tire & Rubber Company, Akron, O., will have a capacity of 8,000 tires a day. This will be made possible by three new buildings which have been acquired and are being fitted up for use. With these the capacity of the plant will be just double what it was a year ago.

Michigan Buggy Adding—The Michigan Buggy Company, Kalamazoo, Mich., is erecting an addition, 50 feet by 180 feet, three stories, to its plant, which will be devoted exclusively to its automobile manufacturing department, and its buggy factory will be extended into the building made vacant by the removal of the automobile department.

Brazil May Get Plant—The Brazil, Ind., Factory Promoting club has received a proposition from a large automobile plant which is seeking a new location. The managers of the plant say the company has $80,000 invested in the business at its present location and that if local men will guarantee $75,000 additional capital that it will remove there.

Budd Company Building—The E. G. Budd Manufacturing Company, Philadelphia, Pa., is having plans prepared for a three-story factory building, 75 feet by 500 feet, to be erected at Tioga and C streets. The Budd company manufactures steel automobile bodies and general pressed steel work for the construction of which the new building will be used.

Shows, Conventions, Etc.

Jan. 2-10..........New York City, Importers' Salon, Hotel Astor, Importers' Automobile Alliance.
Jan. 4-11..........Cleveland, O., Annual Automobile Show.
Jan. 4-11..........Montreal, Que., Montreal Motor Show, Drill Hall and 65th Regiment Armory.
Jan. 11-18.........Milwaukee, Wis., Annual Show, Auditorium, Milwaukee Automobile Dealers'. Association.
Jan. 11-25.........New York City, Thirteenth Annual Show, Madison Square Garden and Grand Central Palace, Automobile Board of Trade.
Jan. 18-25.........Philadelphia, Pa., Annual Automobile Show.
Jan. 21-26.........Toledo, O., Annual Show, Exposition Building, Toledo Automobile Shows Company.
Jan. 25-Feb. 1.....Montreal, Que., Montreal Automobile and Truck Show, R. M. Jaffray, Manager.
Jan. 25-Feb. 1......Providence, R. I., Annual Show, State Armory, Rhode Island Automobile Dealers' Association, Inc.
Jan. 27-Feb. 1.....Philadelphia, Pa., Truck Show.
Jan. 27-Feb. 1.....Buffalo, N. Y., Annual Automobile Show.
Jan. 27-Feb. 1.....Detroit, Mich., Annual Automobile Show.
Jan. 27-Feb. 1..... Rochester, N. Y., Annual Show, Exposition Park, Dealers' Association.
Jan. 27-Feb. 1.....Scranton, Pa., Annual Automobile Show, Hugh B. Andrews.
Jan. 27-Feb. 13....Troy, N. Y., Annual Show, State Armory, Troy Automobile Club.

White Plant Expanding—The White Company, Cleveland, O., will add to its factory space on February 1 a one-story sawtooth building, 160 feet by 240 feet, and will be completed at the north end of the plant. It will be used for chassis testing and body fitting and allow for just that much manufacturing expansion in other departments. A high iron fence now surrounds the factory buildings.

Detroit Workers Strike—Because members of the Carriage, Wagon & Automobile Workers' Union desire a shop committee, and the employers, professing to see in this demand a move to establish the closed shop and have refused the men's request, about 1,000 union men have gone on strike in Detroit, Mich. Five plants of the American Auto Trimmings Company and the Briggs Manufacturing Company are affected.

Gilbert in Detroit—To look over the plans for the 14 factory buildings to be added to the Morgan & Wright tire establishment, Detroit, Mich., J. M. Gilbert, general manager of the United States Tire Company, was in Detroit recently. When the additions are completed Detroit will have the largest tire plant in the world. The plant will employ more than 5,000 men and will bring 3,000 additional workers to the city.

Michelin in Wisconsin—The Michelin Tire Company of New Jersey, is the latest tire company to establish a direct factory branch in Wisconsin. The corporation has filed articles and a statement to do business in Wisconsin, giving its capital stock as $3,000,000 and the Wisconsin interest at $25,000. The location of the new branch, which will be in Milwaukee, has not been announced, but definite arrangements will be completed by January 1, the date of the opening.

Mt. Clemens Factory—Three parties, representing an automobile concern, appeared recently before the industrial committee of the Business Men's Association, Mt. Clemens, Mich., and submitted a proposition to locate automobile shops in that city. The representations made seem to be very favorable and the committee is investigating the proposition and the men behind it. The committee will meet again to consider the matter further.

Employees Share Stock Dividend—Notice has been given to the shareholders of the Baker Motor Vehicle Company, Cleveland, O., of a stock dividend of $200,000, of which half will go to the shareholders and half to employees. This is said to be the first case on record where shareholders and employees have been treated with absolute equality in the distribution of a stock dividend. At last reports, the company had an authorized capitalization of $1,000,000, of which $500,000 was outstanding.

Piggins Wants to Move—The Piggins Motor Truck Company of Racine, Wis., manufacturing Piggins commercial vehicles and for many years engaged in the manufacture of motors for pleasure and commercial cars and parts, is considering several good propositions from commercial clubs and business men's organizations throughout the central west to move from Racine. Unless local capital makes inducements, it is believed likely that the Piggins company will entertain invitations from other cities. Nothing definite will be done before the first of the new year, however.

Stockroom of the Standard Welding Company, Cleveland, O., showing the method of storing the rims in stock

Farewell dinner given to Alfred Reeves by the sales organization of the United States Motor Company at Paul Rector's, New York City

CHALMERS Celebrates Ginger Night—Gathering together salesmen, traveling men, district managers and officers in 300 cities throughout the United States, the Chalmers Motor Company, Detroit, Mich., celebrated Ginger Night. At 7:30 o'clock or earlier in all these places simultaneous meetings of the Chalmers dealers and their organizations were held. At the same time a banquet and meeting of heads of departments and other officials of the factory organization was held in Detroit. Throughout the evening the central meeting in Detroit was in telegraphic touch with the other Ginger meetings throughout the country.

Grant Manager Grinnell—S. J. Grant has been appointed Detroit, Mich., branch manager for the Grinnell Electric Car Company.

Classifies Careless Drivers—A Chicago, Ill., judge has classified careless drivers of automobiles and motorcycles as users of deadly weapons.

Jordan Hoffecker Manager—Walter I. Jordan has become Detroit, Mich., manager for the Hoffecker Speedometer Company, Boston, Mass.

McDuffee Western Sales Manager—J. H. McDuffee has been appointed western sales manager by the F. B. Stearns Company, Cleveland, O.

Racine Company's Office—The Racine Brass & Iron Company, of Racine, Wis., has broken ground for a new office building and is making improvements in its works.

Schacht in Baltimore—The Schacht Motor Car Company, Cincinnati, O., will open a factory branch on January 1 in Baltimore, Md., which will be in charge of I. R. Smith.

Haybell Resigns—E. A. Haybell, who has been traveling out of the Washington, D. C., branch for the Studebaker Corporation, South Bend, Ind., has resigned his position.

Ready Resigns—W. J. Ready, superintendent of the Lozier Motor Company, Detroit, Mich., has resigned to become manager of the Star Motor Company of Ann Arbor, Mich.

Trucks Distribute Mail—Motor trucks are to be employed this year by the Minneapolis, Minn., post office to distribute extra Christmas package mail instead of horses and wagons.

Schacht Opens Factory Branch—The Schacht Motor Car Company, Cincinnati, O., recently opened a factory branch at 1700 Broadway, New York City, with a service station at 536 West 49th street.

Kemmerer's New Quarters—The E. A. Kemmerer Automobile Company, of Janesville, Wis., has just taken occupancy of its new garage building, erected at a cost of $35,000 and covering nearly a half block at 206-208-212 East Milwaukee street. The building affords 37,500 square feet of space and 300 cars may be stored in it. It is one of the largest garages in Wisconsin.

Richmond Automobile Doings—The Chesterfield Motor Car Company, Richmond, Va., is in new quarters on West Broad street, while the home of the Foster Motor Car Company has been remodeled.

Building for N. Y. Trade—A twelve-story fireproof building for the automobile trade will soon be completed on West Fifty-fourth street at a cost of about $400,000 and will occupy a space of 57 feet by 100.5 feet.

Philadelphia Firm Moves—The Baker-Bell Motor Company, Philadelphia, Pa., distributor of the Baker-Bell commerce delivery truck, will on January 1 take possession of its new quarters at 665 North Broad street.

Kline Car for Police—The Kline Motor Car Corporation, Richmond, Va., recently delivered to the police department of that city a model 4-40 touring car, which will be used to bring to justice joy riders and speed violators.

Crum Oshkosh President—Dr. J. A. Crum was re-elected president of the Oshkosh Automobile Dealers' Association of Oshkosh, Wis., at the annual meeting recently; F. S. Hoaglin was elected vice-president; A. H. Thom, secretary, and W. F. Scoular treasurer.

Condemn Indiana Road System—The present Indiana road building and road maintenance system was condemned and a radically new system proposed, at the meeting of the Indiana Better Roads convention held at the German House in Indianapolis, Ind., recently.

Clubs Form Alliance—The Antigo, Wis., Automobile Club and the Commercial Club of Antigo have formed an alliance to boost the good roads movement and to raise funds for improvement of highways until the county government can make permanent improvements with state aid.

Ellsworth Completes Garage—The Ellsworth Auto & Repair Company, of Ellsworth, Wis., has completed the construction of its new garage building, but will continue its old garage until next spring, using the new building for dead storage. The equipment will not be added until spring.

Milwaukee Factory Branch Established—The report that the United States Tire Company would on January 1 establish a direct factory branch at Milwaukee, Wis., to supersede the state agency held by the Goodyear Rubber Company, 382-386 East Water street, Milwaukee, has been confirmed. On January 1 the U. S. Company will establish a branch at 454-456 Milwaukee street.

Ryan Manager—W. A. Ryan has been appointed manager of the Ford Motor Company's Detroit, Mich., retail store.

Doyle Resigns—Thomas Doyle has resigned as manager of the Detroit, Mich., branch of the Ford Motor Company.

Chattanooga's Mail Car—An automobile mail wagon has been assured the Chattanooga, Tenn., post office by the department in Washington.

Open Baltimore Quarters—Quarters have been opened in Baltimore, Md., at 308 North Holliday street by the Rhollo Tirefiller Company, which is in charge of C. B. Berry and W. N. Glass.

Armstrong Resigns—Charles A. Armstrong, assistant salesmanager of the Mitchell-Lewis Motor Car Company, Racine, Wis., has resigned effective January 1. A successor has not yet been chosen.

Storing Cars for Spring—The A. A. Atwood Automobile Agency, Toledo, O., is storing over a hundred Overland cars in the warehouse of the D. & C. Steamship Company, at the foot of Madison avenue for spring delivery.

Taylor with Rutenber—Ceil Taylor, formerly engineer for the Chalmers, Hudson and Studebaker companies, is now consulting engineer for the Rutenber Motor company with factories at Logansport and Marion, Ind., and in Canada.

Franklin's Conference—A conference of the Franklin automobile dealers in New York State was held on December 20 at the Franklin factory, Syracuse, N. Y., with D. F. Garber, New York State district sales manager, presiding.

Urban Sales Manager—To succeed F. E. Moskovics, whose resignation takes effect March 1, 1913, Fred J. Urban, special representative of the Remy Electric company in Chicago, Ill., and Detroit, Mich., will become general sales manager.

Denver Club Active—Building a country home at some especially attractive suburban location and improving many miles of Colorado roads are among the activities contemplated by the Denver Motor Club, Denver Colo., for the coming year.

Flegel's Gauge—Harrison D. Flegel, of Racine, Wis., is about to market a new type of gauge for measuring the depth of liquids in tanks. Mr. Flegel has been granted letters patent on the device and is establishing a workshop for its manufacture.

Booths of the Cadillac and R. C. H. Corporation at the Paris Show

Theft a Penitentiary Offense—A victory in the Ohio fight to make the theft of an automobile a penitentiary offense was won December 20 when three indictments, charging grand larceny, were returned against a trio of young men for driving away the car of Mason B. McLaughlin, sales manager for the White Company, Cleveland.

Lewis Honored—Captain William Mitchell Lewis, president of the Mitchell-Lewis Motor Company, Racine, Wis., was made the recipient of the highest honor in the gift of the Milwaukee Press Club at the annual Festival of the Sacred Cat recently, by being dubbed the fourth knight of Bohemia, a degree of recognition of friendship.

Studebaker and Flanders show space at the Paris Show

Physician Loses Wager.—A physician arrested for driving his automobile at more than 40 miles an hour offered in Minneapolis, Minn., to pay an automobile city detective $100 if he could make the car go that fast. The detective won, refused the money and the physician turned it over to a charity. The fine was $20.

Mowe Resigns—J. H. Mowe, manager of the Detroit, Mich., branch of the Firestone Tire and Rubber Company, has tendered his resignation, to take effect January 1. While Mr. Mowe has other plans for the future he will make no announcement of them at the present time. Mr. Mowe will be succeeded by Howard A. Coffin.

Electrics for Pastors—Two churches in Minneapolis, Minn., have adopted the electric car to assist the pastor in making parish calls. The Church of the Redeemer bought a Columbus electric as part of the equipment of the church. The women of Westminster Church presented a Rauch & Lang car to the pastor for his own use.

Princeton's Bus Service—Motor bus service has been installed at Princeton, Ind., by the Stevens Automobile Company of that city. Princeton is one of the most prosperous communities in southern Indiana, but has never had street car service. The busses are making trips over regular routes, each bus passing the public square. The fare is $ .05 to any part of the city.

New Minneapolis Rule—The fire department chief, Minneapolis, Minn., has ordered large red lights placed on automobile fire auxiliary wagons to insure clearing of the street when a run is made. One big light will be placed in front of the machine, one at the rear and one on either side. By a system of signals the apparatus will indicate to the traffic policemen where a turn will be made.

Report Shows Profit—The report of the St. Paul, Minn., Automobile Club's new White Bear Lake club house for the season showed a profit in its first year. Previous years from the club on Lake St. Croix there was a shortage. At the annual meeting in January provision is expected to buy the land on which the lease expires. The property is 32 acres with 9 cottages. The club will erect a new house.

Automobile Replaces Stage—An old stage coach that ran for more than 30 years on the New Albany and Vincinnes pike between New Albany and Hardinsburg, Ind., has been displaced by a motor bus operated by Rhodes Brothers of New Albany. The new bus makes one round trip a day between the two points and thus far has had a profitable business in carrying passengers, baggage and freight.

Surveying Minnesota Roads—Four crews are surveying in the northern part of Minnesota highways to be built under the new Ellwell law. One party is working on the projected International Falls-Twin City road, another on the Duluth-Winnipeg road, and third is at work on the Duluth-Moorhead road and the fourth on the Bemidji-Beaudette road. A concrete road is projected from Minneapolis to Hopkins on the Minnetonka highway. The Winona Automobile Association is planning to widen to 20 feet the Winona-Minnesota city road and surfacing with gravel. This stretch is 2 miles.

Automobile Incorporations

SOMERVILLE, MASS.—Caverly Automobile Company; capital $5,000. Incorporators: Irvin C. Caverly, Wm. A. Thibodeau, Edna C. Caverly.

TOLEDO, O.—Willys-Overland Company of Toledo; capital $25,000,000; to manufacture automobiles. Incorporators: Walter Stewart, Isaac Kinsey, R. R. Scott, A. H. Smith, G. W. Bennett.

TRENTON, N. J.—Lord Baltimore Motor Car Company; capital $100,000; general automobile business. Incorporators: J. Lentz, Jr., H. C. Nicholas, J. L. Conrad.

GARAGES AND ACCESSORIES

CLARKSDALE, MISS.—Montroy Ignition Starter Co.; capital $10,000. Incorporators: J. M. Montroy, C. L. Montroy, E. M. Fant and E. Fant.

CLEVELAND, O.—Victor Brass Manufacturing Company; capital $25,000; to manufacture brass articles of all kinds, including automobile parts and to operate a machine shop. Incorporators: M. T. Mahon, A. M. Fiebach, T. B. Pelton, F. M. Pelton.

CLEVELAND, O.—Presco Manufacturing Company; capital $15,000; to manufacture lamps and automobile specialties of all kinds. Incorporators: H. G. Smith, J. C. Hipp, T. J. Smith, Tony Lanness, Daniel Pfahl.

DETROIT, MICH.—Armitage Leather Company; capital $35,000; to produce leather for use in automobiles. Incorporators: W. S. Gurd, E. S. Barbour, R. B. Gillespie, Edwin Armitage.

DETROIT, MICH.—Detroit Autoheater Company; capital $3,000; to manufacture automobile heaters and other accessories.

HARRISONBURG, VA.—Harrisonburg Garage; capital $25,000. Incorporators: John H. Garber, J. J. Hawse.

INDIANAPOLIS, IND.—The New Miller Carbureter Company; capital $200,000; to manufacture carbureters and other automobile accessories, gas and gasoline motors, etc.

MINNEAPOLIS, MINN.—Northwestern Tire Company; capital $50,000; to deal in accessories. Incorporators: F. J. Kerner, A. A. Kerner, J. C. Roney.

NEW YORK CITY.—Rolaff Oil Carbureter Company; capital $25,000. Incorporators: Richard W. Olfsky, Joseph W. Stone, Wm. G. Van Vleck.

NEW YORK CITY.—United Rubber & Supply Company; capital $200,000; tire fillings. Incorporators: Herman Mayer, Thomas H. Royce, Charles L. Brookheim.

NEW YORK CITY.—Favary Tire Company, Inc.; capital $300,000. Incorporators: Ethelbert Favary, William P. Richardson and M. W. Brashears.

NEW YORK CITY.—United Rubberine Supply Company; capital $200,000; to deal in tire filling, rubber, etc., etc. Incorporators: H. Mayer, T. H. Royce, C. L. Brookheim.

NEW YORK CITY.—New York Macandaruba Tire Filler Company, Inc.; capital $25,000; to deal in a composition used for filling tires. Incorporators: Moses Haas, Nathaniel Levy and Geo. A. Weingetz.

NORFOLK, VA.—Michigan Motor Branch of Virginia; capital $10,000. Incorporators: John T. Buchanan, R. H. Baker, Archie M. Bopp.

PATCHOGUE, N. Y.—Patchogue Garage Company, Inc.; capital $1,500. Incorporators: Julian A. Udall, Jr., Harry J. Lawrence and Julian A. Udall.

PITMAN, N. J.—Campbell's Auto Express; capital $25,000; to do a general express and delivery business. Incorporators: R. Worthington, N. Koelle, C. A. Wolverton.

PORT CHESTER, N. Y.—Nelsons Garage, Inc.; capital $1,000. Incorporators: Fritz Nelson, Martins Nelson and John Colantonio.

RICHMOND, VA.—Harrisonburg Garage, Inc.; maximum capital $25,000, minimum $10,000. Incorporators: J. N. Garber, J. J. Hawse, H. L. Furr.

TOLEDO, O.—Toledo Auto Shows Company; capital $10,000; to conduct automobile shows and exhibits. Incorporators: F. L. Mulholland, A. A. Atwood, H. W. Blevins, J. W. Banting, G. R. Ford, Stanley Roberts.

WESTON, W. VA.—Ahnear Oil & Gas Company; capital $10,000; oil and gas. Incorporators: W. H. Ahnear, Lewis Bennett, H. M. Bennett, C. A. O'Hara and J. S. Vandervort.

YOAKUM, TEX.—Yoakum Machine Shop & Garage; capital $10,000. Incorporators: W. L. Orth, L. A. Orth and M. S. Orth.

YONKERS, N. Y.—Colonial Taxi Service Company; capital $3,000. Incorporators: Alfred L. Barmore, Ernest S. Miller and John L. Barmore.

YOUNGSTOWN, O.—Youngstown Automobile Show Company; capital $1,000. Incorporator: W. P. Williamson.

CHANGES OF CAPITAL AND NAME

CLINTONVILLE, WIS.—Four Wheel Drive Automobile Company; capital increased from $110,000 to $250,000.

CLEVELAND, O.—Galion Motor Truck Company; capital increased from $300,000 to $1,000,000.

RICHMOND, VA.—Stewart-Warner Speedometer Corporation; capital increased from $3,000 to $11,000,000. Incorporators: Robert Oehmig, James E. Hauronic, H. S. Perrigo, B. Flippen.

Overman Resilient Grooved Automobile Tire; Fowler Exhaust Siren; Ferromatic Automobile Tire; E. G. Bumper for Cadillac Cars; Thermic Driver's Gloves; Detroit Car Heater; J-M Keystone Radiator Shield

Overman Pure Rubber Tire

IN ORDER to overcome the shortcomings of the pneumatic tire, the Overman Tire Company, 250 West Fifty-fourth street, New York City, has constructed the Overman cushion tire, illustrated in Fig. 1. This tire is made of rubber throughout, but the latter is vulcanized only to such an extent as to still be able to absorb all the shocks encountered in traveling without the use of an inner tube. As the cross-sectional photographic view shows, the use of an inflatable tube would be impossible with an Overman tire, as rubber fills practically all the space which ordinarily is taken by casing and inner tube. This rubber forms the resilient element proper, contrary to pneumatic practice, where the rubber only serves as container and protector for the inner tube. The shape of the cross-section is rather suggestive of solid tire practice, but there are several important points, besides the high resiliency, in which this tire differs from so-called solid tires. The tread is formed as a meandering band, continuing all over the outside annulus of the tire, and the grooves formed between the windings of this relief-shaped tread afford spaces into which the rubber may expand when compressing under load. A small continuous air space of approximately triangular section is formed inside of the tire which also permits of compression of the rubber into it. A thin strip of fabric runs along this triangular space and the tire base as well as the flanges which are formed on both sides of the same. Through these flanges the tire is bolted to the wheel felloe to prevent its creeping on the metal rim and its deterioration thereby.

Ferromatic Automobile Tires

Another substitute for pneumatic tires has been devised by the Ferromatic Tire & Manufacturing Company, Kansas City, Mo. This product is called the Ferromatic automobile tire and consists of two concentric, pressed-steel rings which are arranged around the rim of the wheel and between which two helical vanadium springs are in place, which form the resilient element of the tire. In order to produce increased ease of riding the outer ring is covered with a tread of rubber vulcanized onto the steel ring and resembling the tread of a pneumatic to a fair degree. All told the appearance of the tire is a good deal like that of an ordinary outfit.

A long life is claimed for this product and this is a fair expectation due to the almost entire absence of materials which deteriorate quickly.

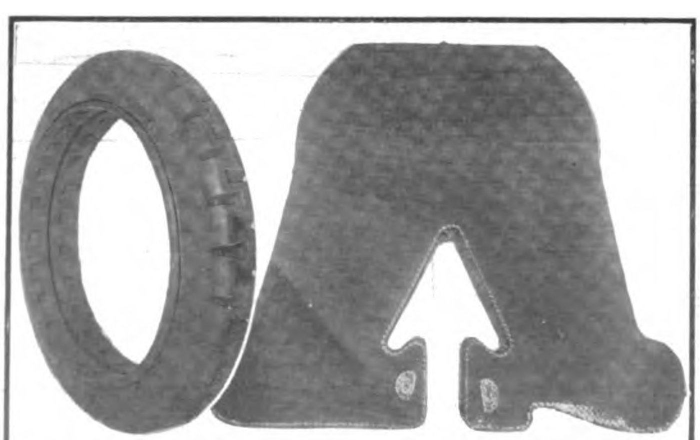

Fig. 1—Overman resilient rubber tire

Novel Spring-Leaf Lubricator

Under the name of spring-leaf lubricator a simple device is offered to the automobiling public, which is a double-wedge screw clamp consisting of a round shaft having fastened to either of its sides a solid foot and arm between which is placed a sliding jaw. The jaw has a projection making a wedge foot with a projection on the foot. By means of a cross rod, a screw which is ball jointed to the sliding jaw and threaded to the solid arm, is turned toward or away from the opposing foot. To lubricate the spring leaves, the tool is spanned across the latter. The points of the wedge teeth are inserted between two teeth and the screw is turned up until the leaves are well separated, a little oil, grease or graphite is placed in the crack and the tool removed. The tool may also be used as a temporary clamp in case of a broken leaf. This device is manufactured by the Spring Leaf Lubricator Company, Ann Arbor, Mich.

Fowler Exhaust Siren Horn

The Fowler Lamp & Manufacturing Company, Chicago, Ill., has brought out an exhaust operated automobile signal which while differing in some respects from so-called siren horns operates on a similar principle. The horn consists substantially of a tube which attaches to the exhaust pipe of the motor, being attached between the latter and the muffler. When a butterfly valve arranged at one end of the pipe is moved by the control mechanism located on the dashboard, the pipe affording access of the exhaust gases to the muffler being closed and the gases directed into the signal tube. The latter contains a fanwheel of the propeller type which is rotated by the inrushing gases and by its motion breaks them up, imparting to them a rapid whirling movement which strikes, at rapid intervals, the other end of the tube which is covered with a perforated metal sheet. The forced passage of the gases and their intermittent flow produce a sound which is rather melodious, resembling that of a siren a great deal and being rather well adapted for use as an automobile warning signal.

Winona Radialite Device

A practical headlight-turning device has been brought out by the Winona Carriage Company, Winona, Minn. This device consists of a pair of forked lamp carriers held in tubular supports which are clamped on to the front end of the chassis frame and contain the central member, which is developed into a fork further up. One of the lamp forks has its central member connected to the steering cross rod by means of a reach rod, while both forks are connected to each other. The whole system works out as follows, the reach rod being arranged at the right of the car: If the car wheels are turned to the right, the reach rod is pulled back, thereby turning both forks so that their lights face in the same direction as the wheels. If the latter are turned to the left, the reach rod is pushed forward and turns the lights in the opposite direction.

Bremer-Wilson Starter for Fords

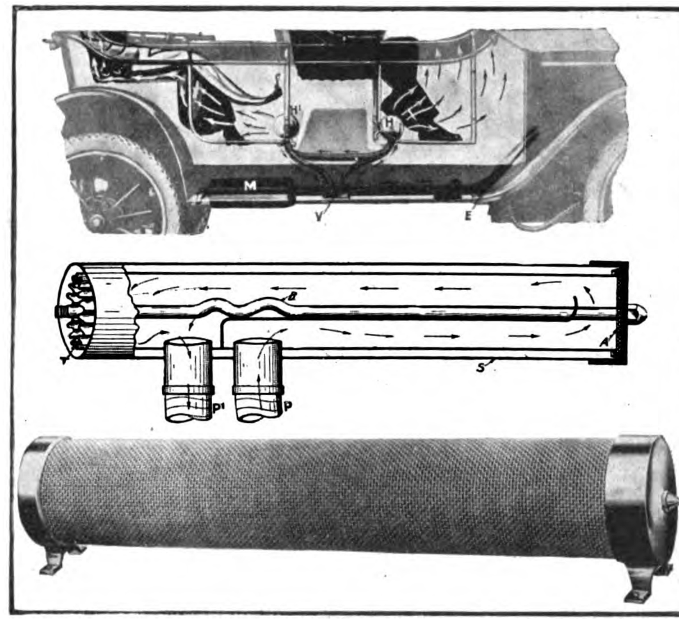
The Triplex starter for Ford cars has been placed on the market by the Bremer-Wilson Manufacturing Company, 1256 Michigan boulevard, Chicago, Ill. This starter consists of a small clutch capable of engaging the crankshaft directly in front of the dashboard if a handle is pulled by the driver. A tension spring disengages the clutch after starting.

Clamp-On Bumper for Cadillacs

The E. G. bumper specially designed to fit Cadillac cars, although it is applicable to other cars as well, is shown in Fig. 2 The bumper may be obtained with a tubular or square bar, but the method of attachment characterizing it is the same in all cases. The bar is held in the ring ends of two connector bars, each formed of a pair of telescoping tubes, the other ends of which are rigidly secured to the front end of the chassis frame and which contain the shock-absorbing springs. The clamping members which attach to the frame end are seen in Fig. 2, consisting of an approximately T-shaped stamping having on one side a downturned flange which fits over the upper leg of the channel of the frame. This flange is tapped with two screw-threaded holes, in each of which works a small screw the tightening of which secures the T-member to the frame. By loosening the screws and moving the whole mechanism along the chassis member, the position of the bumper may be changed to suit the wish of the owner, making the whole device flexible and adaptable enough, permitting of clearing the starting crank while yet affording an arrangement which protects the front of the car in case of collisions. This bumper which is furnished in black throughout, or with black fittings and brass or nickel-plated bumper bar, is made by the Emil Grossman Company, 250 West Fifty-fourth street, New York City.

The Detroit Automobile Heater

The Detroit Auto Heater Company, Detroit, Mich., manufactures the new heater, Figs. 3, 4 and 5. The same consists of a two-way valve which directs the exhaust either directly to the muffler or leads it through the heater and of the heater proper. The latter consists in turn of a corrugated, gastight pipe T through which the exhaust gas flows and which is surrounded by another pipe, an air space being formed between both. The exhaust enters through P and leaves through P1, and the whole device is inclosed in a screen which is equipped with feet, permitting of keeping the apparatus standing on the running board. The air which passes through the space between exhaust and outer pipe then flows into a manifold and to the front and rear compartment of the car, to increase the comfort of driver and passengers.



Figs. 3-5—Detroit automobile heater and parts

Electrically Warmed Driver's Gloves

One of the many new accessories which the present winter has called forth is the outfit shown in Fig. 6, the electrically warmed glove made by Carron & Company, Inc., 1784 Broadway, New York City. This invention which after being tested for a long time is now ready for the market consists of a pair of brass plates which are mounted on the steering-wheel rim and are connected to the poles of a 6-volt battery. The gloves are equipped with two button contacts which, when pressed against the two brass plates, permit a current to flow through a wire resistance laid through the glove so as to be in contact with the back and palm of the hand and to surround the fingers; the effect is that if the wire is heated, the hand and its every part is warmed to any desired degree, the heat being regulated by means of a rheostat mounted on the spoke of the steering wheel. There is a rheostat for every glove, the two of which are independent of one another, so that one hand may be warmed and the other not, or both to varying degrees. The wire resistance consists of a very great number of hair wires wound with silk so as to form a cable; so that many wires may break and yet the working of the glove remains undisturbed. On the other hand, the wires are very strong and tough, so that breakage is not a frequent occurrence and need not be considered. Of course, the plates may be attached at any portion of the steering wheel rim and their position may be changed to suit the driver's requirements. As Fig. 6 shows, the appearance of the gloves is not different from an ordinary good type of glove and there is no difference between the use of this glove and any other. Furthermore, if it is desired to stop the warming of a hand or both, it is merely necessary to interrupt the contact between one of the glove buttons and the brass plate which it touches. This shows the simplicity and usefulness of this new accessory.

The current consumption is small, being approximately .70 ampere, so that about 10 watt are needed to keep the driver's hands warmed. It might not be needless to add that cold hands in winter are not only the source of a more general discomfort, but frequently the cause of dangerous situations, as control is made very difficult if the hands are not in normal condition.

Johns-Manville Radiator Cover

Another radiator cover is out. The H. W. Johns-Manville Company, New York City, is the maker of it and has named it the J-M Keystone radiator shield. The latter consists of a thick layer of thoroughly cleansed cattle hair, neatly quilted between two layers of waterproof imitation leather. The edges of this waterproof covering are folded over and securely stitched together along all four edges of the cover, while the entire surface of the same is quilted through and through só that it will permanently retain its heat-insulating qualities. The center of the shield is arranged as a flap folding toward the top, being capable of closing by means of two snap-hooks so as to cover the entire front of the radiator when the car is not running. The shield does not absorb water, oil or grease and can be easily cleaned when soiled. It will not scorch or burn and is neat in appearance. Attachment of the shield is by rawhide straps and rings which fasten to bottom and sides of the radiator, while an adjustable straphanger is provided for fastening over the filler cap. A round spring wire is securely fastened at the top edge and inside the covering of the Keystone shield to hold it in shape.

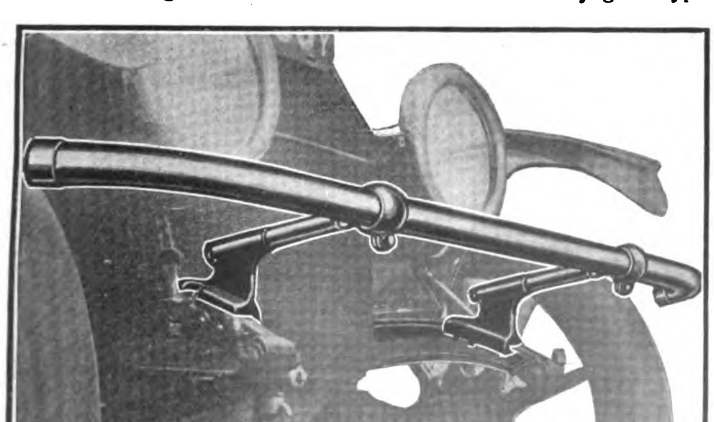


Fig. 2—E. G. clamp-on bumper for Cadillacs

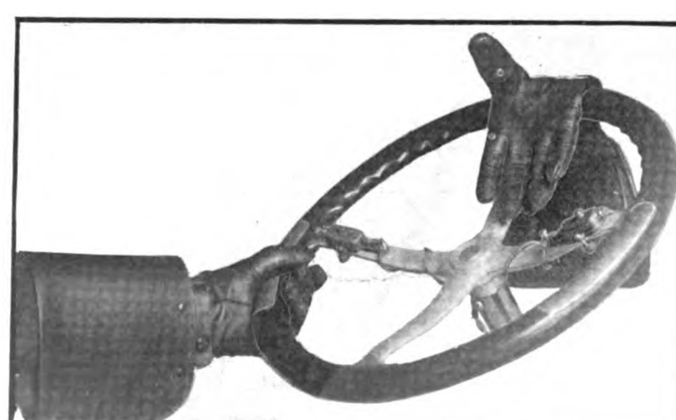

Fig. 6—Electrically heated driver's gloves

INTERNAL Combustion Motor—In which a separate piston is employed to compress air in the crankcase for subsequent use in the combustion chamber.

The two-cycle motor described in this patent and illustrated in Fig. 1 is distinguished by the use of a piston working in a cylindrical extension of the crankcase which is located adjacent to the working cylinder. The piston P1 is fixed to a connecting rod pivoted at the center of a walking beam W, one end of which is attached to the crankcase wall and the other to a special connecting rod C1 carried by the piston and being independent of the ordinary connecting rod which works on the crankshaft. The working piston and the air compressing piston P1 work in parallel, that is to say they both move up or down at the same time due to the walking beam arrangement. When the main piston is on the explosion stroke it moves P1 down whereby air is compressed in the crankcase in addition to the action of the working piston and is forced through to transfer passage T to the inlet port which opens when the piston reaches the bottom of its stroke; at the same time the dead gases are expelled through the exhaust port E. After the inlet port has been closed by the piston the suction caused in the crankcase by the upward movement of the pistons opens the valve A in the side of the crankcase and air enters through it, whereupon the cycle is repeated as described above. Fuel is injected by way of a sleeve valve F in the head of the cylinder so that a rich mixture is obtained in the proximity of the spark plug S. This fuel injector valve is operated by the armature A1 of a coil C which is energized periodically by a current timed in the ignition distributer of the motor.

No. 1,046,491—to Alfred Randolph, Salem, O. Granted December 10, 1912; filed August 24, 1910.

Automobile Tire Mail—Comprising a mantel of chain links embedded in the fabric of a tire to prevent skidding of the same.

The subject matter of this patent is seen in Fig. 2 and consists of means for connecting the links of the chain embedded in a tire in such a manner as illustrated. As Fig. 2 shows the chain system extends all the way across the tire down to the beads on both sides. The device is constructed in the following manner: The links of strands longitudinal of the tire are crossed by transverse strands; the links are of single sheet-metal stampings and each link of the longitudinal strands is inclosed on one leg by the half of the superimposed transverse chain link. These chains are vulcanized on the tire and while they reinforce the casing they do in no way interfere with the flexibility thereof.

No. 1,046,451 to Joseph B. Duhring, Chestnut Hill, Pa. Granted December 10, 1912; filed December 15, 1911.

Piston-Valve Construction—A small piston works in an auxiliary cylinder in the head of the working cylinder of an internal combustion motor.

Fig. 3 shows the subject matter of this patent, namely, a piston valve which controls the exhaust port of an internal-combustion gasoline motor. This piston V works in a small cylindrical extension formed on top of the working cylinder. The piston is controlled by the pressure in the cylinder on one hand and the tension of the spring S connected to the auxiliary cylinder and the crank C which carries the small connecting rod operating the piston rod V. Normally the spring holds the piston V in a position off dead center; if the pressure in the cylinder exceeds the tension of the spring the latter is compressed, the piston is moved outwardly while in case of reversed conditions the piston moves inwardly thereby controling the exhaust port of the cylinder.

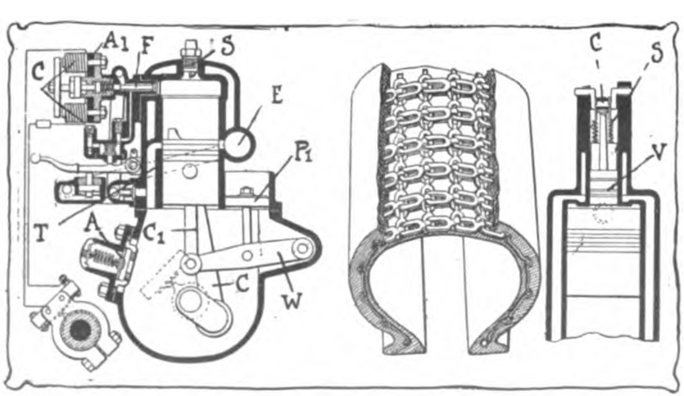

Fig. 1—Randolph two-cycle motor. Fig. 2—Duhring tire mail. Fig. 3—Butsch piston-valve

No. 1,046,965—to Alphonse Butsch, St. Lucia, British West Indies. Granted December 10, 1912, filed October 1, 1909.

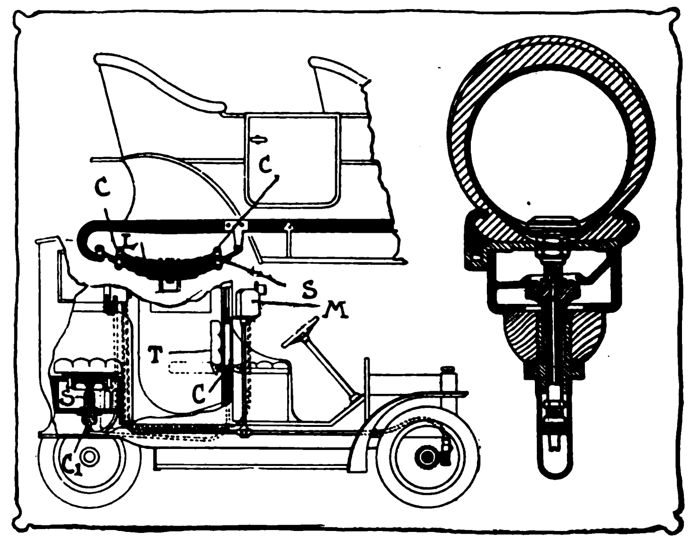

Fig. 4—Kaunitz rebound-check spring. Fig. 5—Kuhn-Netter taxicab control. Fig. 6—Booth tire valve

Rebound Check Spring—Comprising a semi-elliptical construction which is mounted inside the arch of the main elliptic spring.

This patent refers to an anti-rebound spring L which consists of a short leaf spring mounted on the inner side of the master leaf of the regular suspension springs of a car. The spring L is secured to the regular spring S by shackles fastened to clips which go over the main spring. It is easily seen that normal action of the spring S is not restricted but that a recoil which tends to increase the arch of the spring S is counteracted by the initial tension of the spring L.

No. 1,044,661—to Nils W. Kaunitz, Hoquiam, Wash. Granted November 19, 1912, filed December 9, 1911.

Automatic Taxicab Control—To record number of passengers in a car.

This invention is illustrated in Fig 5 and consists in the use of a clutch C which connects the auxiliary seat T of a taxicab to the taximeter mechanism in such a manner that if the seat T is tilted down for the use of a third passenger the clutch is thrown in and a record is made on the taximeter. A similar clutch arrangement is used by the main seats, clutches C1 being engaged if the seats are pressed down by the weights of passengers.

No. 1,046,808—To Max Kuhn and Raphael Netter, New York City. Granted December 19, 1912; filed August, 26, 1911.

Tire Valve Connection—Consisting in a valve piece fitted into the rim which forms a continuation of the tire valve proper.

This invention is illustrated in Fig. 6 being a supplement to the valve of the inner tube which fits into it and forms a complete valve ready for inflation purposes when the tire is on the wheel. The construction shown in the illustration is such that the use of such a valve greatly facilitates the replacing of a tire on a demountable rim.

No. 1,044,435—To William N. Booth, Cleveland, O. Granted November 12, 1912; filed June 2, 1911.

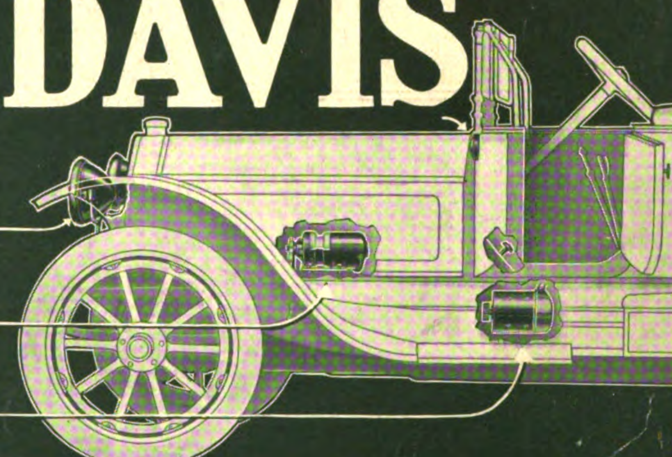
Quality Equipment for Automobiles

GRAY & DAVIS

Electric Lamps

Lighting Dynamo

Electric Starter



An automobile equipped with one or all of the Gray & Davis products offers maximum safety, efficiency and convenience. Such a car may be purchased with the knowledge that the manufacturer has spared no expense in his effort to produce the highest type of automobile. Cars carrying Gray & Davis Lamps, Dynamo or Electric Starter are good cars to buy!

ELECTRIC LAMPS

Gray & Davis Electric Lamps are the result of 16 years of lamp-building experience and are constructed in a great factory equipped with the most modern machinery. They are lamps of Quality. They produce the most brilliant light, are strong and sturdy, and enhance the value and appearance of any automobile. If you seek handsome lamps, capable of giving penetrating illumination, specify Gray & Davis Electric Lamps.

LIGHTING DYNAMO

The Gray & Davis Dynamo lights the lamps irrespective of the condition of the battery. It possesses the Constant Speed feature which insures unvarying, constant voltage. This Dynamo lights lamps, charges batteries, provides current for power-horn, speedometer light and electric starter. It saves cost for recharging batteries and gas tank. All you have to do is turn a switch on the dash.

ELECTRIC STARTER 6 volts

The Gray & Davis Electric Starter is a marvel of simplicity. No complicated controls—only a simple switch. It requires only the usual 6 volt battery, which is charged automatically by the dynamo. It starts a car under any conditions. It is a specially designed motor which rotates the fly-wheel—pressure on a pedal starts the engine. It will spin a 6-cylinder car for one and one-half hours—propel it 2 miles.

MERCER

ANNOUNCING

Type 35, Series G, Four-Passenger **Type 35, Series H, Five-Passenger**
Type 35, Series J, Raceabout **Type 35, Series K, Runabout**

A NEW series of Mercer cars that appeal directly to the Motorist who realizes that bulk and weight are no longer essential in a motor car of the highest type. The Mercer is the "happy medium" car—neither too heavy nor too light.

Power, strength, durability, consistency of performance, comfortable riding qualities, graceful appearance, up-to-the-minute appointments, and real legitimate dollars-and-cents value, are what influence wise buyers in their choice of a car. Measured by this standard the Mercer is recognized as leader of the medium-weight class.

Pronounced features are high efficiency motor, perfect lubricating system, reliable steering gear, large and perfectly balanced crank shaft, four-speed transmission, foot brake operating on transmission, springs that give real riding comfort, two-spark Bosch magneto of enclosed type, Rushmore electric lighting and starting systems, both separate units and operating independently of ignition, distinctive and exclusive body designs.

Prices: $2600 to $2900

The

Truffault-Hartford SHOCK ABSORBER

is *regular equipment* on most of America's best cars.

These factories first determined that their purchasers wanted it. Next, they set out to satisfy themselves that *they* wanted it. Then began the most exacting of all tests—a series of factory tryouts. The laboratory men had the first inning; they sought for possible defects in materials or workmanship. The mechanical engineers had their turn; they sought for flaws in principle or construction. Last of all came the road tests: these extended to every kind of road imaginable.

If there was anything wrong with the device, these experts would surely have discovered it, but the chemists, engineers and other wise men of these factories passed judgment on the Truffault-Hartford Shock Absorber and pronounced it *indispensable*. That's why it's regular equipment on their cars and broadly advertised as such. Factories always *prove* before they adopt.

Aside from factory test, the best line you can get on Truffault-Hartfords is to ride in a car equipped with them. This will convince you that they "make every road a boulevard." More than that, they save tires a world of wear and tear, car from road racking, springs from breakage and in so doing *cut upkeep cost* and *double comfort*.

Equipment simplified by blueprints of every known make, model or year of car.

Cars for Sale

AUTOMOBILE—FIVE OR 7-PASSENGER touring car; good condition. No. 1924 Pleasant St., Cincinnati, Ohio.

A CADILLAC 1911, FIVE-PASSENGER touring car overhauled, and equipped with top, speedometer, wind shield and other extras. Has had the best of care and is exceptionally good proposition.
DeLamater-Byrnes Automobile Co.,
10 West 60th St., West of Broadway.

A FEW RARE BARGAINS.
Packard 1912 six cyl. touring.
Hudson 1912 "33" touring; bargain.
Renault 1911—35 gunboat.
E M F 1912—30 touring.
Stearns 30-60 touring, $700.
Buick Model 10—equipped.
Town Car, Hotchkiss Landaulette.
Lozier 1910 touring; bargain.
E. T. Scudder & Co., 1926 Broadway.

A WHITE 30 FORE-DOOR GASOLINE 5 passenger 1910 touring car, equipped with top, windshield, speedometer, clock, lamps, gas tank, trunk rack, tools. Driven only 7000 miles. In first-class condition. Price, $850. Address Box 60, care The Automobile.

CARS FOR SALE—IF INTERESTED IN two, four or six-passenger Underslung American used cars, in A1 condition, address "Underslung," care The Automobile.

COLE, MODEL CC., FOUR-PASSENGER, fully equipped, top, windshield, electric lights and horn, $125 Stewart tachometer, 37 x 4½" tires, extra tire, chains, etc. Painted white, striped in brown to match brown Spanish upholstery. Car has run less than 8,000 miles. Special reason for selling. Price, $1000.00. P. O. Box 596, Indianapolis.

COLE, MODEL DD 1912, SEVEN PAS-senger, fully equipped, top, windshield, speedometer, two extra casings, inner tubes, electric lights, etc. Car has run less than 6,000 miles; good as new. Special reasons for selling. Price, $1100.00, F.O.B. Indianapolis. Guaranteed as represented. P. O. Box 596, Indianapolis.

COLE 1912 40 PHAETON.
Peerless 1911 40 Limousine.
Isotta 1912 20 Limousine.
Pierce 1910 6-36 Touring.
Packards.
1910 30 Touring, with 1911 body.
1912 30 Phaeton, 1909 30 touring.
GEORGE LAMBERTY,
Bryant 8224-5. 1531 Broadway.

FOR IMMEDIATE CASH—REBUILT POPE Hartford, Elmore and Chalmers. Full information and prices on request. Also second hand Rainier $100, Thomas $450, Ford 2-cylinder $75, Maxwell runabout $125, Rambler 2-cylinder delivery $125. E. S. Youse Company, 46 N. 5th St., Reading, Pa.

FOR SALE—PALMER-SINGER 6-60 MO-tor and transmission complete, in good condition. Dr. Fryer, Riverside, Wash.

SAMSON LEATHER TREAD TIRES

have been used for the past ten years and have proved a success. Made from only the best French Chromo Leather (Deer Hide), rivetted with hard steel rivets and vulcanized on tire by Samson Patent Process, the leather going down to the bead, absolutely insures against punctures, blowouts and skidding. The additional cost of Samsonizing pays for itself in prolonging to double and treble the life of the tire, makes riding safe and easy without loss of time and trouble wasted on so called non-skid devices. H. Phillips Rubber Works, 1931 Broadway, New York; 'Phone 9066 Col.

"THE ORIGINAL AND BEST ASBESTOS BRAKE LINING"

Than Ever Before in the History of the Industry

Manufacturers, dealers and owners now realize that this is *the* lining which made the automobile safe. That is why it is demanded by all motorists who insist upon safeguarding their lives against accident. RAYBESTOS *stops* car without effort and in time to avoid danger.

Be Sure to See the Royal Equipment Co. Exhibit at the Show

Examine RAYBESTOS. See for yourself why it is better than any other lining—note the material, the close, compact weave, the strong, sturdy toughness—the special treating and all the things that make it the best.

DUPLEX BRAKE—the brake that stops the car instantly, whether it is going forward or backward, will also be on exhibition.

If You've Had Brake Troubles

write us or call at the show. We'll be mighty glad to give any assistance. We are brake experts, build brakes to order, make enormous quantities of brakes each year and are in a position to help you to make *your* car safe.

The Royal Equipment Co.

420 Housatonic Ave., Bridgeport, Conn.

SAVE YOUR TIRES

Examine your tires carefully and notice the thousands of little breaks, some no bigger than a pin prick. These are the beginning of decay. If you want your money's worth out of those tires stop the decay now. You can do it by applying Preserv-O Tire Paint. It fills every little break and covers the whole tire surface with a coating of pure white waterproof rubber. It dries quickly, cannot hurt the tire, and lasts longer than any other tire paint. Let us ship you a can express prepaid. Money back if you ask it. Send 50 cents (or a $1 bill for two cans) today. Made and guaranteed by the Tire-Doh people.

ATLAS AUTO SUPPLY CO., 75 E. ADAMS ST., CHICAGO, ILL.

How to Repair an Inner Tube in 15 Minutes

Directions: Place tube between plates of the **Imperial Vulcanizer** (see cut); tighten thumbscrews; put a little gasoline in pronged receptacle; ignite. A permanent repair in 15 minutes.

You can do this yourself at home or on the road—anywhere. The Imperial Vulcanizer saves time, saves money, is easy to operate, and pays for itself in a short time.

NICKEL PLATED **PRICE $3.50** Patent Pending

Complete with enough rubber for 40 punctures. At your dealer's or sent by express.

Guaranteed to Satisfy or Money Refunded

McGRAW TIRE & RUBBER CO., Dept. D, **East Palestine, O.**

Where's Your "Six" for 1913?

Every progressive manufacturer announces a "Six" for 1913. The supremacy of the "Six" is established. It has come to stay. Sooner or later you have *got* to add a "Six" to *your* line. Competition will force you to it. Why not *now?* Your 1913 "Six" at from $1600 to $2000 will prove a self-seller if equipped with a

Beaver "Six" Unit Power Plant

With cylinders 3¾ x 5 inches this motor has the much desired long stroke and just the right power—40-45 H.P. Valves are extra large and the enclosed valve action is noiseless. Transmission unit enclosed with motor has plate clutch and 3-speed forward selective sliding gear-set. Write for catalog of motors and prices.

BEAVER MANUFACTURING CO.

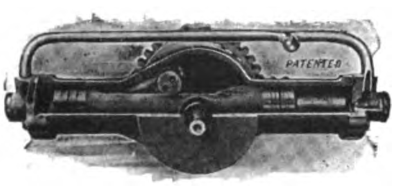
O. B. GEAR DRIVEN AIR COMPRESSOR

This compressor runs equally well placed in any position

Why are other compressors discarded in favor of the O. B.? There is a reason. Examine the sectional cut and you will readily see why this compressor will last a lifetime, needs no attention, compress air way above usual requirements, has very few moving parts, and is constructed on right principles, which are covered by patents. We use piston rings and bevel seated valves (notice piston rings in one end and piston ring grooves in the other). Can you find all these features in other compressors?



Patented August 30, 1910. Other Patents Pending

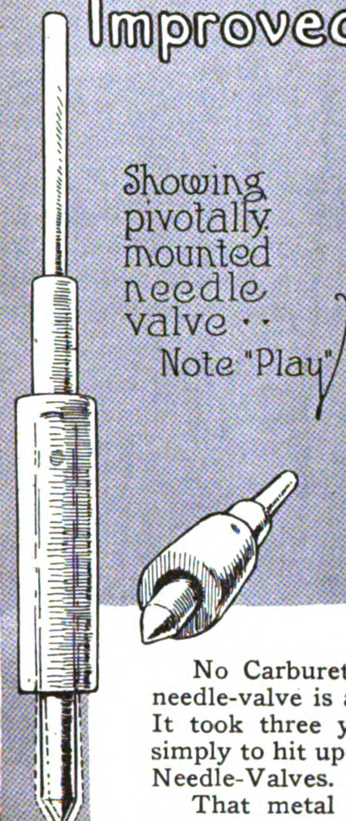
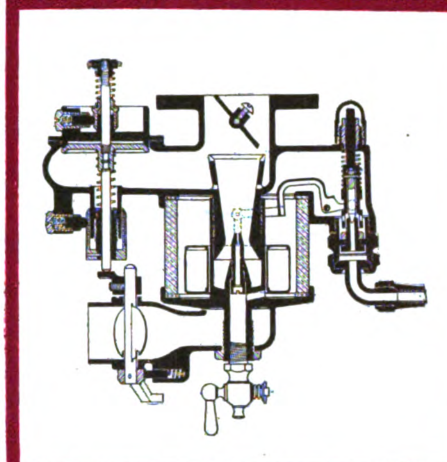
Sixty Years of Successful Manufacturing

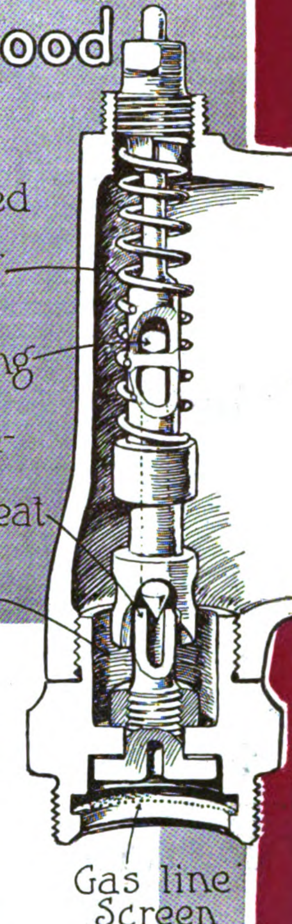
WHY STROMBERG

Improved Carburetors Won't Flood





SECTIONAL VIEW OF MODEL B



No Carburetor is more efficient than its needle-valve. A "sick" needle-valve is at the root of as much flooding as a "dropsical" float. It took three years' experimenting in STROMBERG laboratories, simply to hit upon a metal from which to manufacture STROMBERG Needle-Valves.

That metal had to withstand all vegetable acids—it must not rust nor corrode. That metal had to be as hard as a diamond—it must take a polish as smooth as glass—in long periods of service must not "blunt" nor wear—under the severest vibrations must not "groove" nor vary in points of contact. Such are qualities of STROMBERG Needle-Valve metal.

STROMBERG *Improved* Carburetors won't flood because their needle-valves are self-cleaning, self-aligning, adjustable. Why? Because they are pivotally mounted. They are self-cleaning because they have plenty of "play" (see illustration), resulting in any possible obstruction being "joggled" out of the aperture.

Being pivotally mounted, the valve has got to align. Were it possible for the valve-seat to wear, the needle-valve must adjust itself to conform to the contour of that seat—it has got to come central.

But the valve-seat won't wear. Why? Because it is made of the longest-lived valve-seat metal obtainable—exclusively manufactured from a formula determined in our own laboratories. A limit to its endurance has yet to be discovered.

STROMBERG *Improved* Carburetors won't flood because of the gas-line screen (see diagram). No foreign substances in the gasoline can "get to" the needle-valve and obstruct it unless they can worm through this fine-mesh screen. STROMBERG was the first carburetor to use a screen of this kind in the gas line.

Should foreign particles, by any possibility, get by this outer safe-guard in the Model B carburetor, they are sloughed off by the self-cleaning valve and deposited in the catch basin (see diagram) where they become harmless.

STROMBERG *Improved* Carburetors won't flood because each individual part is as delicately attuned to the whole, as the components of the most sensitive scientific instrument. The spring (see diagram) is made of specially imported steel wire, and is given a separate tension test on every carburetor assembled.

These are but a few "reasons why" it is mechanically impossible for STROMBERG *Improved* Carburetors to flood. More will appear next week.

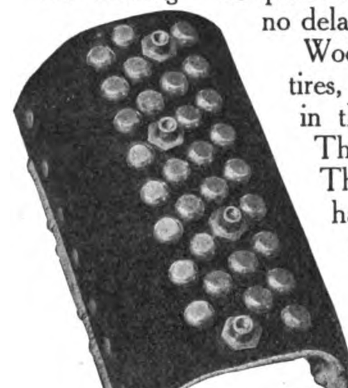
DON'T SKID!

—but save the cost of chains by using the modern non-skids for snow and ice

Double Grip *Woodworth Treads*

No bother putting on and off—they stay on all the time.
No banging of loose links.
No chafing—no punctures—no frost-bitten fingers—no delays.



Section of Double Grip Woodworth Treads showing special high rivets.

Woodworth Treads *protect* the tires, and save more than their cost in the added mileage they give. They cost *nothing* in the end. The Double Grip Woodworths have a special series of high rivets giving perfect traction in snow and ice. Put them on *now*, while your tires are still good!

Leather Tire Goods Company
NIAGARA FALLS, N. Y.
New York Store, 1608 Broadway
Good Agents Wanted for Unoccupied Territory

Guaranteed 5000 Miles Without Puncture

Whether Your Tires Are New or Old

If your tires are tread-worn or rut-worn, don't throw them away or you'll throw away $50 to $200. *Durable Treads* will make your tires wear 10,000 miles instead of 5,000.

OUR WRITTEN GUARANTEE

With *Durable Treads* we will give you a written legal Guarantee for 5000 miles without puncture. This is binding whether your tires are new or old, tread-worn, rim-cut or rut-worn.

Durable Treads are the only protectors built to actually protect your tires against rim-cuts, rut-wear and side-blow-outs.

NO MORE PUNCTURES

Your tire expense this winter will be tremendous. Frozen rough roads will puncture and ruin your unprotected tires.

But if you will protect them with *Durable Treads* you can travel over the worst roads—there'll be no punctures, road-delays, skidding or tire expenses.

And each season you will not need to pay $50 to $200 for a new set of tires. *Durable Treads* will capacitate your old ones for 5000 miles more without puncture.

Durable Treads

COST HALF OF TIRES

A set of tires cost $50 to $200. But *Durable Treads* cost less than half these amounts. Hence, isn't it economy to *protect* your tires? And isn't it more economical to buy *Durable Treads* at *half* the cost of tires?

SPECIAL DISCOUNT

If *Durable Treads* are not already represented in your territory, we will make shipments direct to you from factory and allow you our *full dealer's discount* on your initial order and make you an exceptional dealers' proposition.

TEST AT OUR EXPENSE

We want you to know just what *Durable Treads* are before you invest a cent or promise to buy. So we will ship you a pair or full set with your permission, for inspection. *We will pay all express charges.* This examination will cost you nothing. We want you to send the coupon below for conclusive proof. If you live *East* of the Mississippi, address *Chicago; West*, address *Denver*.

Last call for the Show Issues

FORTY thousand motor owners and motor dealers are waiting for the big Show numbers of THE AUTOMOBILE and MOTOR AGE.

The show issues are part of the show itself—a compact digest of everything the industry has produced in the past year.

These forty thousand intelligent and motor-wise readers will be unusually *interested* in the Show issues.

They will *absorb* them from cover to cover.

They will *keep* them and refer to them as they would to a directory.

Model B Speedometer with Grade Indicator . . . **$50**

Model B-1 Speedometer with Grade Indicator and Clock **$85**

Out of 158 Car Makers who have selected the magnetic type of speedometer for equipment on their cars, 134 have selected the Stewart Speedometer.

The Selection of the Stewart Speedometer by this great majority of car makers signifies only one thing—***that the Stewart Speedometer is an instrument of superior merit.*** Think what this means! The Stewart Speedometer is the almost unanimous selection of car makers—***men who are especially competent to judge of the merit of a speedometer***—inventors, designers and manufacturers of fine mechanism themselves. Even if you didn't know that the Stewart Speedometer is a magnificent instrument—strong, lasting, accurte, beautiful—you could safely rely upon the judgment of 134 car makers out of 158.

Therefore, if you desire permanent satisfaction insist on getting the New 1913 Stewart Speedometer with Grade Indicator when buying a car. The chances are that the car of your choice will bear the Stewart Speedometer as standard equipment ***because over eighty per cent of the total output***—ALL MAKES—for 1913 will bear the Stewart Speedometer as standard or special equipment. ***Even if the car you select is not so equipped you can get the Stewart Speedometer if you insist.*** The maker or dealer will gladly and quickly put one on—all you will have to do is to say: "I want the New 1913 Stewart Speedometer with Grade Indicator on my car."

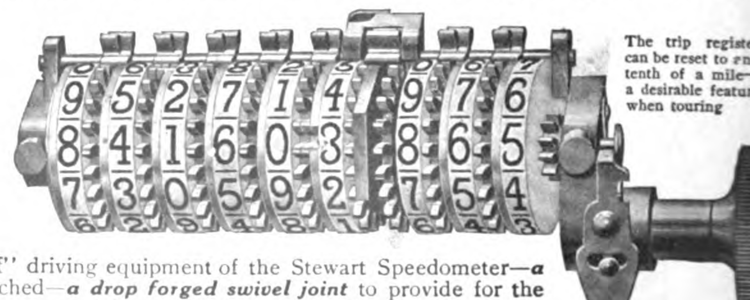
And you can rest assured that you will be right because you will have the trained judgment of one hundred and thirty-four car makers to back you in your choice.

The Grade Indicator

(At Top of Speedometer Dial)

The Grade Indicator is an accurate instrument operated automatically by gravity. Made strong and dependable, it is as unfailing as the power which operates it. It tells the exact truth about grades. It shows the various degrees of grades from zero up to thirty—the big, easily read numbers being carried on a revolving cylinder which presents the proper figure at the opening of the speedometer dial.

A Real Automobile Odometer. This Big, Sturdy Distance Recorder is Combined with the Stewart Speedometer



The trip register can be reset to any tenth of a mile—a desirable feature when touring

Note its big, honest figures—its sturdy frame—and strong brass cylinders—***that means real "instrument" construction.*** Note that ti is an expensively made ***automobile*** odometer—not a cheap ***bicycle*** odometer. Every turn of the front wheel is registered because its brass cylinders are revolved by a ***direct drive mechanism***. It cannot lie because it contains no springs to break or weaken—no pawls to slip or fail. Hard bronze gears—solid brass cylinders—direct drive mechanism—positive action—service everlasting.

Don't forget the strong, unbreakable, "trouble-proof" driving equipment of the Stewart Speedometer—***a flexible shaft*** that will outlast the car to which it is attached—***a drop forged swivel joint*** to provide for the movement of the front wheel in turning corners (others use a cast joint)—***noiseless front wheel gears.***

You can get the New 1913 Stewart Speedometer with Grade Indicator on any make of car if you insist.

$985 *Completely Equipped*

Overland

$985 *Completely Equipped*

High-priced feature No. 9

Every Overland motor is thoroughly "worn-in" on the block under a belt for 48 hours; it is then tested on the block under its own power for 48 hours.

Not content with these tests, we require that each chassis be tried out on country roads—carrying a test body weighed with 800 pounds of sand bags.

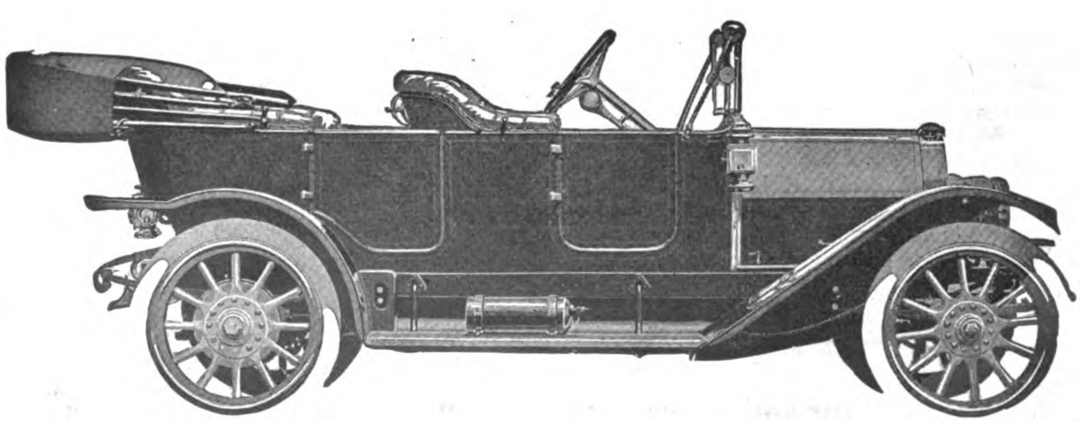
Finally, each completed car is subjected to a trying 5-mile drive by an expert driver.

When you buy an Overland you are buying guaranteed performance.

In the Model 69T this high priced inspection and supervision costs but $985.

Write today for details. Please address Dept. 38.

The Willys-Overland Company
Toledo, Ohio



Prest-O-Starter

Starts your engine (old or new) quickly and easily in coldest weather

For Four Cylinders $20

For Six Cylinders $25

$1.50 extra for two-way valve necessary when the same Prest-O-Lite is used for both starting and lighting.

Here's a starter that adds practically no weight to your car, is perfectly simple and is as durable as the engine itself. Easily applied to any engine, old or new, very economical in the use of gas, and requires no expert repairing.

How Prest-O-Starter Works

The principle of starting a motor with Prest-O-Starter is the same as "starting on compression." A measure of acetylene, at low pressure, is pumped from your Prest-O-Lite into the cylinders.

Touch your spark—your engine starts.

Unlike "gasoline priming," it is not affected by heat or cold. It is certain.

In cool weather, by opening a valve on the dash, you can feed gas at low pressure into the intake manifold. This allows your engine to run on acetylene until it is warm enough to run on gasoline.

If the Prest-O-Starter did no more than prime your engine in this way during cold weather, this convenience would be well worth the price.

But Prest-O-Starter is more than a primer. When installed properly, it will start your engine, summer or winter, almost invariably without recourse to the crank.

Make Sure Your Starter is Installed CORRECTLY—Look it Over

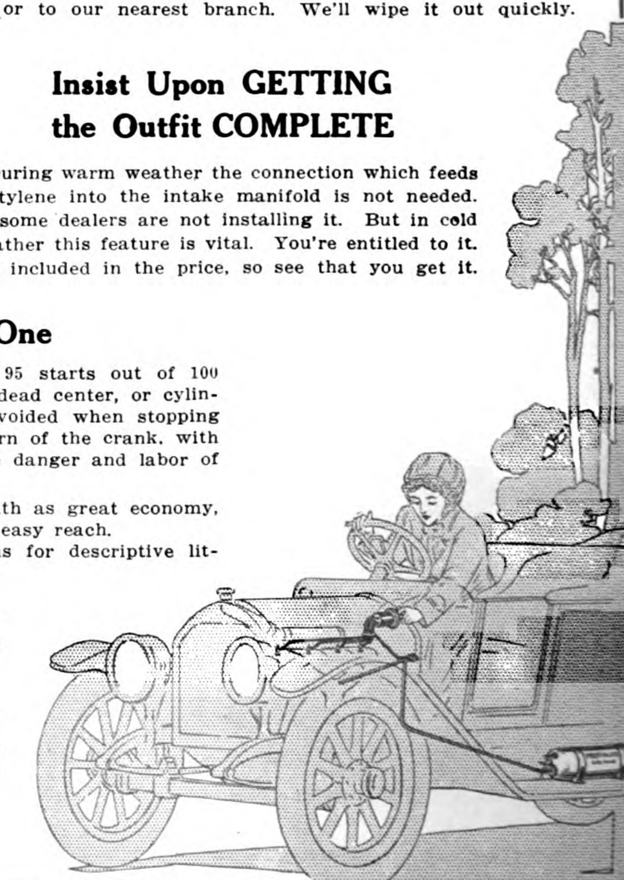
The Prest-O-Starter is easy to install correctly. In fact, it's so very easy to install that some good factories and garages install it with utter carelesslless, overlooking the one or two simple features vital to success in operation. Fortunately this is an easy matter for the car owner to correct, even if he isn't a mechanic.

Our literature tells you exactly how the Prest-O-Starter is installed, and how to adjust it. Anyone can give it the slight attention it may need or quickly tell a dealer where the trouble lies.

Every Prest-O-Starter is sold with the assurance of satisfactory service. The entire Prest-O-Lite Organization is back of every one. If you have any trouble, report it to us or to our nearest branch. We'll wipe it out quickly.

Insist Upon GETTING the Outfit COMPLETE

During warm weather the connection which feeds acetylene into the intake manifold is not needed. So some dealers are not installing it. But in cold weather this feature is vital. You're entitled to it. It's included in the price, so see that you get it.



Now—More than Ever—You Need One

Your Prest-O-Starter, properly installed, will average better than 95 starts out of 100 attempts. The few failures are caused by your motor stopping on dead center, or cylinders filled with burnt gas. Both of these conditions can be easily avoided when stopping your motor. But should either or both happen, an eighth or quarter turn of the crank, with the switch at neutral, will remedy the trouble at once, with all of the danger and labor of cranking eliminated.

Rest assured that no other starter can give you as high efficiency with as great economy, durability and freedom from mechanical trouble. The price is within easy reach.

Get in touch with any of our branches—or your dealer—or write us for descriptive literature.

Exchange Agencies Everywhere

?
WHICH

FOR EVERY CAR OWNER the question gets right down to this alternative: *damage* or a *Conover Safe-Guard.*

EITHER is inevitable.

COLLISION you *cannot* avoid. If you don't run into something, some other car or wagon backs into you. It is merely a matter of time for *every* car. Fenders, lamps, radiator, wheels, axle—any or all will be smashed to some extent. If badly, you can collect insurance; but you lose the use of your car while repairs are being made. If slightly damaged, you cannot collect a dollar.

The CONOVER
"The Dependable Safe-Guard"

PROTECTION you *can* have. And this for the original price of *one* Conover. Made on a new principle; backed by a new guarantee. Its broad, flat surface, sturdy semi-elliptic steel springs, with four contact points, were made to take blows. If dented, you can hammer back the protection surface. If broken, you can have a new Conover *free*, any time within two years.

WHICH alternative? Which is the economical, satisfactory sensible one?

Best quality of steel heavily enameled in black, royal blue, French gray or maroon; bar 2 inches wide. **$15.00**
(Any other color of enamel $5.00 extra)

Best quality of steel, brass or nickel plated; bar 2 in. wide - - - **$17.50**

Solid bronze, finished in either brass or nickel; bar 2 in. or 2⅜ in. wide **$25.00**

Shipped, express paid, anywhere in the United States, on thirty day's trial, upon receipt of the regular price. When ordering, give name and model of car. Specify size and finish desired.

An attractive booklet will be sent free upon request.

IF YOU ARE IN DOUBT AFTER TRYING IT, WE WILL NOT ONLY GIVE YOU YOUR MONEY BACK, BUT WILL GIVE YOU A NEW SET OF TUBES.

It Is Time to Give Up Tire Changing

Airease absolutely does away with roadside Tire Repairs!

Motoring to-day would be the great national pleasure if it were not for that ever-present bug-bear—TIRE TROUBLE. The most disagreeable part of motoring is completely eliminated by the use of a tire filler that makes tires as resilient as air, yet as unpuncturable as solid tires.

Reflect on some of your past experiences: changing casings in the boiling sun, pumping tires under torrid heat, changing tires at night or in the rain, or going home on the rim—ALL of these are relegated to the region of the old "one-lung" and two-cylinder opposed motors.

WISE MEN MARVEL today at the fact that the old-time bicycle tire, with its troublesome compressed air, could have developed into the automobile tire. Thousands of attempts have been made at spring wheels and airless tires, and not a few tire fillers have been marketed. But it remains for Airease to produce a lasting, unchangeable material, not affected by heat or moisture, or cold or drought, that will be as resilient as air and an indestructible element in itself.

Nearly every car owner has said unprintable things about his tires, while dealers and garage men have been besieged with requests for a cheaper and satisfactory substitute for the tire filled with air.

After many years of investigation by a famous chemist, and three years' experimentation and use on many cars, that substitute for air has been developed not only to a marketable state, but to an almost perfect one. In fact, Airease fills all the requirements of the perfect tire filler.

The AIREASERS demonstrating the joys of care-free motoring

CAN IT BE THAT THERE IS A MAN IN THE WORLD who would insist on using compressed air in his tires if he were sure that a perfect tire filler could be quickly put in them which would give all the resiliency of air and last for many years?

A PORTRAIT OF THE INVENTOR

All-Year-Around Service

TO GET full value from your motor car you should select one which is suitable for all - the - year - round service.

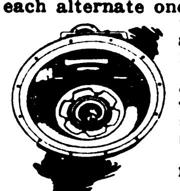
Abbott-Detroit automobiles are.

In the first place, they are driven by powerful Continental motors which have sufficient reserve power to meet all emergencies.

Each unit conveying the power from the flywheel to the wheels is an equally efficient mechanical device. Practically no power is lost.

THE CLUTCH

The clutch which is of dry, multiple disc type is composed of 17 steel discs, each alternate one faced with a combination of copper wire mesh and asbestos which will not burn.



Interior of Fly-wheel Case Showing Multiple Disc Clutch.

When this clutch is operated, there is a total absence of all gripping, jarring and jumping, the motor taking hold gradually but firmly.

Owing to the large amount of friction surface, this clutch is most efficient and may be slipped without harm or excessive wear.

Those who have driven cars, through heavy mud and winter snows, know how valuable is this ability.

Another thing, in the cone clutch, the revolving part attached to the transmission is so large and heavy that the inertia of such a mass of metal tends to keep the clutch in motion and renders it almost impossible to shift the gears readily; without producing that clashing and rasping noise so disagreeable to the occupant of the car and others nearby.

Transmission and Clutch Unit with Inspection Covers off.

In the multiple disc clutch, however, this inertia is reduced to a minimum and the gears may be shifted while the speed of the car is being reduced or accelerated, without the attendant disagreeable and deteriorating effects.

It wears very little and seldom requires adjustment.

Abbott-Detroit advertising for 1913 is being printed in serial form. This is the sixth of the series. The seventh will appear in Saturday Evening Post January 18, 1913, Collier's Weekly January 11, Life January 9, Literary Digest January 4. Copies of previous advertisements sent on request.

THE TRANSMISSION

The transmission, which is of the three-speed forward and reverse sliding gear type, is situated just behind the clutch and its case is bolted direct to the engine crank case, so that the whole power plant forms one unit.

The main shaft and countershaft gears, the faces of which are 1 inch in width, ¼ of an inch wider than those usually used in other cars of this class, are made of 3½ per cent. nickel steel, very accurately machined, ground and mounted upon Timken roller bearings.

The transmission and clutch case is oil and dust-proof and the gears and shafts run in a specially prepared lubricating compound.

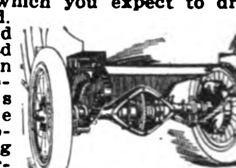
If desired, the interior of the transmission case may be easily inspected, by the removal of the top cover plate.

The Abbot-Detroit transmission is one of the most compact and efficient change speed gears that has ever been placed in a motor car.

It has been built for severe service and for that reason will be found to be particularly adapted for hard winter use, when, on account of the changing character of the road it is necessary to shift gears often.

OTHER DETAILS

Some other things should be mentioned as important for your consideration when buying a car which you expect to drive the year round.



Rear Axle with Cover removed from Bevel Gear case. Note also Underslung ¾ Elliptic Scroll Springs.

There should be ample road clearance, an absence of projecting parts below the frame, a protected steering gear, wide flaring fenders, snugly fitted to the body so that no water or slush can get through, provision for entirely enclosing all moving parts including brakes, well-finished and upholstered bodies, close fitting wind shields and tops equipped with Jiffy Curtains, well fitted doors of clean cut design, free from places in which mud and slush can collect.

Abbott-Detroit cars are admirably suited to give all-the-year-round service.

Remember—Electric Self-Starter
Electric Lighting
Standard Equipment
on all Models

"The demand of the day is that an organization shall be judged by its product and not by what is claimed for itself."

This is our slogan. Apply it when inspecting the 1913 Abbott-Detroit Cars.

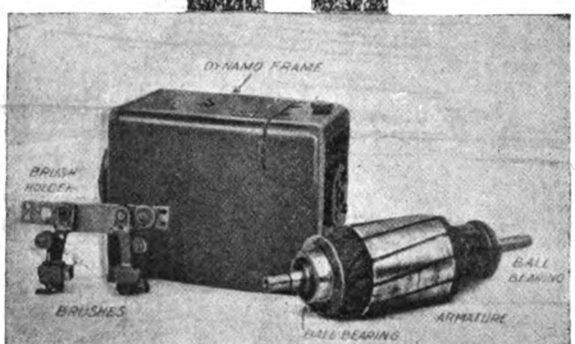
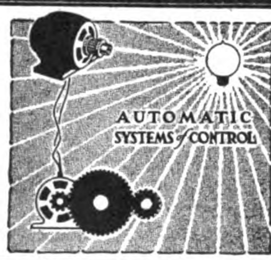
The Ward Leonard System for Lighting and Starting

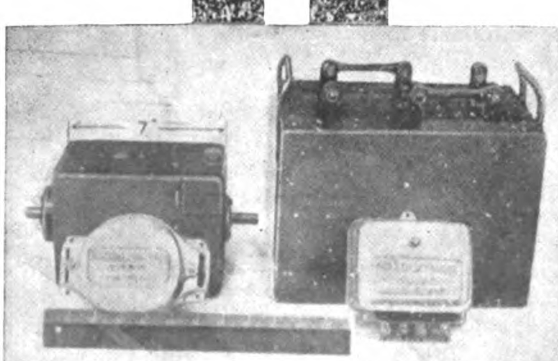
Every Trial a Triumph



· WARD LEONARD ·



· Lighting - Starting ·



Every trial of a Ward Leonard System means triumph for its designers and satisfaction for its users.

Every user—every dealer—every manufacturer realizes the need of an efficient lighting and starting system.

But each one of them wants the ultimate system, and the ultimate system will be that one which is theoretically, scientifically and practically correct.

There must be no complications, no unnecessary parts, nothing to get out of order.

The system that will answer these requirements is the Ward Leonard System.

Time and exhaustive experiments through twenty years of electrical experience have shown that the Ward Leonard System is perfect.

We realized years ago that the value of an electric lighting and starting system to the automobile manufacturer lay in the perfection of its automatic control. Our perfection of this feature stamps the Ward Leonard System as the ultimate choice of engineers.

Christmas

Clement C. Moore
James Whitcomb Riley
F. Hopkinson Smith

Henry Van Dyke
Eugene Field

Probably more grown men and women can repeat to-day: "'Twas the Night Before Christmas" than can remember any other poem of equal length in the language. They may have forgotten the name of the author, Clement C. Moore, but they can reel off the beginning glibly enough:

'Twas the night before Christmas and
all through the house
Not a creature was stirring, not even
a mouse;
The stockings were hung by the chimney
with care
In hopes that St. Nicholas soon would
be there;
The children were nestled all snug in
their beds,
While visions of sugar plums danced in
their heads.

And how these elocutionary lights, as well as the rest of us who are not vocally inclined, have revelled in Eugene Field's delicious "Jes' 'Fore Christmas."

"Father calls me William, sister calls
me Will,
Mother calls me Willi—the fellers call
me Bill!
• • • • • • • •
Most all the time the hull year round
there ain't no flies on me,
But jes' 'fore Christmas I'm as good as
I kin be!

And the pious smugness with which this interesting imp concludes is unctuous joy to the soul of the reader:

But Christmas, with its lots and lots uv
candies, cakes and toys,
Wuz made, they say, fur proper kids
and not fur naughty boys!
So wash yer face an' bresh yer hair an'
mind your p's and q's,
An' don't bust out yer pantaloons an'
don't wear out yer shoes.
Say "yessum" to the ladies an' "yessir"
to the men,
An' when they's company don't pass yer
plate fur pie again;
But, thinkin' uv the things you'd like to
see upon that tree,
Jes' 'fore Christmas be as good as you
kin be!"

"They's a kind o' feel in the air to me
When the Chris'mas time sets in
That's about as much of a mystery
As ever I've run ag'in.

Is it the bleat o' the whistle and beat
O' the little toy drums and blare
A' the horn? No! No! It is jest the
sweet—
The sad-sweet feel in the air!"
James Whitcomb Riley.

"Hang up the baby's stocking;
Be sure you don't forget;
The dear little dimpled darling,
She ne'er saw Christmas yet."

Henry Van Dyke preaches another pretty good sermon in "The Spirit of Christmas," which was published seven years ago. He says there is something better than keeping Christmas Day, "and that is keeping Christmas. Are you willing to forget what you have done for other people and to remember what other people have done for you; to ignore what the world owes you, and to think what you owe the world, to put your rights in the background, your duties in the middle distance and your chance to do a little more than your duty in the foreground; to see that your fellowmen are just as real as you are, and try to look behind their faces to their hearts, hungry for joy; to own that probably the only good reason for your existence is not what you are going to get out of life, but what you are going to give to life to close your book of complaints against the management of the universe, and look around you for a place where you can sow a few seeds of happiness—are you willing to do these things even for a day? Then you can keep Christmas.

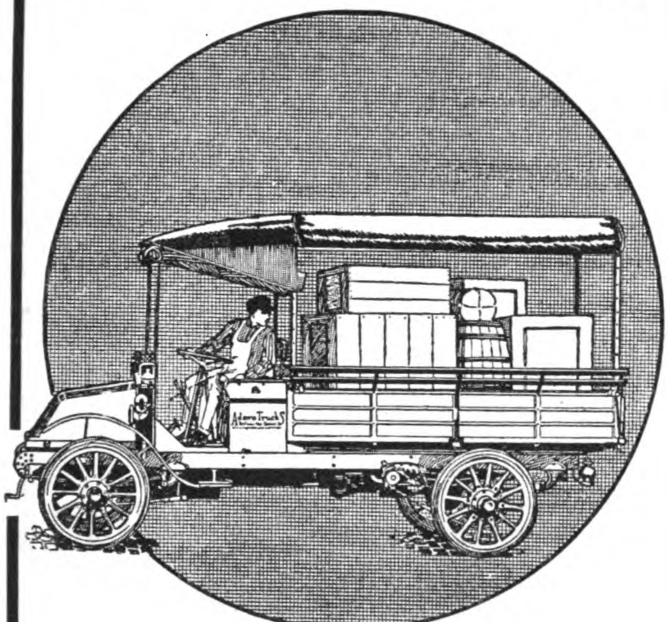
"Are you willing to stoop down and consider the needs and desires of little children; to remember the weakness and loneliness of people who are growing old; to stop asking who much your friends love you, and ask yourself whether you love them enough; to bear in mind the things that other people have to bear in their hearts; to try to understand what those who live in the same house with you really want, without waiting for them to tell you; to trim your lamp so that it will give more light and less smoke, and to carry it in front so that your shadow will fall behind you; to make a grave for your ugly thoughts and a garden for your kindly feelings, with the gate open—are you willing to do these things even for a day? Then you can keep Christmas.

"Are you willing to believe that love is the strongest thing in the world—stronger than hate, stronger than evil, stronger than death—and that the blessed life which began in Bethlehem nineteen hundred years ago is the image and brightness of the Eternal love? Then you can keep Christmas. And if you can keep it for a day, why not always?"

"And so, as Tiny Tim observed, God Bless Us, Every One!"

Says Longfellow:
"I heard the bells on Christmas Day
Their old familiar corals play.
And wild and sweet
The words repeat
Of peace on earth, good will to men!"

Adams Trucks
"Deliver the Goods"



Adams Trucks are Used in 85 Different Lines of Trade

Repeat orders from many large truck users, who have been operating from 2 to 25 trucks of different makes, demonstrate the superiority of the Adams

One owner of a number of trucks writes: "In answer to your inquiry of the 11th inst. regarding Adams Trucks, I am pleased to say it has proven the best of the bunch—I have eight. I don't know of any truck at any price that can beat it."

A New Orleans manufacturer using several other makes of trucks but who, several months ago, installed an Adams, writes: "We have finally found a truck to answer all our requirements."

Another writes: "We have had quite some experience with motor delivery cars, the Adams being our third, and we very gladly say that the Adams is the best, most reliable and cheapest to operate of any we have ever owned."

If you are not posted, why not write us direct and get acquainted with the Adams. "It Delivers the Goods."

We will exhibit at the National Commercial Car Show, Chicago, February 10th to 15th, and we invite all Merchants, Manufacturers and Dealers to inspect this line of trucks.

TRADE K-W MARK

Electric Head Light Outfit
$35.00

Complete Outfit; Generator, headlamps, switch, wire and bulbs.

Easy to install on any car with exposed fly wheel.

No storage battery required.

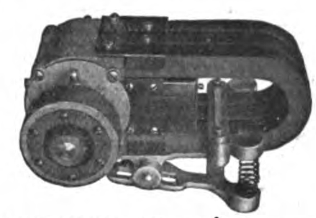
No complicated cut-out nor charging device.

CURRENT DIRECT FROM SELF-REGULATING ALTERNATING CURRENT GENERATOR.

Weight only 18 pounds. Compare this with the heavy, complicated and costly charging outfits.

MORE LIGHT AND BETTER LIGHT.

Let us describe it fully.



Model LS, $20.00. Complete Lamps, $15.00

The Lighting Special Generator

The new Model LS has one magnet less than our regular Model UL $35.00 Magneto, and is just like it in every way except that the Model LS is slightly smaller. Mode! LS will light two 2½-Ampere bulbs (two sixteen candle power bulbs). It embodies the well-known K-W construction, having no commutator, no brushes, and no sliding contacts, the only moving part being the rotor, which swings perfectly free, supported on high duty ball bearings.

FOR IGNITION. This Generator can be used in place of batteries for ignition if you have timer and spark coil.

We make a complete line of ignition apparatus including The K-W Master Vibrator and the famous K-W High Tension Magnetos—the strongest on earth. Don't simply ask for Catalogue—Tell us your troubles and we will help you.

WE PAY THE EXPRESS East of the Mississippi River or to the Mississippi on points beyond, on any of our goods, when cash accompanies the order.

THE K-W IGNITION Co.

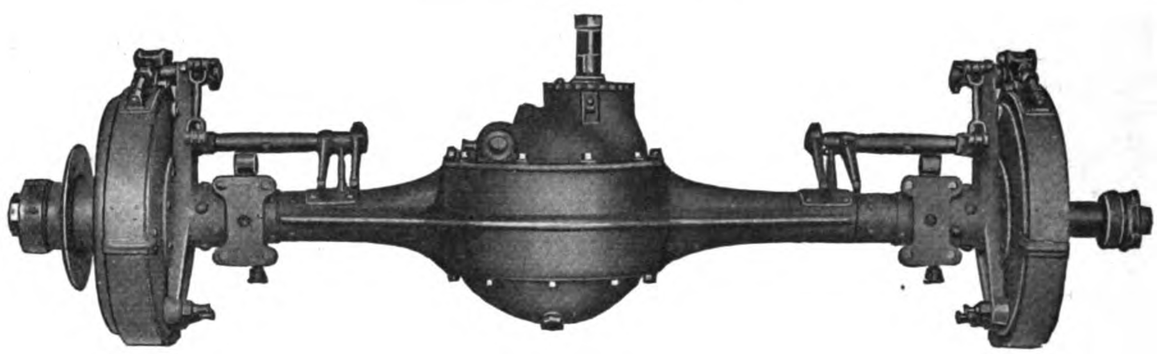
American Axles

Won't Rob Your Electric's Battery



The less current demanded to turn over your axles, the more power you have for mileage.

No electric car buyer can ignore that great truth, simply stated.

American Axles have proved that they conserve and transmit the maximum of power that any battery can give.

Ample evidence for you lies in the fact that American Axles are actually in use on 80 per cent. of the electrics in this country.

The option of Bevel Drive or Lanchester-Daimler Worm Gear can be had with American Axles only.

THE AMERICAN BALL BEARING CO.

Edgewater Park and L. S. & M. S. Ry.

American

CLEVELAND, OHIO

The Atwater Kent Ignition System

is not only distinctive from other ignition equipment in name, but it is **advantageously different** from all others in many respects.

Other ignition equipment have the distinction **without** the **difference.**

The Atwater Kent System is **different** in embodying the best features of both magneto and battery. In fact, it gives magneto results with a battery system, without the weaknesses of either, at less than one-half the cost of a good magneto.

It is ideal for use in connection with lighting and starting equipment as it produces a hot dynamic spark, perfectly timed, regardless of the engine speed.

Just a few of the many good features of the Atwater Kent System are—

Its simplicity of mechanism—no vibrators, relays or commutator—just one contact point regardless of the number of cylinders and only three moving parts, none of which are subject to excessive wear.

Its single adjustment easily and quickly made and seldom requiring attention.

Its adaptability and easy installation on any standard make of motor, new or old.

There are now two types of Atwater Kent Ignition equipment—standard Type F and the new Type K, the latter having the automatic spark control, and insulated primary circuit features.

PRICES OF THE TYPE F SYSTEM

	Standard Coil	Kick Switch Coil
1-cylinder	$17.00	.....
2-cylinder opposed	18.00	.....
2- " distributor type,	22.00	$24.00
3- " " "	25.00	27.00
4- " " "	25.00	27.00
6- " " "	27.00	29.00

PRICES OF THE TYPE K SYSTEM

	Standard Coil	Kick Switch Coil
2-cylinder	$32.00	$35.00
3- "	35.00	38.00
4- "	35.00	38.00
6- "	37.00	40.00

In substituting the Atwater Kent System for the magneto, or for driving it from any horizontal shaft or gear, we furnish a special magneto gear mounting, the additional price of which is $5.00.

Perhaps your present car needs only an Atwater Kent—"the different" system of ignition to enable it to give you perfect service. Anyhow you should have a copy of our Booklet B—it's interesting and it's free.

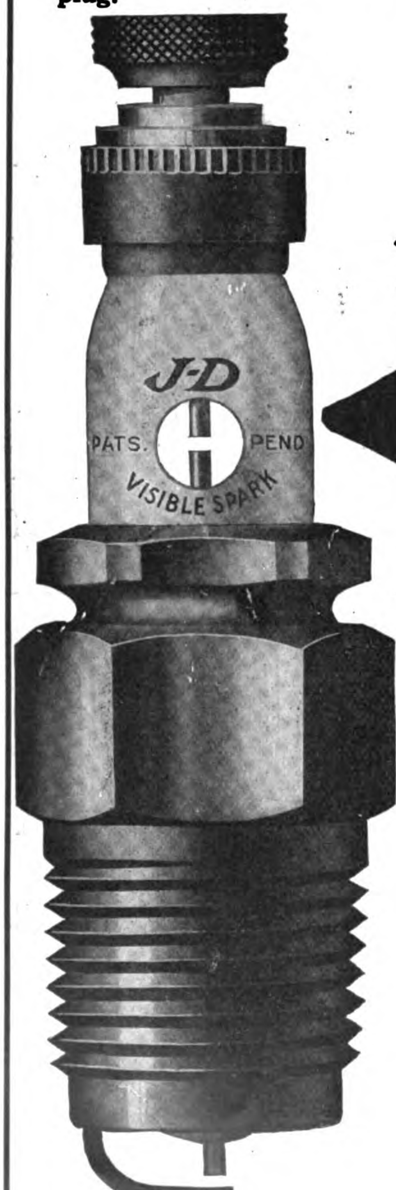
One Look Tells Everything

The J-D (JEFFERY-DEWITT CO. DETROIT, MICH.) Visible Spark Plug lays bare all ignition troubles

The "visible gap" is an open "window" giving you a full view of the internal workings of your spark plug.



If the spark is seen jumping the gap, look for your trouble between the gap and sparking point.

If there is no spark in the gap, your trouble is behind the plug—in magneto, or batteries, or coil, or wiring.

But for the "visible gap" it would take you many precious minutes—often hours—to locate the seat of trouble.

$1.00 Buys this great new Spark Plug

- Indicates in which direction trouble lies.
- Facilitates timing of engine.
- Intensifies spark in cylinders.
- Consumes only minimum current.
- Gap adjustable—can be closed entirely.
- By widening gap plug cleans itself.
- Permits regulating spark for any cylinder.
- Costs same as any good plug—$1.00.

Dealers will find J. D. Visible in greatest demand

Visible Idea Worked Out Perfectly for the First Time

The "visible gap" feature, so far as being incorporated in a plug, has always seemed as far away as perpetual motion. The visible feature has been marketed in a separate device for years, but this is the only plug embodying the visible feature in a practical manner.

It is simple. Merely a hole in the porcelain and a spiral action to regulate length of the gap in the central electrode which carries the current.

The hole in no way lessens the strength of the plug, and the current in jumping the "visible gap" loses none of its efficiency. On the other hand it intensifies the spark at the gap in the cylinder.

Additional prestige is lent the J. D. Visible Spark Plug by the fact that it is being introduced by the largest manufacturers of spark plugs in the world. We are exclusively manufacturers of spark plugs; we make millions of them each year.

The J. D. Spark Plug was a famous plug before it was improved by the visible feature. It combines finest workmanship, best materials and simplest designs.

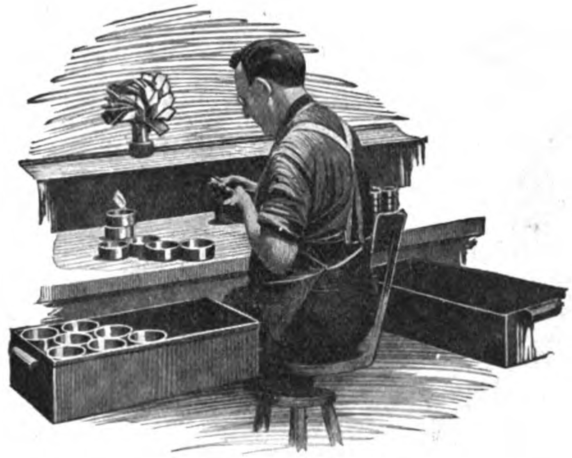
Every part of this plug is made in our factory—even the porcelain being produced in our own potteries from clays and other ingredients imported from Europe.

This unequivocal guarantee goes with all our spark plugs:

"Your money back or a new plug if you are not satisfied"

If your dealer hasn't the J. D. Visible yet, send your money direct to us for a set SPECIFYING SIZE WANTED OR MAKE OF MOTOR, and we will ship them postpaid. Remember, the J. D. Visible Plug is only $1.00. Write today for our literature on ignition. It is free.

Jeffery-Dewitt Company, 552 Butler Ave., Detroit, Mich.

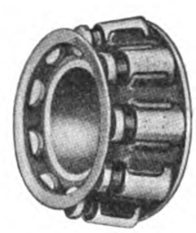


Sign of the bright red tag

¶ On the bench of each inspector is a rack full of crimson tags.

¶ Danger signals to be tied on every piece not made *exactly* to specifications; warning tags to insure that no imperfect parts shall enter the finished bearing.

Timken Tapered



Roller Bearing

¶ Here's a red-tagged 'cup' marked 'small O. D.'—date—name (Griffin) of the man who ground it. An inspector (Will Keyser) has found it to be half the thousandth part of an inch too small in outside diameter.

¶ So he tagged it red and sent it along, with other tagged parts, to the 'morgue.'

¶ 'Morgue' is the name Timken shop men give to the place where rejected parts go. It's the morgue man's task to break up those parts so they never can come, by possible chance, into use in the Timken Bearing.

¶ Twelve operations make the part called the 'cone.' Twelve inspections are given to *know* each dimension, each angle, is right. Let the slightest error occur at any step of the way—an inspector will spot it and—tie on the red tag quick!

¶ Long before such care was used, the Timken principle of tapered rollers revolving between a tapered cup and a tapered, two-ribbed cone gave a unique type of bearing that won marked success over all other kinds.

¶ In the years that have followed, Timken care *in every detail* of the making has added a hidden value that's only revealed in a life-time of good service.

The Timken Roller Bearing Company

Canton, Ohis, U. S. A.

The only axle manufacturer licensed to make automobile axles equipped with Timken Roller Bearings is the Timken-Detroit Axle Company

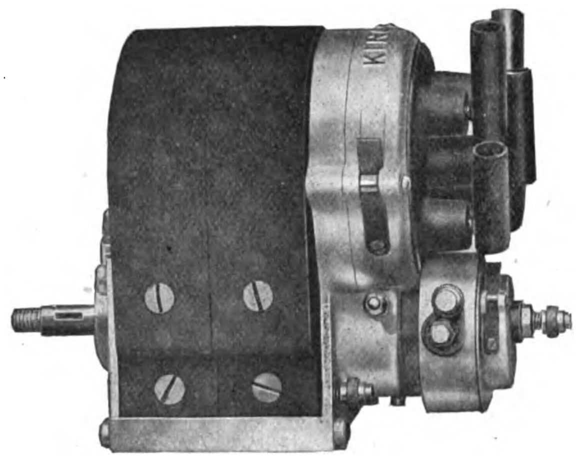
Batteries for Starting Are Out of Date



Model "B" Magneto

THE KINGSTON Magneto is all that is needed to start any car. It is rapidly displacing batteries which at best are only a needless complication. Discard your batteries, intsall a KINGSTON and enjoy peak-load motor satisfaction.

The Magneto That Put the Fat, Hot Spark on the Map

An important feature of the KINGSTON Magneto is the variable spark advance. Despite many attempts to eliminate this feature from the magneto, it has been found that without such advance the highest engine efficiency cannot be secured. The ignition time of the KINGSTON Magneto is not only variable to suit the speed of the engine, but is perfectly exact.

Another advantage is the armature construction which results in an effective spark being produced when turning as slowly as 50 R. P. M. This makes it easy to start on the first turn of the crank, and reduces the effort of cranking to a minimum. It also permits the engine to run unusually slow, and obviates the necessity of gearing down in city driving in order to keep the magneto up to firing speed.

Let us explain other details.

Write us your ignition troubles. We'll be glad to diagnose and prescribe for them. Our entire Engineering Department is at your service.

KLINE KAR
THE value of an automobile both to owners and dealers lies not in the reputation of its makers, but in the real merit of the car itself. This is just the reason why the KLINE KAR means satisfaction to the user and tremendous financial return for the dealer. No greater combination of beauty, efficiency and durability has ever been turned out of any factory.
We have thousands of testimonials from satisfied users proving conclusively that KLINE KARS are built to satisfy and to stand up.
KLINE KARS have features of construction which positively stamp them as being ahead of their time. The economical transmission installed in all our models is one of the wonders of automobile engineering. It gives direct drive on third speed and means a tremendous saving of power. In addition to this, everyone of the models is equipped with enclosed valves, a complete electric lighting outfit, auxiliary rear springs, and an automatic mechanical starter.
These are some of the strong points of KLINE KAR design and equipment. Back of them stands the KLINE quality and the KLINE guarantee, which means satisfaction to users and a surplus of profit to dealers.
Our models include two, four, five, six and seven passenger bodies with four or six cylinders.
Prices $1850 to $3500.

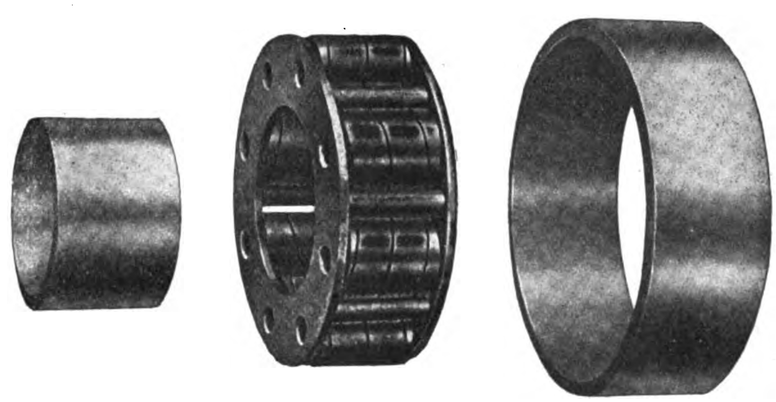
Hyatt Quiet Bearings



HYATT High Duty Type Bearings are best for transmissions because:—They have never failed in transmission service—Once adopted for use in transmissions, they have never been replaced by any other make; they have, in many instances, replaced other bearings—They reduce noise—They possess superior lubricating qualities found in no other bearings—Their cushioning effect relieves gears and shafts of undue strains, reducing excessive and unnecessary wear.

High efficiency, first cost, dependability,—each and all of which make bearing value, are not claimed as exclusive Hyatt features—but in practical value—the proper proportioning of all these factors and in ability to enable the Motor Car Builder to meet present conditions—the Hyatt Roller Bearing is claimed superior.

Larger—Roomier—More Powerful

This is the Marion de luxe—a car every motorist must consider and compare. It is one of the most interesting automobiles in the 1913 series. It offers at a moderate price a big successful touring car with every item of equipment.

It has electric self starter, electric dynamo lighting system, electric horn and many features for which an additional charge is usually made. Moreover it is roomy, stylish and comfortable. It is quiet and economical.

Look at it! Where else can you get at this price its graceful lines, rich color, spacious body and dependable chassis. To obtain another car as well known and well built with its advantages would cost you much more money. The expenditure of the same amount would give a machine not the equal of the Marion 48-A.

Marion cars were good *ten years* ago; they have been better each succeeding year; they are better now than ever. The Marion Company is a firmly established and highly regarded concern. Its dealers are reputable business men.

Do not miss an opportunity to see this handsome, reliable, luxurious Marion 48-A. You'll enthuse over it, too. Ask us about its details. Get or send for a Marion book.

We offer to established automobile dealers or to business men desiring to enter the trade upon a substantial basis, the fairest sales agreement ever written. Ask about our territory.
